Right off the bat, we gather discourse question content, Then utilizing point, we deliver a watchword based scanning for the ideal answer, on the off chance that not discovered, it hunting on Google down an answer. For instance, We set an inquiry 'what is your name' and answer is 'my name is BONGO' .at that point we ask 'your name' .it produce key your and name and it scans our application framework for answer and afterward it discovered its watchword with our inquiry and return answer content and the content go to content to discourse framework. Tragically, when asking content watchword don't coordinate, at that point return 0 and when it discovered 0 it looks on Google for reply .even it not discovered, at that point, it stores learning framework, for learn for its answer. There are described some important parts of the control of the BONGO robot.

- Artificial Intelligence part code

```
public class Main {
public Main() {}
public static void main(String[] args)
{MagicStrings.root\_path
= System.getProperty("user.dir");
System.out.println("Working Directory
= " + MagicStrings.root\_path);
AIMLProcessor.extension
 = new PCAIMLProcessorExtension();
mainFunction(args);}
public static void mainFunction
(String[] args) {
String botName = "super";
String action = "chat";
System.out.println
(MagicStrings.programNameVersion);
String[] timer = args;
int bot = args.length;
for(int i$ = 0; i$ < bot; ++i$) {
String s = timer[i$];
System.out.println(s);
String[] splitArg =
s.split("=");    if(splitArg.length >= 2)
{String option = splitArg[0];
String value = splitArg[1];
if(option.equals("bot")) {
botName = value;
                                }
.....................
.....................
```

- Describe Artificial Intelligence part

1) Our speech AI part contains below part- speech collects, train data, predict the requested data with trained data, predict the high accuracy present answer.

2) First, we collect human speech text using Google API. Then we compare with this text within our train data using neural technic. If this is founded with high accuracy, then we collect this answer. Otherwise, we try to collect within Google and Wikipedia using summarizing question keyword.

3) Our image processing part-collect image, detect as unique human or animal, store in our system file storage.

4) First, when a human stand in front of this robot. if a human trying to question him or introduce to him, the robot takes an image of this human and store this picture. using OpenCV and analysis this picture with our previous train picture or data, if it corresponds with our train data. identify this human. Else it recognizes as an unknown person. Collect these personal data for future analysis.

Example: A human face in front of him, and tell it, do you know me, it takes pictures to frame in a different angle, then analysis it for identify this person, answer according to train data information, otherwise answer is random, no, you are an unknown person, etc.

- Some examples of robot command part code

```
if(data.get(0).toString() != " ")
{String command = data.get(0).toString();
String response =
chat.multisentenceRespond(command);
muteAudio(false);
String res = new EngSearchAndResult().
ProcessResult(data.get(0).toString());
MainActivity.t2.setText
(data.get(0).toString());
if(command.indexOf("handshake") != -1 ||
command.indexOf("hand shake") != -1||
command.indexOf("hand shake with me")
!= -1||
command.indexOf("can you hand shake")
!= -1){
bt.sendMessage("A");}
else if(command.indexOf("head") != -1 ||
command.indexOf("Head") != -1){
if(command.indexOf("turn") != -1){
if(command.indexOf("right") != -1) {
bt.sendMessage("C");}
if(command.indexOf("left") != -1) {
bt.sendMessage("D");
}       }}
```

```
else{
if (command.indexOf("tell") != -1) {
if (command.indexOf("about") != -1) {
if (command.indexOf("yourself") != -1 ||
command.indexOf("your self") != -1) {
bt.sendMessage("B");
}}}}
.....................
.....................
```

We can see from Fig. 10 speech recognition flow chart. The robot can take the speech of the people from the microphone then process by the microprocessor. The people speech will match by specific programming command if the specific speech match then the robot can do the work, otherwise, the robot can tell "sorry, please repeat again".

IV. RESULTS

The BONGO robot can execute the following work :

- The BONGO can understand both Bengali and English of any questions and given the answer.
- The BONGO can response when it gets instructed such as a handshake, catch object by hand, move fingers by the voice command.

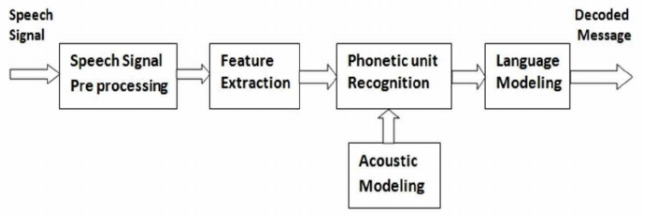

Fig. 10. Speech recognition

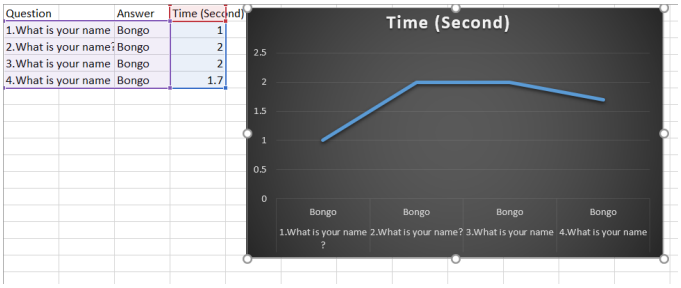

Fig. 11. The experiment of how much time the robot needs to answer the question

- BONGO can interact or communicate with a person as like Sophia robot.
- BONGO can move the head by direction of human command.
- BONGO can recognize the human voice.
- BONGO can calculate general mathematics and answer it.
- BONGO can answer any question searching from google. So the robot can answer everything that sometimes people does not know it answers.

Fig. 11 shows a sample question experimental result where we observed that there are different time need for same question answer of the robot. This answer response time generally depends on internet speed and how much noise of the environment.

Now, We have done this robotics camera experimental shot when collecting the object detection picture as a unique person. Then this picture can be matching with our storage folders image file successfully. We use fingerprint hashing image technic to detect an image uniquely. Fig. 12 shows the Image recognition experiment of two persons, where it can indicate a specific id of each person.

V. CONCLUSION

In this paper, we demonstrate that the utilization of the BONGO in reality. The structure and development of the BONGO utilize the exceptionally incorporated inserted framework and Artificial Intelligence. This robot accomplished some sort of new highlights which not present the Sophia till now. It can likewise compute general arithmetic and reply. This robot can move all heading as like left, right, in reverse and forward by the guidance of human voice. This robot camera detects to collect the image face reorganization of persons or animals.

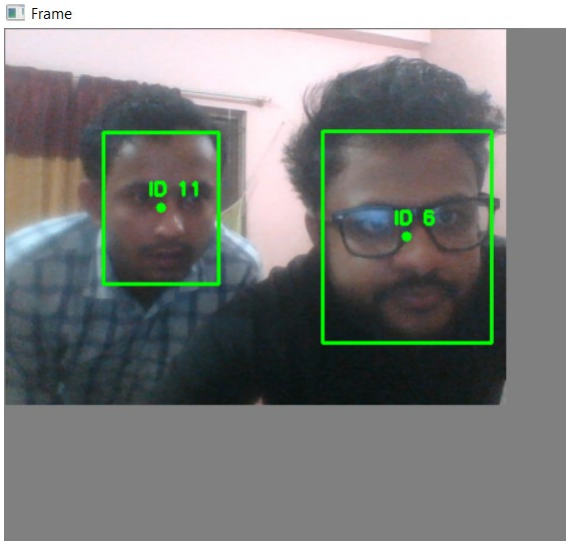

Fig. 12. Image recognition experiment

The power utilization of the robot up to 5 hours keeps on providing power by DC 12 v Battery.

VI. FUTURE WORK

We will attempt to headway BONGO robot as like progressively human lead and agreeable with people. The looking great structure will make for the robot. There need to consolidate the legs for passing on a dissent beginning with one place then onto the following and moreover effortlessly walk. We are additionally are attempting the robot will ready to keep away from the snags and easily stroll by 3D picture preparing [6]. The robot likewise causes individuals to discover an area and provide the guidance of wherever. It can likewise utilize his hand and do some basic work. We will contain the online structure by then trust that the robot will be prepared to answer the unpredictable request. We will in like manner endeavor to enhance the BONGO for therapeutic, incitement, excitements, military explanation behind different sort's business application.

ACKNOWLEDGMENT

We are particularly appreciative to go with people who support us for fiscally makes the BONGO robot. Bangladesh University of Business and Technology and Japan-Bangladesh Robotics and Advanced Technology (JBRATRC) jointly financially helps for making the robot.

***Abstract*— Surveillance of international border areas, industries, banks, shopping malls, and any other suspected areas is a difficult task to be done. It is not possible to scrutinize everything at each and every moment. In this case, a requisite solution can be a robot which automatically detects any suspicious activity or condition and reports to the control unit. This paper is on a bipedal surveillance robot which can budge in an area, send images and videos even in caliginous condition by using night vision mode of the Wi-Fi camera as well as the installed sensor on this robot provides gaseous parameters of the area such as the amount of Methane, LPG, Carbon mono-Oxide. The robot has a wireless Bluetooth module for communication and collection of data. The whole process can be run on a voice command system. After the data collected from the robot, data are appraised and analyzed to get an understandable idea of the surveilled area.**

Keywords— Surveillance Robot; Bipedal Robot; Gas Sensor; Night-Vision camera; Voice Command; Wireless Communication.

I. INTRODUCTION

From the dawn of civilization, there were always problematic activities that imbalance the whole socio-economic stability of a country. Terrorist attacks or Trespassing of the border is one kind of these problems. In many times, it is seen that the surveillance of these situations get very condemnatory as law-enforcers cannot get to the place at the right time. Even if they can reach, they may face a deadly counter-attack there. Some such kind of incidents occurred in Dhaka when some militants took over a café named as Holey Artisan café [1-3] or Rohingya trespassing from Myanmar into Bangladeshi border [4-6]. The multifaceted employability of robot has brought the chance to send them in a place where human life can be at stake. However, with the modernization of robotic technology, the appeal towards the human look-alike robot is increased. Bipedal Robot with the advantages like more energy efficiency [7-8], better handling capacity of the rough terrains, more maneuverability and better Human-Robot Interaction (HRI) [9], has emerged as one of the interesting research sectors in the robotics field. A chemical attack is another recent problems arising across the world [10-11]. Sometimes it is been treated more dangerous than nuclear weapons. So, it is now a crying need to sense the presence of the toxic gases in a place. Any chemical attack can be breached by avoiding the place by sensing the levels of toxic gases like Carbon-Di-Oxide (CO2), Carbon mono-Oxide (CO) and Methane (CH4) of the specific place with the use of the gas sensors. If the still pictures or the motion pictures can be found through any system then it would be more planned to counter these havocs. But the surveillance could have been done with perfection if there were any availability of surveillance robot system. With all these, there is another feature that can be developed and that is the Voice Control [12] which makes the whole system more efficient and encrypted as it gives the system a massive advantage which is to control it from a significant and safe distance. In our project, we will try to seek out these problems with the help of a Bipedal Robot which can go to a place without any human intercession where the gas sensor and night vision Wi-Fi camera are installed on it to get the data about the gaseous condition, images and videos even if in the obsessed situation. Bluetooth module is used to send the Voice Command and to transmit the data. The project also illustrates the ways to develop a Bipedal Robot and also dispenses the data transmitted from the robot during its exploration.

II. LITERATURE REVIEW

Above last decades, many researchers have designed different purpose soldier or surveillance robot. Soldier or surveillance robot is a robot which does the surveillance of International border areas, war field and terrorist activities [13]. Arduino controlled war field spy robot using night vision wireless camera and Android application is very muchly used nowadays [14]. For the implementation of this robot night, vision camera is used for monitoring and for operating Bluetooth module is used. Implementation of Spy Robot for a surveillance system using internet protocol of raspberry pi where sensors are used to detect the living object and night vision camera is used to capture the pictures of the object [15]. Wireless Controlled Military combat Robot system is a work where the micro wireless camera is fitted and where the video and voice transmitted to the control room by using the Bluetooth Module [16]. The bipedal structure is another recent conception in this sector to give pace to this specific robotic research [17]. It is done to avoid the obstacles on the way to the target. Rough terrain can be topped as like as human leg behavior by this structure. Along with this, Voice command is now playing a vital role in the establishment of a surveillance robot with more perfection [18]. Bipedal Structure has the advantages over the wheel based robot as it has the lighter weight, has higher efficiency as it has the less number of the actuator and better Human-Robot Interaction (HRI). Along with this Voice, command helps the user to control the surveillance robot from a distance which can be very significant. Android applications are made to provide the voice command by using Bluetooth Module

[19]. In addition, Arduino Movi-Shield, RF Transmitter Receiver Pair 433 MHz-RXB6, ZigBee communication modules are also used to transmit the voice command to the robot. The proposed robot can capture still images and videos by using night vision camera which also makes it perfect to send images and videos even in the night time. It can walk in unprepared terrain which is inaccessible for robots with wheels or caterpillars. It has the Gas sensor which is capable of providing data of the gaseous condition of the area under surveillance. The implemented robot is using Bluetooth module with Android platform for controlling purpose as well as to transmit the voice command.

.

III. Proposed Methodology

The upliftment of the research work is divided into 3 stages. They stand as mechanical, electronic and software portions after considering the plan for making a research work on the topic named Voice Command Based Bipedal Surveillance Robot. The upliftment procedure is represented in Figure 1. The Mechanical stage is divided into the parts as pursues:

- Design of Model
- Build the prototype
- Upliftment of Model Hardware

The Electronic stage is divided as pursues:

- Design of Circuit Diagram
- Circuit Simulation
- Upliftment of Circuit

In the software stage, an algorithm is designed as per as the plan and the programming is sorted according to the algorithm.

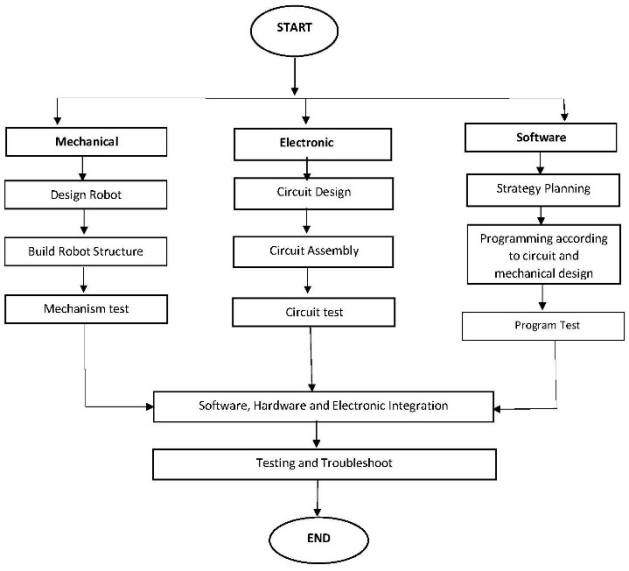

Fig. 1. Methodology of a Bipedal Surveillance Robot

IV. Proposed System Design

By taking into account its better performance over long distance data transmission from the working station the proposed robot is designed so that the user can take the idea under the surveilled area and can control the robot. Block diagram of the proposed system shown in Figure 2 & Figure 3.

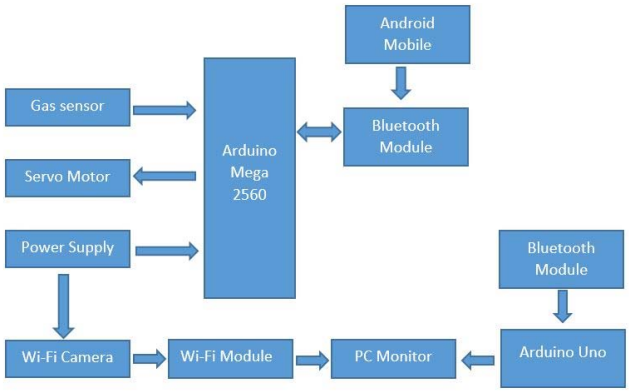

Fig. 2. Block Diagram of the Proposed System

The robot is controlled by voice command using a Bluetooth module. Voice command is transmitted by an android application. The robot collects gaseous data by a gas sensor and sends to the user with the help of the Bluetooth module as well as the robot sends the video using a smart wifi camera with night vision mode which enables it to operate even in the darkness.

In the process of building a surveillance robot, both mechanical structure and electronic components are needed

A. Mechanical Structure

In the proposed model, Acrylic plastic sheets which have 2mm thickness are used to build the structure of the model. On account of lightweight and better flexibility, this sheet is considered. In the purpose of movement, 6 metal gear servo motors are used in hip, knees, and ankles of both legs. Figure 3. shows the 3D model of the proposed system.

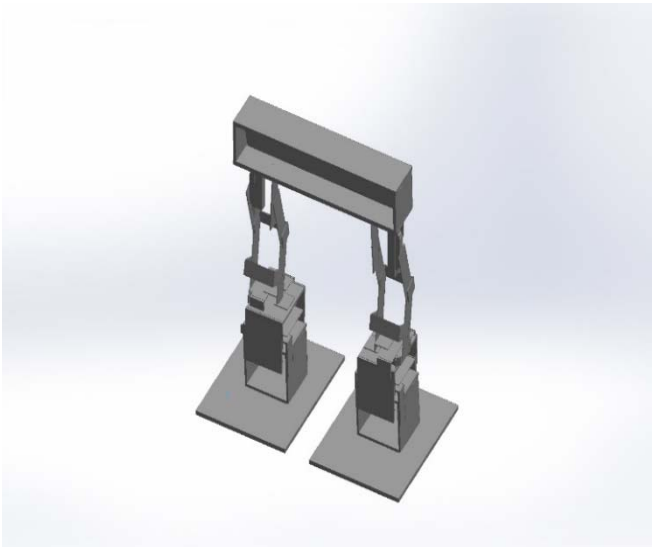

Fig. 3. 3D Model of the proposed system

B. Electronic Components

On the purpose of transmission, sensing and controlling motive, there are some components which are used and their names are given below:

- Arduino Mega 2560 and Arduino UNO
- Gas Sensor(MQ-5)
- Servo motor
- Bluetooth Module(HC-05)
- Wi-Fi Smart Camera

C. Design of Circuit Diagram

The circuit diagram of the proposed system exposes in figure 4. PROTEUS® software is used to design and partial simulation of the circuit. Since there was no way to simulate gas sensor with the presence of real gas, the simulation of gas sensor was do/-*
ne by imitative binary input to the Arduino. At the time of implementation, the circuit diagram had been modified which was designed in the simulation software. After the completion of the design, simulation and implementation of the circuit in the robot, the expected result has come out.

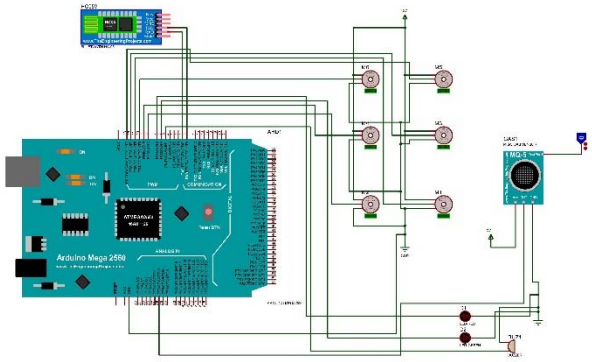

Fig. 4. Circuit Diagram of the Proposed System

D. Gas Detection

Toxic gases in the air are addressed in the microcontroller and the amplitudes of their concentration were measured by using gas sensors. To measure the specific gas concentration, the sensor indicates the result as the reference point or scale in a Concentration versus Time curve. When any toxic gas is found in the air, an alarm is rung by using a buzzer. There are two types of gas sensor have found. One is an electrochemical gas sensor which is used for detecting LPG, CO_2, CO, CH_4, etc. and another one is metal oxide semiconductor (MOS) which is used for inflammable gases.

V. Hardware Implementation

Figure 5 shows the final implementation of the robot after the development and combination of mechanical construction and circuit diagram. Hither Arduino Mega 2560 board and Bluetooth module are used for controlling the robot and transmitting and receiving data respectively. The gas sensor is used for detecting the toxic gases as like as LPG, CO, CH_4. In this project, the most complicated part is the movement of the robot accurately. Stabilization is done by using proper materials and following correct procedures of building it.

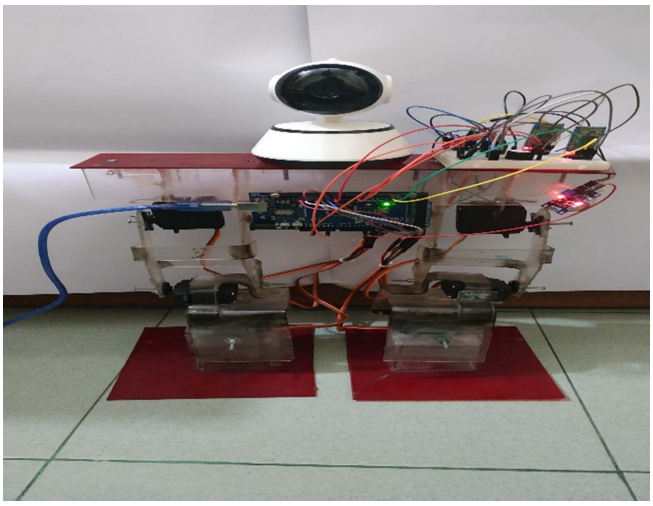

Fig. 5. Implemented prototype of the Robot

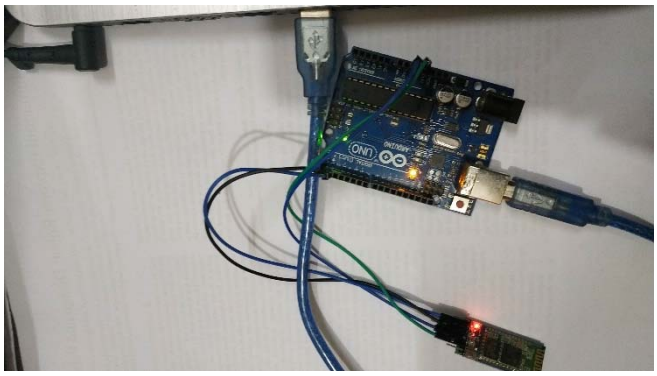

Fig. 6. Implemented Gas sensor Data Collecting station

Figure 6 shows the gas sensor's data collecting station. Here Arduino UNO and Bluetooth module are used to receive the data of the gas sensor.

VI. Software Description

Various types of software have been used for mechanical design, circuit design, real-time data analysis which are:

- Arduino: Arduino is an open source electronics platform by which many types of sensors, motors, lights, etc. can be controlled. Two types of Arduino Board have been used for the robot.
- Proteus: For Circuit Design and Simulation, it is a famous software. Since the software is easy to design and simulation, it's used for the simulation purpose.
- Blender: For 3D character design, Blender is a compatible software. Using this software, the 3D design of the robot is drawn.
- MATLAB: It is a multi-paradigm numerical computing environment and fourth-generation programming language. It is used in this project for the purpose of plotting of the collected data from the receiving module of the gas sensor.

- Android Application: An Android application is a smartphone software which runs in the Android OS platform. In this project, an android application is used to transmit the voice command with the help of Bluetooth connectivity. Figure 7 shows the android application which is used to transmit the voice command using google voice command.

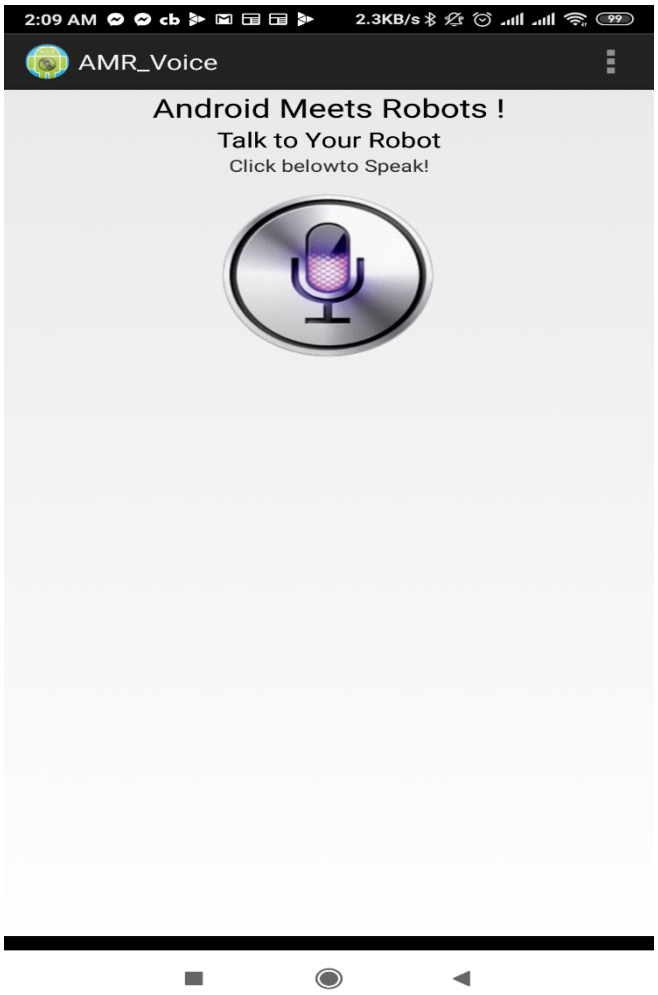

Fig. 7. Android application

VII. Experimental Result

The main goal of this project was to develop a robot which can be sent to a place where surveillance is needed and to know about the condition of this place by video streaming continuously and sensing the condition of toxic gases in the air of this place by it. It was a must to give it a capability to send data to the user by which the state of the place can be both analyzed and realized. It was not possible to conduct this environment in any real field area. So, we created an artificial environment to test this robot. The video streaming is shown in figure 8. It can send data in both bright and dark condition using night vision mode which makes the robot capable of operating in 24 hours of a day regardless of the light condition.

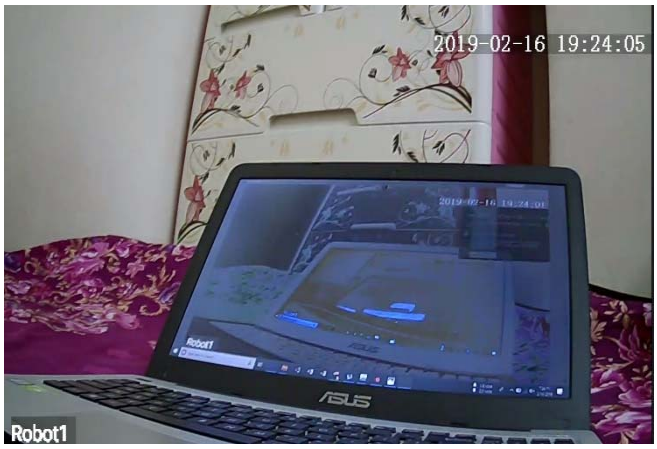

Fig. 8. Video streaming of the surveillance place

The Collected data from the gas sensor illustrated here:

a) Methane Gas (CH_4): The Methane gas variation is respected to time which is shown in figure 9. The amount of methane gas varied from 0-500 ppm. The result is shown in figure 8.

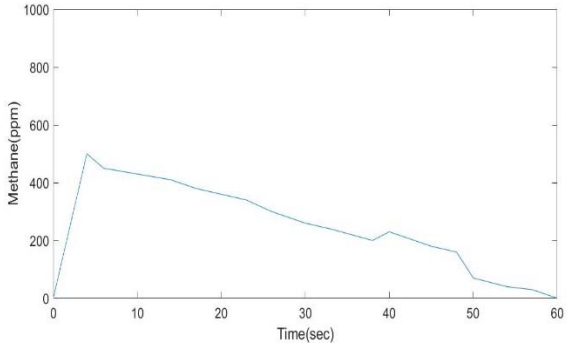

Fig. 9. Change the amount of Methane Gas over time

a) LPG: Figure 10, Shows the amount of LPG gas which was varied from 0-800 ppm. Release of the LPG gas and the decreasing rate of it can be analyzed from the plot.

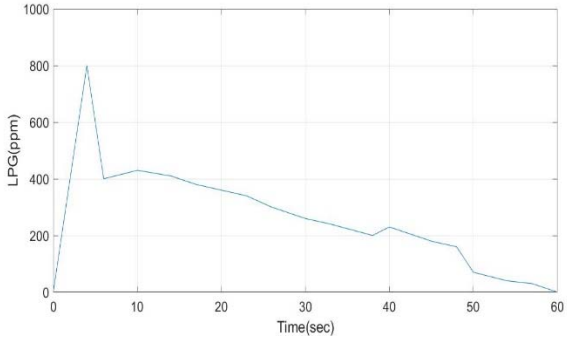

Fig. 10. Change of the amount of LPG Gas

b) Carbon mono-Oxide (CO): In figure 11, it shows the amount of CO gas over time. It varies from 0-430 ppm. By the figure, get a clear idea about the rate concentration of CO in the air.

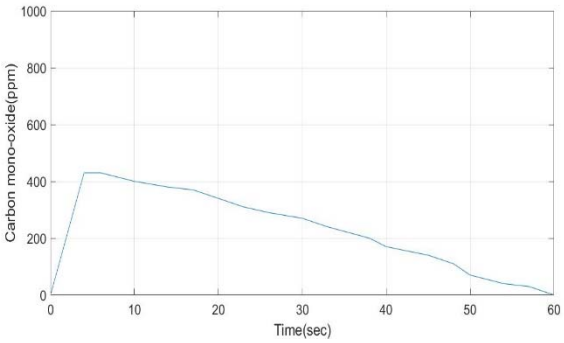

Fig. 11. Variation of the amount of CO over time

VIII. CONCLUSION

The experiment was taken in a room so the actual data is not collected. Without this, the project covers all types of design and development. It can detect LPG, CH_4, CO. through the sensor. To analyze this data get a clear idea about the environment. By the video streaming know the condition of the place. It might be a suitable one because of walking in unprepared terrain where wheel robot is faced with difficulties.

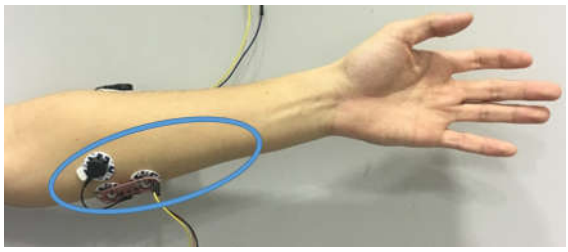
***Abstract*—This paper presents a low-cost myoelectric robotic hand which was developed by a 3D printer. The purpose of the developed system is to be used as a low-cost prosthesis. It is controlled by electromyogram (EMG) signals from flexor and extensor muscles in the lower arm. Each part of the robotic hand is created using the 3D printer. Arduino MEGA microcontroller is used as the main controller. Experimental results show that the robotic hand can perform the objects grasping operations according to EMG signals from muscles without dropping the objects in the experiments.**

Keywords—robot hand, EMG signal, 3D printing, a prosthesis

I. INTRODUCTION

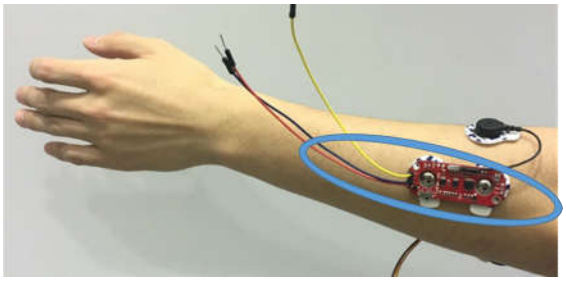
The limb loss is the problem that occurs on a large scale in every year. There was an estimation that 1.6 million people in the United States were living with the loss of limbs in 2005, and this number has the possibility to be doubled by 2050 [1]. Prostheses are devices which replace the lost limbs. Persons who suffer from the loss of upper limbs may require prosthetic arms or prosthetic hands to replace their missing limbs. There exists a significant number of researches on prosthetic limbs. Such research includes the classification and implementation of EMG signals from human arm on a prosthetic hand [2], the design and development of the prosthetic limb which controlled by EMG signals from muscles near the human shoulder [3], an implementation of the actor-critic reinforcement learning method for controlling prosthetic arm movements using EMG signals [4], the development of the hybrid prosthetic arm controlled by signals from the human brain [5], an application of the force sensor for sensing purpose on prosthesis [6] and the design of the prosthetic hand that can grab multiple types of objects using a single actuator [7]. Among the methods for controlling prostheses, myoelectric is one of the widely applied methods. Users of the myoelectric prostheses can use the EMG signals from their muscles to control their prostheses, which can be seen from [2], [3], [4], [8] and [9].

Despite the number of prostheses research available, the majority of the works have overlooked one problem: the cost. The cost problem can lead to less accessibility to the prosthesis. Recently, the application of 3D printing has spread throughout many fields of researches. The use of 3D printing allows the manufacturing of objects to be more simple, cheaper and more versatile. Varieties of 3D printing implementations can be found such as digital forensics [10], robot parts manufacturing [11-12], and prosthetic limbs manufacturing [13-14].



We propose the 3D printed myoelectric robot hand that controlled by EMG signals to achieve the goal of developing a controllable prosthetic hand with low production and low maintenance costs. Parts of the proposed robot hand are created from the 3D printer. For controlling the robotic hand, EMG signals are received from muscles in the human lower arm. The developed system was tested with two experiments on the grasping tasks: plastic bottle and small computer mouse. The initial tests of the robotic hand gave satisfactory results.

Remaining parts of this paper are divided into sections as follows: section 2 illustrates the EMG signals implemented to the robotic hand. Section 3 describes the components of the proposed robotic hand. Section 4 displays experiments and the experimental results of the robotic hand. Finally, section 5 concludes matters in this paper and discuss the future works on the proposed robotic hand.



II. IMPLEMENTED EMG SIGNALS

EMG signals are emitted from the contraction of muscles. The proposed robotic hand utilizes EMG signals from two muscle groups in the lower arm: flexor muscle and extensor muscle. Muscle sensors need to be placed around the specified muscles, one sensor for each muscle. In this paper, two MyoWare muscle sensors are applied for receiving EMG signals. Fig. 1 shows the locations of muscle sensors on the human arm, where locations of sensors are marked with circles. Fig. 1(a) indicates the sensor location for the flexor muscle and Fig. 1(b) for the extensor muscle.

We tested the muscle sensors with two simple operations: hand closing and hand opening. During the tests, EMG signals were received from the human arm and displayed as graphs. Fig. 2 shows graphs of the received EMG signals, where the blue line refers to the signal from flexor muscle and the red line is from the extensor muscle. The green square in Fig. 2 marks the EMG signals at the normal level when the human arm is relaxed. The blue circle and red circle areas show the EMG signals when the human hand is closed and stretched open, respectively. From the graphs, the EMG signal from flexor muscle is significantly stronger than the normal level when the hand is closed. On the other hand,

(a)

(b)

Fig. 1 Muscle sensors locations on human arm muscles: (a) flexor muscle (b) extensor muscle

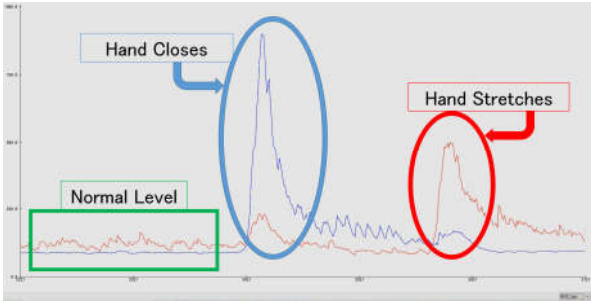


Fig. 2 EMG signals from two arm muscles (blue: flexor muscle, red: extensor muscle)

the amplitude of the signal from extensor muscle is greatly increased from the normal level when the hand is stretched.

These characteristics of EMG signals can be used for controlling the robot hand to perform simple actions. In this work, EMG signals are used as the trigger for two actions: hand closing and hand opening. The activities of the signal from flexor muscle are applied for the hand closing action, while the hand opening action is performed regarding the signal from extensor muscle.

III. Proposed Myoelectric Robotic Hand

The overview mechanism of our myoelectric robotic hand is displayed in Fig. 3. The system flow starts from the muscles in the human arm where muscle activities emit EMG signals. The EMG signals are detected by the MyoWare muscle sensors, then sent to the main controller. We used the Arduino MEGA as the main controller of the robotic hand. After receiving the signals, the main controller moves small servo motors according to the EMG signals. These small servo motors are located inside the robotic hand. Once the human user closes their hand, the robotic hand also performs the hand closing action. In contrast, the robotic

TABLE I. Robot Hand Specifications

Attribute	Specifications
Dimensions	326.0×84.5×77.0 mm
Weight	732 g
Smallest Grasp	20×20 mm
Sensors	2 MyoWare Muscle Sensors
Motors	6 SG90 Servo Motors
Controller	Arduino MEGA

hand performs the opening operation when the user stretches open their hand. The hardware and software of our robotic hand are described in following subsections.

A. Mechanical Design and Components

We designed all parts of the robotic hand on SolidWorks 2015. The parts were printed from XYZprinting da Vinci 2.0A Duo 3D printer. The printed parts include the frame for the main controller, two movable fingers, and an immovable thumb part. Fig. 4 illustrates the appearance of the robot hand. Table 1 describes the specifications of the robot hand. The robotic hand is 326.0 mm in length, 84.5 mm in width and 77.0 mm in height, with the weight of 732g. The smallest object that the robot hand can grasp is at the size of 20×20 mm. Arduino MEGA is installed inside the frame part to work as the main controller. There is one battery socket installed along the Arduino MEGA to power the controller. Two MyoWare muscle sensors are connected to the main controller through the wired connection. Six SG90 servo motors are placed in six joints of two movable finger parts. All six servo motors are connected to the main controller through the wires. These servo motors are directly powered by four 1.5V batteries from the external battery

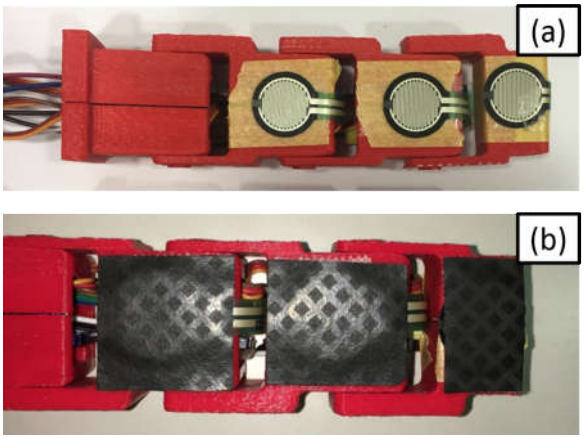

Fig. 5 Moveable finger parts: (a) with pressure sensors, (b) with anti-skid rubbers

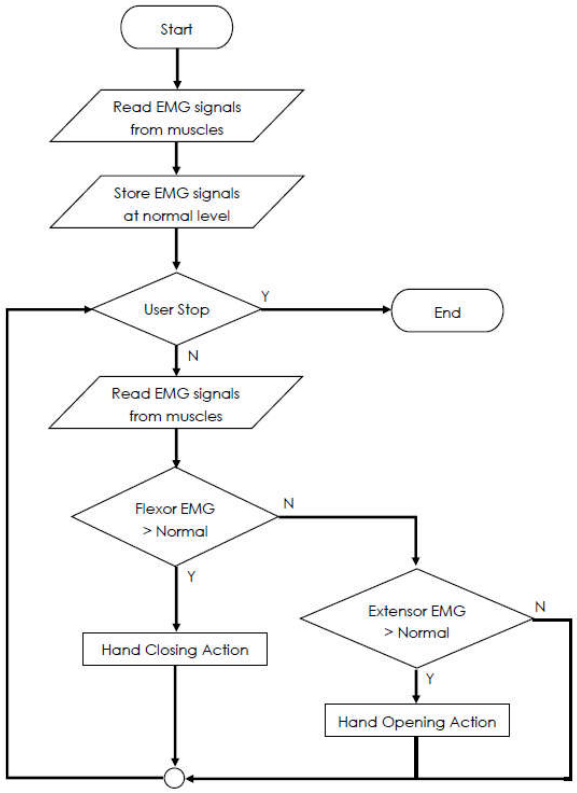

Fig. 6 Flowchart of the robotic hand software

sockets. To hold the robot hand with the human arm, the robot hand is also attached with two adhesives nylon tapes. There are three switches installed to control the hand: the power button, start button and stop button.

Fig. 5 shows two movable finger parts. There are two fingers available in the robot hand. The SG90 servo motor is attached to each joint of the finger part. The surface of each finger is attached with a set of pressure sensors shown in Fig. 5(a). These pressure sensors give the robot hand an ability to grasp an object with the proper amount of force. An anti-skid

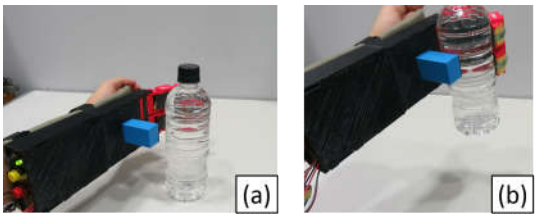

Fig. 7 Grasping of the plastic bottle: (a) before grasping, (b) during grasping

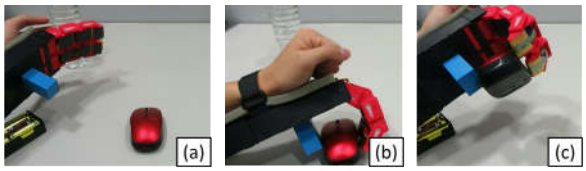

Fig. 8 Grasping of the computer mouse: (a) before grasping, (b) grasping (top), (c) grasping (bottom)

rubber sheet is placed on top of each pressure sensor to prevent the grasped object from slippering, as in Fig. 5(b)

B. Control Software

Software for controlling the proposed robotic hand is written as a single Arduino program, in which the core algorithm relies on the activities of EMG signals. Fig. 6 describes flows of the robotic hand software. The process of software part starts from the initialization, in which the EMG signals at the normal level are recorded. The EMG signals at the normal level are stored to be used as the reference. The robotic hand then progresses to the main process. In the main process, the robot hand continuously retrieves EMG signals from flexor and extensor muscles. If the signals from flexor muscle are stronger than the stored reference, the main controller triggers servo motors for the hand closing action. On the contrary, the hand opening action is triggered when the retrieved signals from extensor muscle are stronger than their reference. The process stops once the stop button on the robotic hand is pressed.

IV. Experimental Results

The robotic hand was tested with two object grasping tasks: 500 ml plastic bottle grasping and small computer mouse grasping. Experimental results are shown in Fig. 7 and Fig. 8. The result of the bottle grasping task is displayed in Fig. 7. The robot can grasp the 500 ml plastic bottle immediately after receiving the EMG signals from muscles. The bottle was not damaged during the grasping and also held in the robot hand without slipping. For the computer mouse grasping in Fig. 8, the robotic hand performed the hand closing action to grab the computer mouse after receiving the EMG signals. The computer mouse was also not damaged nor slipped during grasping. Therefore, the proposed robot hand passed the tests.

Despite the initial success in controlling the robot hand to perform the simple tasks, the robotic hand has some notable difficulties during the tests. The first problem is the design of the hand. The robot hand can be seen grasping small objects with difficulties. As seen in Fig. 8(b) and Fig. 8(c), the computer mouse was held by the fingertip of the robotic

hand. Another problem is the robotic hand movements. The robotic hand moves according to the programmed movements and pressure sensors. This can be unfavorable for tasks which require the specific amount of force such as handling extremely fragile objects.

CONCLUSIONS

This paper presented the myoelectric hand developed through 3D printing. The robotic hand is controlled by EMG signals from muscles in the human arm. Each part of the robotic hand was printed from the 3D printer. The main controller is the Arduino MEGA. EMG signals are received from the flexor and extensor muscles located in the human arm. Experimental results showed that the robotic hand can perform simple actions in terms of closing and opening the hand, regarding the EMG signals. The robotic hand was tested initially with two object grasping tasks. Objects in the tests were grabbed and held with the proper force without slipping from the robotic hand. The future works include the improvements of the hand design and further applications with deep learning approaches.

***Abstract*—Antimagic graph labeling is the allotment of positive numbers to the edges of a graph such that the sum of graph edge labels incident to each node varies. The paper emphasizes on strong antimagic graph labeling for splitting graph and shadow graph of cycle. Modified theorems and their proofs on splitting and shadow graphs of cycle have been presented. The validity of the theorems has been illustrated through numerous examples.**

Keywords—antimagic graph, splitting graph, shadow graph, cycle, strong antimagic graph, weak antimagic graph

I. INTRODUCTION

Graph labeling can be defined as placing labels on the edges and nodes of a graph. These labels usually consist of integers. It's a very popular topic for research and many informative papers on different types of graph labeling have been published till now. Antimagic graph labeling is one of such type which was founded by Hartsfield and Ringel in 1990 [4]. This research basically focuses on antimagic graph labeling for splitting graphs and shadow graphs of cycle.

In [1] Vaidya and Vyas have introduced some theorems on antimagic graph labeling of total graph, middle graph, splitting graph and shadow graph of cycle and path. The theorems based on splitting graph and shadow graph of cycle from [1] have been modified in the paper by introducing some functional equations which have been narrated in the following sections with proper illustrations.

All the graphs used in the work are finite, connected, undirected and labeled. Here each graph is represented by G where $|V(G)|$ and $|E(G)|$ are its number of nodes and edges respectively and C_n is the cycle formed by the graph.

In this article Section II holds the literature review. All necessary definitions are stated in Section III. Section IV holds in our work and the outcomes of the work are briefly narrated in Section V. Lastly, Section VI brings a conclusion to the article.

II. LITERATURE ANALYSIS

In 1963 the notion of magic graph labeling was used by Sedlacek in his paper [4].

The theory of antimagic graph labeling was founded by Hartsfield and Ringel, where they verified that paths P_n where $n < 3$, cycles, wheels and complete graphs K_n where $n<3$ are antimagic graph in [3].

In [5] it has been demonstrated that graphs attained by switching of a pendant node in path P_n, switching of a node in the cycle C_n, switching of a rim node in wheel W_n, switching of apex node in helm H_n and switching of a node of degree 2 in fan F_n are antimagic graphs.

In [1] the authors investigated antimagic graph labeling for middle, total, splitting and shadow graphs of path and cycle respectively.

In [2], the authors have presented revised theorems on antimagic labeling for middle and total graph associated with a path that have been introduced in [1].

In [6], Michael Jackanich defined the concepts of strong and weak antimagic graph labeling and showed that any bipartite graph has weak ant-magic labeling.

In [7], C.Meenakshi and KM.Kathiresan have worked on magic and antimagic labeling of graphs and discussed k – magicness of complete bipartite graph $K_{p,p}$ where $1<k<2p$.

In [8] the authors defined degree splitting graph of a graph and studied some properties of it.

In [9], P. Lawrence Rozario Raj, S.Koilraj worked on splitting graphs of cycle C_n, path P_n, complete bipartite graph $K_{m,n}$, matching M_n, wheel W_n and $< K^{(1)}_{l,n} : K^{(2)}_{l,n} : \ldots : K^{(k)}_{l,n} >$ and proved all of them are cordial.

In [11], S. K. Vaidya and R. M. Pandit did analysis on shadow graphs, middle graphs, and total graphs of paths and cycles and determined the edge domination number.

The research mainly features on splitting and shadow graphs of cycle. The theorems introduced in [1] on splitting and shadow graphs of cycle have been improved in this paper with proper illustrations.

III. PRELIMINARIES

A. Antimagic Graph

It is a graph where positive integer values are used for labeling the edges in a manner, where the summation of the edge labels incident to each node varies from one another and its labeling is known as antimagic graph labeling. These graphs can be classified into strong and weak antimagic graph.

The first one is a type, where each edge label is completely different from one another. Such labeling is called strong antimagic graph labeling [2]. On the contrary, the second one

is a type where each edge label is not necessarily different from one another. Such type of labeling is weak antimagic graph labeling [2].

B. Splitting Graph

Splitting graph S'(G) of graph G is such a graph which is constructed in a way where a new node v' is added correlating with each node v of graph G and $N(v) = N(v')$. Here, $N(v)$ and $N(v')$ are the neighborhood sets of v and v' [1].

C. Shadow Graph

Let us first take two copies of a cycle G, say G' and G''. Now if we connect each node v' of G' to the neighbors of the correlating node v'' in G'', the graph that forms is defined as shadow graph $D_2(C_n)$.

D. Cycle

Cycle graph (C_n) having n nodes is a graph which is composed of a single cycle that is, the connected nodes form a closed chain.

IV. Our Work

A. For Splitting Graph

In [1], the authors used two cases, Case 1: $n \equiv 1 \pmod 2$ and Case 2: $n \equiv 0 \pmod 2$ whereas Case 2 contains two sub-cases to prove that splitting graph of cycle C_n is antimagic. But it deprives us from gaining a strong antimagic one as output. So, to gain a strong antimagic graph, we have revised the theorem and come up with a new theorem and evinced it.

Theorem 1.1: **Splitting graph of cycle C_n is antimagic.**

Proof: Let $v_1,v_2,v_3,.....v_n$ represent the nodes and $e_1,e_2,e_3,.....e_n$ the edges of cycle C_n. Let v_1', v_2', v_3',....,v_n' represent the newly added nodes to form the splitting graph of cycle C_n. Let G be $S'(C_n)$, the splitting graph of cycle C_n. $V(S'(C_n))=\{v_i, v_i' / 1 \le i \le n\}$ and $E(S'(C_n)) = \{v_i'v_{i+1};\ 1 \le i \le n-1,\ v_nv_1,\ v_1'v_n,\ v_i'v_{i-1};\ 2 \le i \le n,\ v_iv_{i+1};\ 1 \le i \le n-1,\ v_nv_1\}$. Here $|V(G)| = 2n$ and $|E(G)| = 3n$. To define $f:E(G) \rightarrow \{1,2,3,.....3n\}$ we consider following two cases.

Case 1: $n \equiv 1 \pmod 2$

For $1 \le i \le n-1$:

$f(v_i\ v_{i+1}) = 2n+1+i;$
$f(v_n\ v_1) = 2n;$
$f(v_n'\ v_1) = 2n+1;$

$$f(v_i'v_{i+1}) = \begin{cases} 2i+1, & i \equiv 1 \pmod 2 \\ 2i, & \text{otherwise.} \end{cases}$$

For $2 \le i \le n$:

$$f(v_i'v_{i-1}) = \begin{cases} 2i-1, & i \equiv 1 \pmod 2 \\ 2i-2, & \text{otherwise.} \end{cases}$$

$f(v_1'v_n) = 1;$

Case 2: $n \equiv 0 \pmod 2$

For $1 \le i \le n-1$:

$f(v_i\ v_{i+1}) = 2n+1+i;$
$f(v_n\ v_1) = 3n + 1;$
$f(v_n'\ v_1) = 2n;$

Sub Case 1: $n \equiv 0 \pmod 4$

$f(v_2'\ v_1) = 4;$
$f(v_2'\ v_3) = 2;$
$f(v_1'\ v_n) = 1;$

For $1 \le i \le n-1$, $(i \ne 2)$:

$$f(v_i'\ v_{i+1}) = \begin{cases} 2i+1, & i \equiv 1 \pmod 2 \\ 2i, & \text{otherwise.} \end{cases}$$

For $3 \le i \le n$:

$$f(v_i'\ v_{i-1}) = \begin{cases} 2i-1, & i \equiv 1 \pmod 2 \\ 2i-2, & \text{otherwise.} \end{cases}$$

Sub Case 2: $n \equiv 1 \pmod 4$

$f(v_1'\ v_n) = 3;$
$f(v_1'\ v_2) = 1;$

For $2 \le i \le n$:

$$f(v_i'\ v_{i+1}) = \begin{cases} 2i+1, & i \equiv 1 \pmod 2 \\ 2i, & \text{otherwise.} \end{cases}$$

$$f(v_i'\ v_{i-1}) = \begin{cases} 2i-1, & i \equiv 1 \pmod 2 \\ 2i-2, & \text{otherwise.} \end{cases}$$

These portrayed edge labeling functions will lead to all the distinct node labels fulfilling the state for antimagic labeling. Consequently, $S'(C_n)$ is antimagic.

Analogy 1.1 The theorem is illustrated through some examples. Splitting graph of cycle C_4 is antimagically labeled in Figure 1. C_4 has four nodes and four edges. So, its splitting graph has eight nodes and twelve edges. According to our proof, Sub-Case 2 of Case 2 is relevant for $n=4$ and implementation is done accordingly.

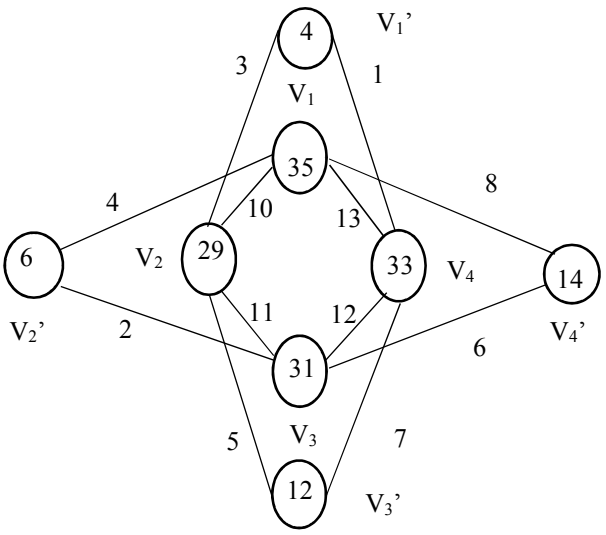

Fig. 1. Antimagically labeled splitting graph of cycle C_4.

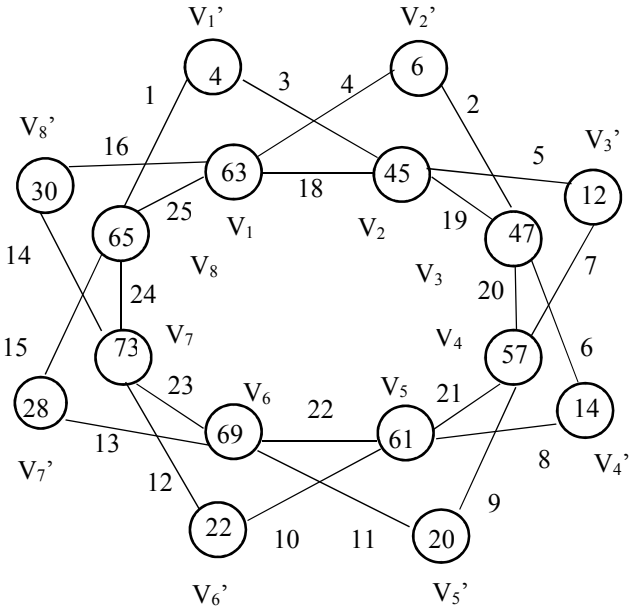

Fig. 2. Antimagically labeled splitting graph of cycle C_8.

Figure 2 displays us antimagically labeled splitting graph of cycle C_8. C_8 has eight nodes and eight edges. So, its splitting graph has sixteen nodes and twenty-four edges. According to our proof, Sub-Case 2 of Case 2 is relevant for $n=8$ and implementation is done accordingly.

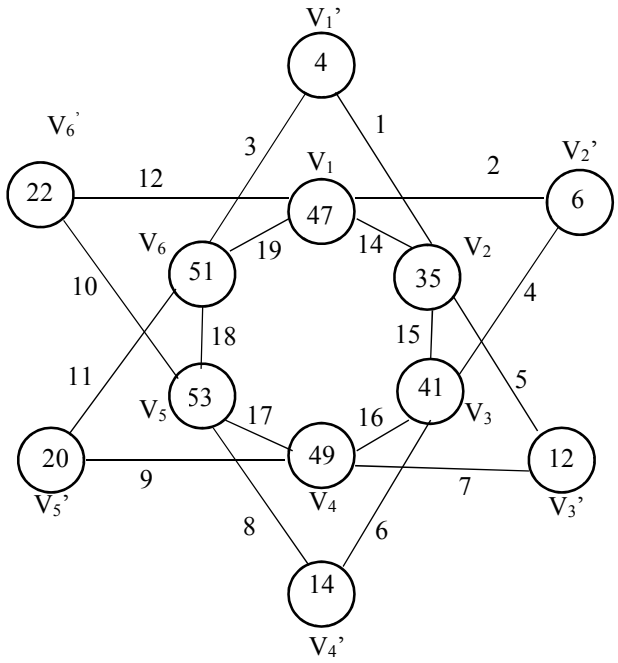

Fig. 3. Antimagically labeled splitting graph of cycle C_6.

Figure 3 displays us, antimagically labeled splitting graph of cycle C_6. C_6 has six nodes and six edges. So, its splitting graph consists of twelve nodes and eighteen edges. According to our proof, Sub-Case 1 of Case 2 is relevant for n=6 and implementation is done accordingly.

B. For Shadow Graph

In [1], the authors used three cases, Case 1: $n \equiv 1 \pmod 2$, Case 2: $n \equiv 0 \pmod 2$, $n \neq 6$ and Case 3 to demonstrate that shadow graph of cycle C_n is antimagic, which doesn't give a strong antimagic graph as an output. So, to gain a strong antimagic graph, we have revised the theorem and come up with a new theorem and evinced it.

Theorem 1.2: **Shadow graph of cycle C_n is antimagic.**

Proof: Let C'_n ,C''_n be two copies of cycle C_n . We indicate the nodes of first copy of C_n by $v_1', v_2', v_3', \ldots, v_n'$ and second copy by $v_1'', v_2'', v_3'', \ldots, v_n''$. Let G be $D_2(C_n)$ with $|V(G)|=2n$ and $|E(G)| = 4n$. In order to define $f:E(G)\rightarrow\{1,2,3,\ldots..4n\}$ the two cases given below have been considered.

Case 1: $n \equiv 1 \pmod 2$

For $1 \leq i \leq n-1$:

$f(v_1'' v_{i+1}'') = i;$

$f(v_n'' v_1'') = n;$

$f(v_i' v_{i+1}') = 3n + i;$

$f(v_n' v_1') = 4n;$

$f(v_i'' v_{i+1}') = n + 2i - 1;$

$f(v_n'' v_1') = 3n - 1;$

$f(v_i' v_{i+1}'') = n + 2i;$

$f(v_n' v_1'') = 3n;$

Case 2: $n \equiv 0 \pmod 2$,

$f(v_n'' v_1'') = 1;$

$f(v_n' v_1') = 4n;$

$f(v_n' v_1'') = n + 1;$

$f(v_1' v_n'') = n + 2;$

For $1 \leq i \leq n-1$:

$f(v_i'' v_{i+1}'') = 3n + i;$

$f(v_i' v_{i+1}'') = n + 1 + 2i;$

$f(v_i' v_{i+1}') = i + 1;$

For $2 \leq i \leq n$:

$f(v_i' v_{i-1}'') = n + 2i;$

These portrayed edge labeling functions will lead to all the distinct vertex labels satisfying the state for antimagic labeling. Consequently, $D_2(C_n)$ is antimagic.

Analogy 1.2 The theorem is illustrated through some examples. Figure 4 displays us, antimagically labeled shadow graph of cycle C_5. C_5 has five nodes and five edges. So, its shadow graph has ten nodes and twenty edges. According to our proof, Case 1 is relevant for $n=5$ and implementation is done accordingly.

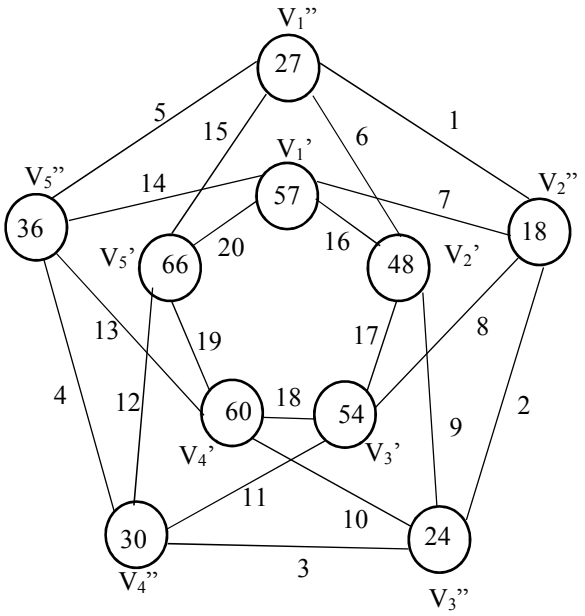

Fig. 4. Antimagically labeled shadow graph of cycle C_5.

Shadow graph of cycle C_6 is antimagically labeled in Figure 5. C_6 has six nodes and six edges. So, its shadow graph consists of twelve nodes and twenty-four edges. According to our proof, Case 2 is relevant for *n=6* and implementation is done accordingly.

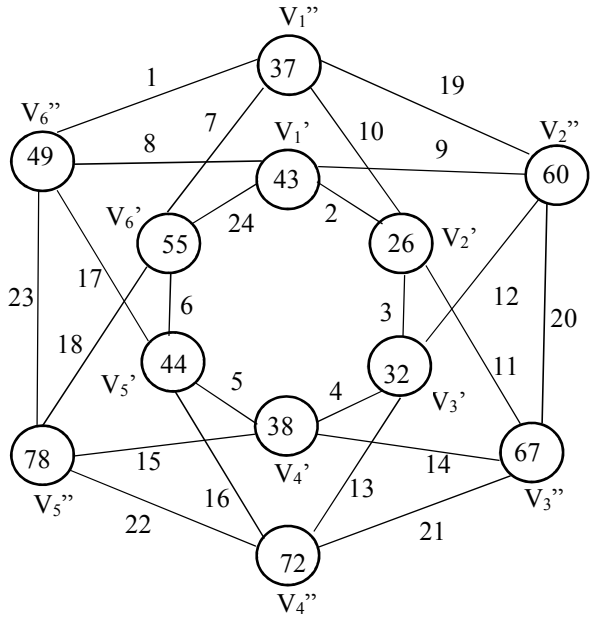

Fig. 5. Antimagically labeled shadow graph of cycle C_6.

Figure 6 displays us antimagically labeled shadow graph of cycle C_8. C_8 has eight nodes and eight edges. So, its shadow graph has sixteen nodes and thirty-two edges. According to our proof, Case 2 is relevant for *n=8* and implementation is done accordingly.

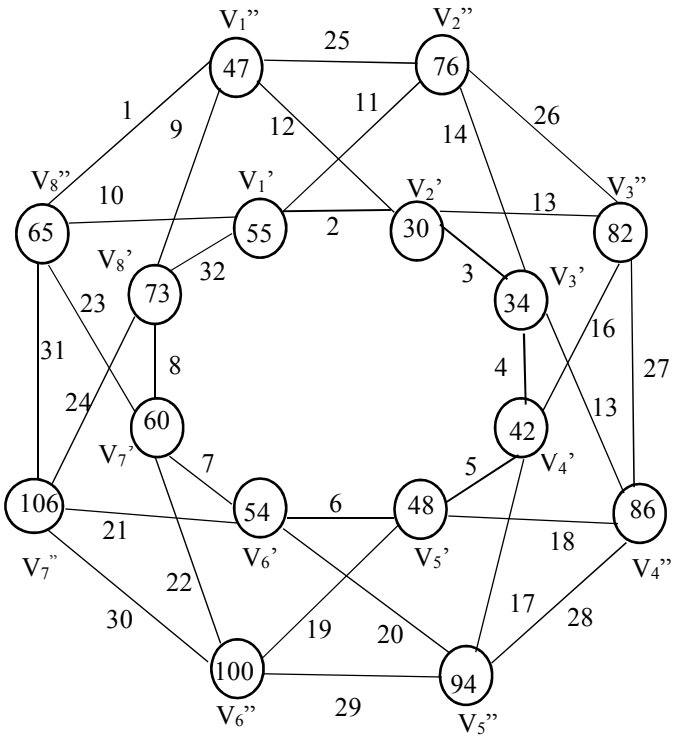

Fig. 6. Antimagically labeled shadow graph of cycle C_8.

V. RESULTS

A. For Splitting Graph

We improved the validation of the theorem which is unlike the one conveyed in [1].

In [1], the authors demonstrated two cases, Case 1: $n \equiv 1 \pmod 2$ and Case 2: $n \equiv 0 \pmod 2$ whereas, Case 2 consists of two sub-cases, Sub Case 1: $n \equiv 0 \pmod 4$, $n \neq 4$ and Sub Case 2: $n = 4, n \equiv 1 \pmod 4$. After implementing the theorem, we saw that Case 1 works perfectly providing a strong antimagic graph as an output. But, by using the edge label equations of Case 2, we don't achieve a strong antimagic graph, in fact, there remain some nodes with no values.

According to the equations of [1], when we used $f(v_n v_1) = 3n$, then we got a weak antimagic graph as an output. For instance, when $n=6$, we got value 18 for both v_6v_1 and v_5v_6 edges which made the graph weak.

For solving this problem, we used the function equation $f(v_n v_1) = 3n + 1$. When we applied this, we got a strong antimagic graph. Suppose, when $n=6$, we got value 19 and 18 for v_6v_1 and v_5v_6 edges which made the graph a strong antimagic.

In Case 2 provided in [1], there was no equation for $f(v_n' v_1)$. So, there was no way to get any value for the edge $v_n' v_1$. As a result, we couldn't get any value for nodes v_n' and v_1. Hence, it couldn't lead to any complete antimagic graph.

In order to resolve this issue, we provided $f(v_n' v_1) = 2n$. As a result, we got the value for the edge $v_n'v_1$ as well as the values of v_n' and v_1 nodes. All these can lead to a strong antimagic graph.

In Sub-case 1 of [1], when we used the condition, $1 \leq i \leq n, (i \neq 2)$ then we got an extra vertex and an extra unnecessary edge. For instance, when, $n=8$, we got an extra vertex v_9 and an extra edge $v_8'v_9$ whereas none of these exist in the graph.

For solving this issue, we used the condition, $1 \leq i \leq n - 1, (i \neq 2)$. Hence, we got rid of getting any extra and unnecessary vertex and edge which didn't exist in the graph.

Also, according to [1], Sub-case 1 was applicable for $n \equiv 0$ (mod 4) but not for $n=4$, Sub-case 2 was applicable for $n \equiv 1$ (mod 4) and $n=4$. But, after all the modification has been done to the theorem, Sub-case 1 worked for $n \equiv 0$ (mod 4) as well as $n=4$. The corrected implementation is provided in Figure 1.

B. For Shadow Graph

The proof of the theorem has been improved such that it differs from the proof provided on [1].

In [1], $f(v_i'v_{i-1}'')=n+2i$ was included in Case 1. But if that function equation was used then we would get values for some edges double times. Also, there was no function equation provided for $v_i'v_{i-1}''$. For example, when $n=5$, using $f(v_i'v_{i-1}'')=n+2i$, we would get double values for the edges $v_2'v_1''$, $v_3'v_2''$, $v_4'v_3''$ as there was another function equation given, which provided values for those same edges, whereas we couldn't get any value for the edges $v_1'v_2''$, $v_2'v_3''$, $v_3'v_4''$, $v_4'v_5''$.

For solving this problem we provided $f(v_i'v_{i+1}'')=n+2i$. It helped to find the values for the edges $v_i'v_{i-1}''$ and so, there was no more double values for $v_i'v_{i+1}''$.

In [1], the authors have given $f(v_1'v_n'')=3n$ for Case 2. But using this function equation, it would result into a weak antimagic graph. For instance, for $n=8$, we got the value 24 for both $v_1'v_8''$ and $v_8'v_7''$ which lead us to a weak antimagic graph.

In order to resolve this issue, we provided $f(v_1'v_n'') = n+2$. Using that, we obtained a strong antimagic graph. For instance, for $n=8$, we got the value 10 and 24 for $v_1'v_8''$ and $v_8'v_7''$ respectively which lead us to a strong antimagic graph.

Vaidya and Vyas showed Case 3 whereas there was no function equation to find the values for the edges of the graph in [1] and that Case 2 was not applicable for n=6. But, the modification that we provided didn't require any Case 3 and that Case 2 supported $n=6$. The corrected implementation is provided in Figure 5.

VI. CONCLUSION

We have appraised the antimagic labeling for splitting and shadow graph of cycle. The result and the examples reveal that our modification of the theorem provided in [1] produces better performance than those explained in [1]. We have presented the proofs of the theorem along with some examples in section IV and in section V we have unfolded the scope of improvements found in [1] and elaborately discussed our solution that we figured out. Magic and antimagic labeling are feasible for many more graphs and there is a huge scope to adopt further researches in this sector.

***Abstract*— A major population of 3rd world countries have problems reading out texts because of the low literacy rate. While smartphones have given them a hope to lead a better life, interacting with them needs a certain level of literacy which a majority of them lack. Given the rapid growth of variation in this user base, it is evident that interactive graphical representations can give a better understanding of contents especially to the children and to the illiterate people. This work emphasizes on making the Google play app store more usable as this is the most used app for smartphone users. In this study, new icons have been designed and then compared side by side with 16 existing Google play app category icons to initially find out the legitimacy of the new icons. Further, a survey between smartphone users has been conducted and the results show that the new icons fare better while representing app categories. Based on the survey results and more widely accepted icons, some key factors to design icons have been identified.**

Keywords—Human Computer Interaction, Graphical Representation, Icons.

I. INTRODUCTION

The technological improvement in the field of mobile devices is a landmark of this decade. A smartphone is one of its significant achievement with a more powerful package than its predecessors. According to Statista [1], over 2.53 billion people have used a smartphone up to the year 2018. Statistical information suggested that this number will increase up to 2.87 billion by this year 2020. As the smartphone is reaching to more people, it is a challenging job to maintain a smart interface which can be easily understandable for its massive user groups.

Another survey of Statista states that, the Google Play store currently has a total of around 2.1 million applications while the Apple store has around 2 million applications [2]. Dividing or labeling these large number of apps in different categories or genres are used to help people browsing applications, finding what they need and what they can expect from a particular application. If considered different domains of mobile applications, merely 50 categories can be found at most in any app store. These categories are described by using textual labels such as, for example, "Education" or "Lifestyle" on the Google Play store. However, this kind of representation may not be suitable for people who do not know how to read or still developing reading skills such as children. Although there is some graphical representation associated with the text labels, those are not user-friendly. People often find it difficult to reach the app they wanted [3] [4]. To facilitate these user groups, work has been done in this study towards text free smart interface where icons can solely describe a particular application category.

Text is always the best way to interact with a system [5], but sometimes they are less effective when the person or user is not very familiar with the language. Graphical representation is the best possible alternative of this problem. In order provide a better understanding through graphical representations, new icons were designed and put alongside with the existing icons. Then people were asked to tell which icons they prefer most, and a total of 664 responses were collected. It was found that the people participating in the surveys were able to understand the new set of icons with accuracies over 80% of times for most of the categories. The result of this survey suggests that the existing icon sets are confusing and misleading people every time and using a new set of icons can better describe an application category which will improve their content searching experience and increase the usability of app stores for more users. Finally selection and analysis have been conducted for identifying the characteristics of more widely accepted icons.

II. RELATED WORK

Human-computer interaction is a very significant field of research as it investigates the way humans interact with computer or computerized machines to ensure better acceptability and convenience [6]. While human refers to people of every age, several fragments have been introduced in order to differentiate and specify works for different age groups. A very specific study on games category icons design has been done where different sets of icons were designed for different mobile gaming categories to investigate if kids can distinguish them as specific categories [7]. This particular study emphasizes on whether children can understand the type of a game solely using icons. This is a very narrow domain and does not cover a significant part of the smartphone users. However, it shows that children and adults differ cognitively and physically, as a result different technology and interaction techniques need to be developed for them [8]. While working for different age groups, it's very important to look at their different types of requirements and behavior [9]. Users' preferences and time to needed to process information from the icons were analyzed to determine the aesthetic appeal of different types of icons from different design eras in [10]. This study goes very theoretical with the time factor and also the preference. However, the objective of developing a set of icons that can be identified without the help of any kind of text

has not been achieved here. In [11], 315 icons were developed for 45 functions specifically for smart building. This work is also a very domain specific which in this case is smart buildings. There has not been much work in terms of designing icons for the mass people especially on a platform like the Google play store which is used by all the smartphone users all over the world.

There has been some studies where the factors of designing icons has been discussed. In [12], six influencing factors were found out regarding aesthetic designs of icons. Although it defines a way of designing aesthetically pleasing icons, a proper analysis has always been demandable. In this study, an analysis has been done from the results obtained from the human survey for newly designing icons by comparing with the existing ones from Google play store keeping the design interaction in mind.

III. App store category selection

In the Google play store, there are more than 35 app categories to choose from. The list of categories have a specific icon beside the category name to represent the category graphically. Primarily during the feasibility study of this research work, a public survey was conducted to know the opinion of users about these category defining icons. From the survey, it became evident that the current icons are very much abstract and do not exactly represent the whole idea of the category. Hence, designing better icons for representing app categories became a viable research goal. Also, every category icon is not poorly designed, so categories were chosen having more useful and widely used apps. Primarily to start the investigation, 16 different app categories were chosen. They are Arts & Design, Beauty, Business, Communication, Entertainment, Finance, Health & Fitness, Lifestyle, Maps & Navigation, News & Magazines, Personalization, Photography, Social, Sports, Travel & Local and, Weather. The primary goal of the study was to design new graphical representations (icons) for these 16 categories. The categories along with their definition is given in the table 1 which can help understand the type of apps that are under a specific category.

IV. Icons and User Survey

A. Icons Design

The primary objective of this study is to design better icons for better graphical representation and furthermore, analyze the icon adaptation behavior of user to understand specifics about the likes and dislikes. The app category icons were tried to be designed in a way which would be more understandable for illiterate, older adults and children with special focus on making them understandable without any help from text. It has been always kept in concern to design fair icons, representing them with real world objects as people can relate to them more easily. The table 2 represents the investigated icons which are kept side by side in order to find the actual icons.

B. Survey Design

After the icons for the 16 selected categories are designed, a survey was conducted among smartphone users to determine if the newly designed icons are any better than the existing ones from the Google play store. A Google form was designed for this purpose. For each category, both icons (1 new and 1 existing from Google play store) were kept side by side and the users were asked to choose the icon that represents that category better.

It was made sure that the participants of the survey were all smartphone users. Also, efforts were made to introduce varieties of users to get a more diversified result. To facilitate this, three extra parameters were introduced such as gender, occupation, and age. Total 664 responses collected from the

TABLE 1: SELECTED APP CATEGORIES AND DEFINITIONS

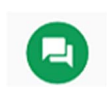
Category	Definition
Art & Design	Applications to create designs combination of text, colors, and pictures.
Beauty	Image-based makeup guidelines, makeover tools, and simulation applications.
Business	Applications having the functionality of editing or reading documents, tracking of packages, email management, and job searching.
Communication	Applications that help to engage people, share and communicate with each other.
Entertainment	Streaming TV shows, movies, music and many more.
Finance	Applications that help to manage banking, payment, taxes, fetching financial news and done complex financial calculations.
Health & Fitness	Exercise tracking, health & nutrition information, safety tips.
Lifestyle	Applications to guide your style, plan your wedding & party.
Map & Navigation	Applications that can help you to reach your desired locations.
News & Magazines	Blogging applications, newspapers, magazines.
Personalization	Applications that help to decorate your devices wallpapers and ringtones, alarm tones etc.
Photography	Taking photographs, editing, and sharing applications.
Social	Apps to socialize contents.
Sports	Sports coverage, commentary, scores, and news.
Travel & Local	Application to manage your tour, information about places you must visit, city guides etc.
Weather	Weather report and news applications.

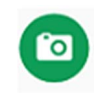
participants of the different professions where the majority of them were students. About 513 (77.3%) participants were male while the rest 151 (24.7%) were female. Above 90% of the applicants were students while the others were either job holders or self-employed. According to our data, 81.3% participants were between the age of 21 and 25 as they are university students. 10.1% of them were aged between 16 and 20 while there were participants from age groups 26 to 30, 31 to 35 and, more than 36.
After receiving an adequate number of responses, they were carefully evaluated. The evaluation criteria is simple as all the questions were closed and could only take 2 responses.

V. Results Analysis

From the 664 responses that were recorded via the online survey, a very good idea can be obtained whether the newly designed icons represent better values or not. As mentioned earlier, there were only 2 options, one being the newly designed icons and the other being the existing category icons from Google play store. The Fig. 1 shows the overall survey result on the whole. It shows all the 16 chosen categories along with the acceptance percentages of both set of icons for them.

As there have been only 2 options for the users to choose from, the results percentages from new icons and existing icons add up to the full results. The newly designed icon for "Art and Design" was preferred by 88% participants while the existing one was preferred by the rest 12%. The new "Beauty" icon was preferred by 93.4% participants while the "Business" icon was preferred by 90.8% participants compared to the 6.6% and 9.2% for existing icons respectively. New icons for "Communication", "Entertainment" and "Finance" were preferred by 84.3%, 95.5%, and 95.9% participants respectively. New "Health and Fitness" icon was preferred by 82.1% participants while the new "Lifestyle" icon was preferred by 93.1% participants. The new icon for "Maps and Navigation" was preferred by 92.8% participants and the new "News and Magazines" icon was preferred by 82.4% participants.





There were some newly designed icons that received mixed responses and have been challenging to make people understand by a small piece of art. Among these type of categories, "Personalization" was preferred by 64.8% participants, "Photography" was preferred by 78.3% participants and "Social" was preferred by 71.2% participants. There were some other icons like "Sports" which was preferred by 82.7% participants while newly designed "Travel and Local" and "Weather" were preferred by 72% and 91.1% participants respectively.

According to the result, most people have preferred the newly designed icons to the existing ones except from a couple of categories like personalization. This happened because of the abstractness of the category as it cannot be represented by a specific object.

VI. Challenges And Discussion

At the phase of designing the new icons there have been several challenges. As example, designing the icon for the category "Beauty", there was a dispute whether it should be represented by beauty products or anything else. Another challenging scenario was the icon of "Lifestyle" as it cannot be represented by a specific object, so summing a daily life picture in a single icon is very difficult. In the end a suitable

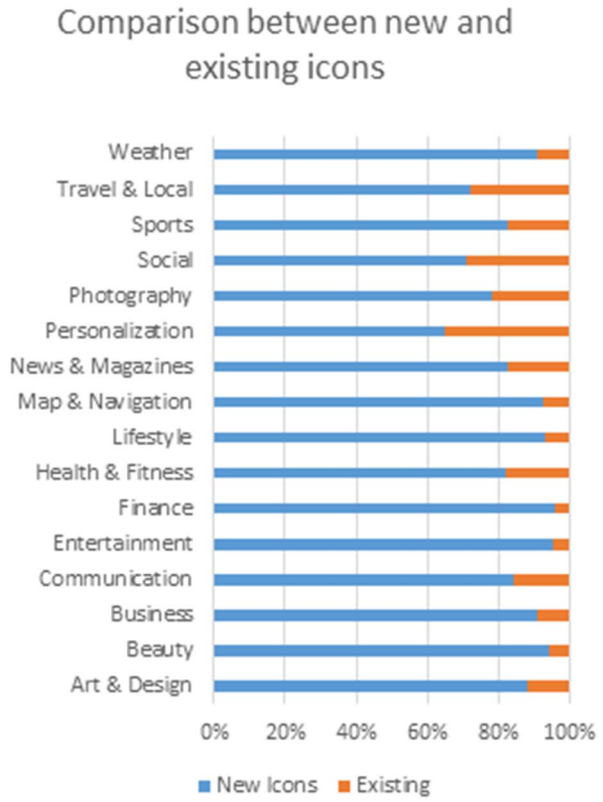

Fig. 1: Analysis of results obtained from the survey

icon was designed but when seen in a smaller format, it might seem too crowded. While designing an icon, the primary approach taken was representing the category by objects belonging to them. Such as the "Sports" icon has been designed by combining three of the most popular sports equipment.

The icons of "Finance" and "Business" were also very challenging as these categories are quite similar and related to each other. Similarly, "Communication" and "Social" were also challenging because of their connections with each other. From the fact of preference given to icons by users, specific points can be noted by analyzing them to find out the actual components of a successfully designed icon. As example, the "Arts and design" logo is represented by a pallet and brushes while the existing one only shows a pallet. Adding the brushes made the pallet more obvious and made a great difference. For beauty, the existing icon is a shape of hairdryer which does not nearly represents beauty.

For the new icon, beauty is represented by a beautiful face. The "Business" icon is represented by two figures of human and a money sign as business means deals between people. "Entertainment" has been represented by a couple of forms of entertainment like video and audio both which makes it easier to understand. The most challenging icon to design has been "Lifestyle" and "Personalization" as these are very abstract ideas. However the main components of people's daily lives have been cramped into one icon to represent "Lifestyle" while not much change could be done to the "Personalization" icon resulting in lower preference rate.

While designing the new icons, the main focus was to represent a specific idea using the objects or components that comes to mind specifically for the categories. It was evident from the results that users of smartphones prefer icons that have relevant objects in them relating to the category. While this is an encouraging start, there are still so much to do. This study has been conducted with a portion of the categories in Google play store. A store wide study can be done for more accurate and diversified result. Another shortcoming of this work is that the survey population is mostly young smartphone users. More thorough survey covering users from different age groups can create a dimension of results.

VII. Conclusion

Today people are using a smartphone beyond the boundary of languages and cultures, they often belong to different age groups, and they have a different level of education or might even be illiterate. This study aims to promote the use of designing interfaces based on graphical representations such as icons which could be the first step towards text free interfaces in mobile industry. The newly designed icons for app categories in Google play store have been appreciated by most users who have completed the survey comparing both sets of icons. Overall, this study is very encouraging for future works keeping text free interfaces in mind. Further extension of this work can be done in a larger scale to graphically represent not only icons but everything in a smartphone.

Abstract— **Data compression is the way toward modifying, encoding or changing over the bit structure of data in such a way that it expends less space. Character encoding is somewhat related to data compression which represents a character by some sort of encoding framework. Encoding is the way toward putting a succession of characters into a specific arrangement for effective transmission or capacity. Compression of data covers a giant domain of employments including information correspondence, information storing and database development. In this paper we propose an efficient and new compression algorithm for large natural datasets where any characters is encoded by 5 bits called 5-Bit Compression (5BC). The algorithm manages an encoding procedure by 5 bits for any characters in English and Bangla using table look up. The look up table is constructed by using Zipf distribution. The Zipf distribution is a discrete distribution of commonly used characters in different languages. 8 bit characters are converted to 5 bits by parting the characters into 7 sets and utilizing them in a solitary table. The character's location is then used uniquely encoding by 5 bits. The text can be compressed by 5BC is more than 60% of the actual text. The algorithm for decompression to recover the original data is depicted also. After the output string of 5BC is produced, LZW and Huffman techniques further compress the output string. Optimistic performance is demonstrated by our experimental result.**

Keywords— ***encoding; compression; decompression; 5-bit compression; compression ratio.***

I. INTRODUCTION

Data compression is broadly used and imperative issue in information science applications because of capacity limit and exchange speed of different systems [1][2]. There are undeniable advantages which may be accomplished incorporates diminishing capacity necessity and data transmission, encoding littler bit numbers, short time essential for broadcasting, powerful channel utilization etc. [3][5]. Having a decent packed scheme conspire remapping any text by shorter bit is vital [1][2][5]. So a new system of encoding can be important representing to a source of data precisely conceivable utilizing least bit numbers putting the actual meaning unaltered [1][2][11]. In many cases, to reestablish data into the original organization because of the compacted structure is vital [6]. Zipf distribution is used in this paper to construct the dictionary of characters. It actually came from Zipf's law. Zipf's law can be said to an experimental law formulated utilizing mathematical statistics that alludes to the way that numerous sorts of data studied in the physical and social sciences can be approximated with a Zipf distribution. Zipf's law expresses that given some corpus of natural language utterances, the frequency of any word is conversely corresponding to its position in the frequency table [4]. In this way the most frequent word will happen approximately twice as regularly as the second most frequent word, three times as regularly as the third most frequent word. The compression techniques of data are ordered extensively as lossy and lossless [8]. Lossy technique comprises towards a change to imperative against immaterial data, trailed by compression of lossless data in the essential case and disposing rest of the data. As a matter of fact, Lossy technique functions by decreasing amount of document by reducing superfluous text or data [1][11]. The 5BC algorithm which we proposed is lossless [1][2][8]. The technique deals with the mapping of both forward and backward. 5BC alters characters from 8 bit to 5 bits by parting the characters into 7 sets and utilizing them in a solitary table. By using Zipf distribution, the characters in the table i.e. dictionary are mapping [4][12]. Same characters in the corresponding set code are kept together since it produces shorter sequence of bit code. The 5BC can be able to compress data by more than 60% of the actual data. 5BC compression technique is a logical scheme that shows promising efficiency.

II. RELATED WORKS

The Huffman technique is supposed to be a lossless technique which relies on entropy [9]. It actually construct some binary trees so the codes can be found from the binary tree sequence. Huffman algorithm is said to be the variable length encoding as it mainly works with length of the variable. In the contrary, our 5BC algorithm constantly settled to work with 5 bits as it were. The rule used in this technique is utilizing progressively visit each data via a shorter amount of bits for encoding. In the records of JPEG, Huffman technique is used. JPEG 2000 (JP2) is supposed to be an image compression standard and coding system [13]. Static Huffman and Adaptive Huffman

are the classification of Huffman algorithm [9]. Static Huffman ascertain frequencies right off bat and afterward they create some typical tree for the forward and backward mapping [9][15] though Adaptive Huffman functions by building up trees by figuring frequencies thus constructs two trees in both of these running processes [14]. There exists some compression techniques which are based on dictionaries rather than factual organizations [13][15]. A well-known dictionary based technique is Lempel-Zev Welch or LZW technique [9]. In this algorithm, an individual string αK is constructed by a string α including a K which can be found through the dictionaries. α is additionally added into the dictionary [10]. At the end, the character of string has additionally supplanted again [5]. The existing dictionary functions in form of dynamic information thus it doesn't show to be static [10]. This crude dictionary can be recuperated through the decompressed information at the time of disentangling it. The LZW dictionary can be precisely worked amid the definite specific during Compression and decompression, and disposed of in the wake of packing or process of decompressing has been ended [10]. There is another technique named LZ Technique [5][13] which is additionally popular because of it's straightforwardness as well as It has effective compression proportions. Our technique utilizes a table look up which remains a static one and it will not change during the arrival of new data. The look up table i.e. the dictionary remains fixed and can be utilized for the purpose of compression and decompression as time required.

III. EFFICIENT COMPRESSION SCHEME FOR LARGE NATURAL TEXT

Generally, for the purpose of encoding a character in a memory, 8 bit space in a memory is required [1][2]. We introduce a character encoding scheme of 5 bit called 5BC representing a character via 5 bits in lieu of 8 bits. The algorithm works with all the general printable characters covering both English and Bangla characters that has in normal keyboard. A lookup table is built for representing the Characters by 5 bit. The table is illustrated in TABLE I.

Using 5 bit it can be $2^5 = 32$ combination possible. Among the 32 combinations 25 combinations are used for compression and the rest of the 7 are used for set representation. The character sets are splitted within the number of 7 sets. In the lookup table,

- Bangla characters are placed in Set1, Set2, Set3
- English characters are placed in Set4, Set5, Set6 & Set7
- 7 binary combination are taken for the 7 set.

The Unicode takes 16 bit of memory for representing the natural language character set. This modified 5 bit characters will be converted to 16 bit Unicode characters.

Input: Normal string S,

Output: An encoded compressed string Sc

1: By adding set change,

2: Representing the string S by S`

3: By using the lookup table,

4: Representing the string S` by its corresponding 5 bits representation.

5: The representative string S' contain K bits.

6: **if** K%16=0 **then**
7: jump into end
8: **end if**
9: **else if** K%16!=0 **then**
10: Sum up m bits in the formation of the last 5 bit set code by taking every bit of the set
11: Code one by one and increasing in the same way until (K+m)%16=0
12: **end else if**
13: Represent the 16 bits from (K+m)/K to,
14: Compress string Sc by applying corresponding Unicode text.

Example 1:

Original Text (Input):

I am Bangladeshi

Set Representation: Set4 I Set5 space am space Set4 B Set5 angladeshi

Decimal Representation: 28 8 29 0 2 14 0 28 1 29 2 15 8 13 2 5 6 20 9 10

5 bit representation: 11100 01000 11101 00000 00010 01110 00000 11100 00001 …..…

16 Bit representation: 1110001000111010 0000000100111000 ……

Compressed String: □腱・舭Ш𝔦廷

Algorithm 2: Backward Mapping

Input: Compressed String Sc

Output: An encoded compressed string Sc

1: Representing the string Sc according to it's corresponding 16 bits value of binary number from the Unicode table.
2: Let, Sc contain K bits.
3: For determining 5 bit representation,
4: At first find $K' = int\ (K/5) * 5$.
5: Store the 1st set code of K' in C.
6: Take every 5 bit set code of the K' bit and compare it with C.
7: **if** C is not repeated **then**
8: which means there is an occurrence of set change so C is updated with the new 5 bit set code and
9: compare this new C with the next set code, When C is repeated, the next bit stream will be Cropped
10: Including the bit code of the repeated C.
11: **end if**
12: From the remaining Kth bits stream, taking 5 bits and representing it according to the set of characters in the lookup table.
13: After excluding the number of set, the actual string can be generated.

Example 2:

Compressed String: ・腱・舭Ш𝔦廷

16 Bit representation:

・--- 1110001000111010

腱 --- 0000000100111000

After dividing it by 16

The 5 bit Representation:

11100 --- 28 --- Set4

01000 --- 8 --- I

11101 --- 29 --- space

00000--- 0 ---- Set5 ……..

Decompressed String:

Set4 I Set5 space am space Set4 B Set5 angladeshi

Original Text: I am Bangladeshi

IV. ANALYTICAL ANALYSIS

In 5BC, each characters of 8 bits are represented via 5 bits hence 3 bits are saved. So the probable efficiency of 5BC is (8-5)/8= 37.5%. But after compressing it with Unicode scheme the best efficiency would be more than 60%.

We tried to develop a theoretical analysis to calculate the efficiency precisely. The parameters which are considered for analytical analysis are shown in following table.

TABLE II. PARAMETERS FOR ANALYTICAL EVALUATION

Parameter	Description
I	Original data
E	Encoded data
Ls	Length of the set
Li	Length of I
Ld	Length of E; $Ld = Li + Ls$
T	Total bytes for I
Te	Total bytes for E
η	Efficiency(Te/T)

Let Input data I has length Li. After encoding it becomes E and length become Ld

Where $Ld = L\,i + Ls$

Total bytes for I, $T = Li \times 8$

Total bytes for E, $Te = Ld \times 5$

$$= (Li + Ls) \times 5$$

$$Compression\ ratio = \frac{Compressed\ size}{Uncompressed\ size}$$

$$\eta = \frac{Te}{T}$$

$$= \frac{(Ld \times 5)}{(Li \times 8)}$$

$$= \frac{(Li + Ls) \times 5}{(Li \times 8)}$$

$$= \frac{(5Li + 5Ls)}{(Li \times 8)}$$

$$= \frac{5Li}{(Li \times 8)} + \frac{5Ls}{(Li \times 8)}$$

$$= \frac{5}{8} + \frac{5Ls}{(Li \times 8)}$$

$$= 0.625 + \frac{5Ls}{(Li \times 8)}$$

For usable compression, $\eta \leq 1$ then

$$=> 0.625 + \frac{5Ls}{(Li \times 8)} \leq 1$$

$$=> \frac{5Ls}{(Li \times 8)} \leq (1 - 0.625)$$

$$=> \frac{5Ls}{(Li \times 8)} \leq 0.375$$

$$=> 5Ls \leq (0.375 \times 8) \times Li$$

$$=> Ls \leq \frac{(0.375 \times 8) \times Li}{5}$$

$$=> \frac{Ls}{Li} \leq \frac{(0.375 \times 8)}{5}$$

$$\therefore \frac{Ls}{Li} \leq \frac{3}{5}$$

It is actually the proportion between the set length and original length. It demonstrates that this technique is properly usable until the length of set remains equal or less than 3/5th of the actual data length. And if so then we will get a positive efficiency. But if the ratio is greater than 3/5th the efficiency would be negative.

V. EXPERIMENTAL RESULT

Since 5BC produces a large Unicode string in a printable format. It can be further compressed after applying them in LZW and Huffman. We actually experiment 5 algorithms namely, 5BC, LZW, Huffman, 5BC+LZW and 5BC+Huffman. The experimental result shows the comparison between this 5 algorithms. We have done 3 kind of test comprising the Compression of files, Compression ratio and Compression time.

Compression of files: Here we can see the comparison between the compressions sizes achieved after applying the above mentioned compression techniques on the different datasets.

Compression ratio: Here we can see the comparison between the compressions ratios achieved after applying the above mentioned compression techniques on the different datasets

Compression time: Here we can see the comparison between the compressions times achieved after applying the above mentioned compression techniques on the different datasets.

A. Compression of files:

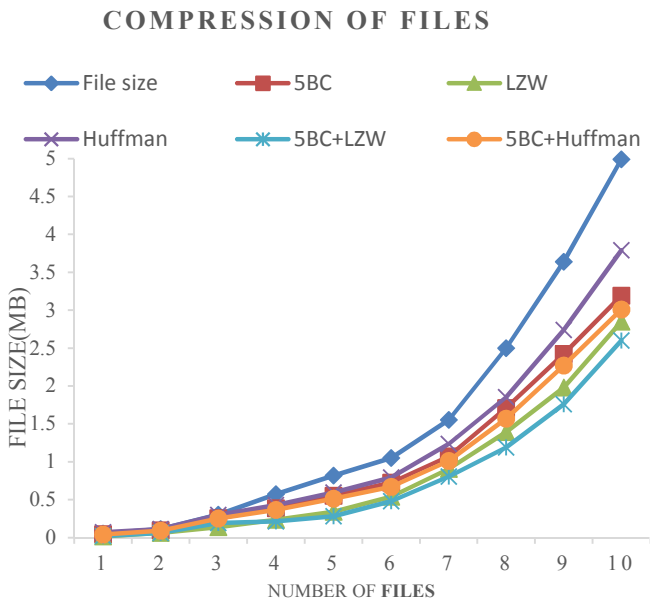

Fig. 1. Compression of file for different data set

From Fig. 1. The result shows that LZW provides the best result in terms of compression of different size file. But our proposed 5BC algorithm also provides very promising result. Our proposed technique performs far better than the well-known Huffman algorithm. And another fact that in terms of increasing data or increasing the file size our technique will converge the compression result of LZW. And if we combine these two techniques with 5BC, both the algorithm 5BC+Huffman as well as 5BC+LZW improves their performance.

B. *Compression Ratio:*

Fig. 2. Demonstrates the compression ratio for different datasets. The result shows that LZW provides very good compression ratio at the initial level when the file size is small but as the size of data is increasing, the efficiency rate will be poor Because LZW provides bad compression ratio for less dictionary size and as the character length increases the dictionary will not easily be made of. So performance reduced. But our proposed idea provides a constant efficiency

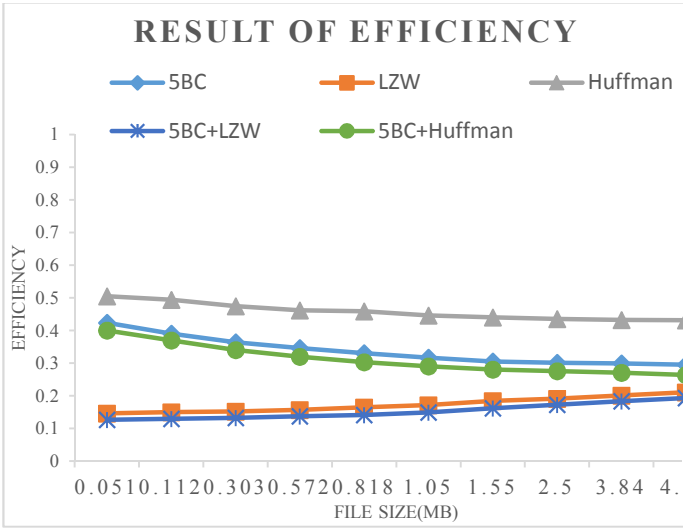

Fig. 2. Compression ratio for different data set

rate at any file size and the performance improves for the increasing number of datasets. It provides a quite better efficiency rate than Huffman. And at some point it will converge the efficiency rate of LZW also. The reason Huffman provides poor efficiency that Huffman technique derives the data from the probability or frequency of occurrence of the possible values in the source symbol [13]. So if the data set is quite large, the frequency generation would be more difficult and a large number of individual symbol will be created. As a result, it provides compression ratio which is average. Another important scenario is that after combining this both algorithm with 5BC, the performance of Huffman will be dramatically improved because this time it works with the compressed data by the 5BC which is much smaller than the original data. The performance of LZW is also improved.

C. *Compression time:*

Figure 3 provides the compression times for different datasets. The result shows that our proposed idea shows average result time when after combining it with LZW and Huffman the performance improves drastically. Though Huffman individually provides the time quite similar with our proposed idea.

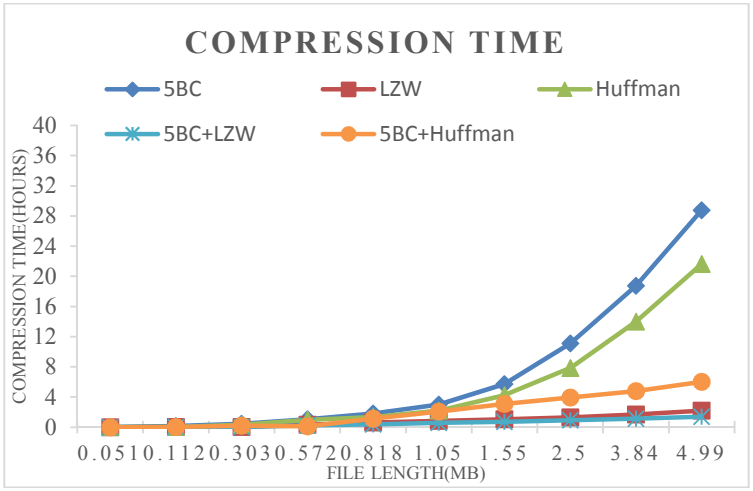

Fig. 3. Compression time for different data set

VI. CONCLUSION

In this research, we try to propose an efficient encoding and decoding technique for data compression which provides a fast and promising performance. This technique is a 5 bit compression scheme and it's character set i.e. dictionary is produced by the Zipf distribution. The proposed technique provides a promising efficiency rate which is more than 60%. This technique can be easily utilized compressing a huge amount of natural datasets. Both the mapping forward and backward make this compression mapping complete as it shows i.e. while decomposing we can achieve the original text. This technique can be implemented in building an innovative and efficient software which can be applied in communication of data, storage of data and database engineering. It can be utilized to parallel processing environment as well as load balancing technique to achieve promising encoding time.

***Abstract*— A structure for $Al_xGa_{1-x}As$/InP multi-junction solar cell is proposed by using numerical simulation and the simulation is done with the help of Analysis of Microelectronic and Photonic Structures (AMPS-1D) simulator. The thickness of p-layer of $Al_xGa_{1-x}As$ top cell is varied from 20 nm to 150 nm keeping the n-layer thickness at a constant value of 800 nm. The thickness of n-layer of InP bottom cell is varied from 100 nm to 7000 nm and p-layer thickness is fixed at 200 nm. The band gap of $Al_xGa_{1-x}As$ top cell absorber layer is varied from 1.42 eV to 1.79 eV. The highest power conversion efficiency (PCE) obtained is 35.643% (V_{oc}=2.385 V, J_{sc} = 15.789 mA/cm^2, FF = 0.88). The operating temperature is also varied from 0 °C to 70 °C. We observed that with the increase in operating temperature, the normalized open circuit voltage decreased almost linearly which shows better stability of this proposed multi-junction solar cell.**

Keywords*— *AlGaAs/InP, AMPS-1D simulation, fill factor (FF), power conversion efficiency (PCE), thermal stability.

I. INTRODUCTION

Solar energy may be used as an alternative source for the rapidly growing demand for energy [1]. As non-renewable sources are becoming scarce day by day, we have to use renewable energy. Fossil fuels like petrol, gasoline, coal etc. emit carbon-di-oxide (CO_2) when they are used. Carbon-di-oxide (CO_2) is one of the major factors of global warming. On the other hand, solar energy creates no pollution to our environment. To make the solar energy useable, a solar cell is needed. Single junction solar cell cannot utilize the photons that have wide-range of solar spectrum ranging from 300 nm to 2500 nm. For example, photons with wavelengths wider than 1100 nm cannot be absorbed by Si solar cell [2]. Addressing the aforementioned drawback of single junction solar cell, researchers have focused on multi-junction solar cell both theoretically and experimentally in the past few decades [3].

A thin-film solar cell is a device fabricated to transform light energy into electrical energy by using the photovoltaic effect. Thin film solar cells which are consisted of polycrystalline materials have better efficiency [4]. Now a days, this type of technology continues to gain popularity around the world. A multi-junction solar cell is consisted of two or more p-n junctions with dissimilar band gaps. A different part of the solar spectrum is absorbed by every junction in the solar cell. When photons hit the top of a single junction solar cell, they are absorbed if their energy is greater or equal to the band gap, otherwise, absorption will not happen. If the photon's energy is more than the band gap energy, the extra energy from the photon will be abandoned as heat. The concept of the multi-junction solar cell is based on the idea of using semiconductor materials with dissimilar band gaps to absorb different parts of the light spectrum. The thickness of the layers of the materials that make up the solar cell should be as skinny as possible so that the cost can be reduced. A well-designed multi-junction solar cell should have that ability to transform maximum light spectrum into current so that the external loads can be driven by it.

The solar cells consisted of silicon based materials are used all over the world which is up to 25% efficient [5]. The silicon source is ample in this world and good fabrication techniques have increased the availability of silicon based solar cells. However, silicon based solar cell efficiency is lower compared to the other types of solar cell such as III-V based solar cells[6]. The III–V zinc blende and wurtzite compound semiconductors materials are renowned for their tremendous performance as highly efficient solar cells. The III-V solar cells such as GaAs, InP, AlGaAs and GaInP are eminent for generating a higher efficiency more than 25% [7, 8].

$Al_xGa_{1-x}As$ is selected as the top cell absorber layer. It is a compound semiconductor which has a face-centered cubic crystal structure and a wide range of absorption coefficient ($\alpha \sim 10^5 cm^{-1}$) [9]. Indium phosphide (InP) is a binary semiconductor consisted of Indium and Phosphorus. It is a III-V semiconductor having a face-centered cubic crystal structure. $Al_xGa_{1-x}As$ and InP lattice constants are 5.6533+0.0078x Å and 5.868 Å respectively [10]. Based on the above criteria, it may be expected that a multi-junction solar cell made of $Al_xGa_{1-x}As$ and InP should be very efficient. In this paper, we propose a two-junction solar cell having $Al_xGa_{1-x}As$ as top cell and InP as bottom cell. Back to back connection is used to connect the two subcells.

II. MODELING AND SIMULATION

To understand the performance of $Al_xGa_{1-x}As$/InP multi-junction solar cell, the numerical simulation work is done by using Analysis of Microelectronic and Photonic Structures (AMPS-1D). It is a one dimensional device physics code that can be applied to any two terminal devices. The AMPS-1D software is capable of simulating the electrical features of diode, sensor, photo-diode, and photovoltaic device analysis. AMPS-1D can be used to generate I-V characteristics with or without illumination, photo diodes under voltage and light bias and so on. At present, AMPS-1D is used by more than 200 groups of researcher for solar cell design [11].

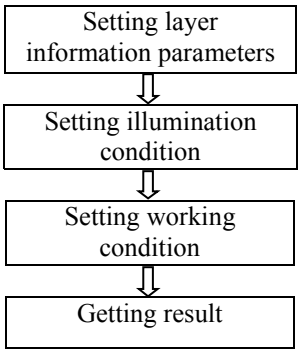

Fig. 1. General block diagram of simulation process of solar cell in AMPS-1D

The density of state (DOS) mode or the lifetime mode can be implemented for the simulation process by AMPS-1D [12]. Both modes are described in AMPS-1D manual [13]. Lifetime model is used in our simulation. The Poisson equation, the electron and hole continuity equations are three semiconductor device equations which are solved numerically by AMPS-1D [14]. The Poission equation, hole and electron continuity equations are given below respectively [15].

$$\frac{d}{dx}(-\in(x)\frac{d\psi}{dx}) = q[p(x)-n(x)+N_d^- - N_A^+ + p_t(x)-n_t(x)] \quad (1)$$

$$\frac{dp_n}{dt} = G_p - \frac{p_n - p_{n0}}{\tau_p} - p_n\mu_p\frac{d\xi}{dx} - \mu_p\xi\frac{dp_n}{dx} + D_p\frac{d^2p_n}{dx^2} \quad (2)$$

$$\frac{dn_p}{dt} = G_n - \frac{n_p - n_{p0}}{\tau_p} + n_p\mu_n\frac{d\xi}{dx} + \mu_n\xi\frac{dn_p}{dx} + D_n\frac{d^2n_p}{dx^2} \quad (3)$$

Here, Ψ represents electrostatic potential, n is denoted for free electron, p indicates free hole, n_t means trapped electron, p_t symbolizes trapped hole, N_D^- denotes ionized donor-like doping concentration, N_A^+ represents ionized acceptor-like doping concentration and ξ symbolizes electric field. These parameters are represented as a function of coordinate position x. G represents generation rate, D indicates diffusion coefficient, ε denotes permittivity and q symbolizes the charge of an electron. To calculate recombination current, Shockley–Read–Hall (SRH) model is used.

Fig. 1 explains the general block diagram of the simulation process of a solar cell in AMPS-1D. The basic structure of $Al_xGa_{1-x}As$/InP multi-junction solar cell is shown in Fig. 2. Standard Test Condition (STC) is considered in our simulation process. According to STC, cell temperature is 25 ^{0}C, irradiance is 1000 Wm^{-2} and air mass is 1.5.

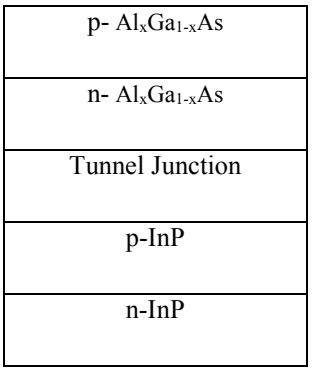

Fig. 2. Basic structure of $Al_xGa_{1-x}As$ /InP solar cell

More than fifty parameters can be varied in a specific solar cell model [16]. To work with fifty parameters is very abstruse and tiresome. So, the number of parameters should be reduced by keeping most of them as constant. It is very hard to select the accurate parameters that can be applied to simulate the various layer of a multi-junction solar cell model. For this simulation, the most important parameters are selected and summarized in Table I [17].

TABLE I. PARAMETERS USED IN SOLAR CELL SIMULATON

Layer properties	**p-AlGaAs**	**n-AlGaA**	**p-InP**	**n-InP**
Dielectric constant, ε	12.05	12.05	12.5	12.5
Electron mobility, μ_e [cm^2/Vs]	1100	1100	4000	4000
Hole mobility, μ_p [cm^2/Vs]	120	120	150	150
Carrier density, n or p [cm^{-2}]	p:1e17	n:1e17	p:5e16	n:5e16
Optical band gap, Eg [eV]	1.79	1.79	1.35	1.35
Effective density, N_c [cm^{-3}]	4.94e18	4.94e18	5.7e17	5.7e17
Effective density N_v [cm^{-3}]	1.74e19	1.74e19	1.1e19	1.1e19
Electron affinity [eV]	3.74	3.74	4.38	4.38

III. RESULTS AND DISCUSSION

Lattice constant has an effect on the band gap energy of semiconductor (cubic semiconductor). The band gap (E_g) is inversely proportional to the square of lattice constant [18]. The bandgap of $Al_xGa_{1-x}As$ absorber layer is varied from 1.42 eV to 1.79 eV according to the following Vegard's law [19].

$$E_{g,\,dir}(x) = 1.42\text{ eV} + x\,1.2475\text{ eV} \quad (4)$$

where $E_{g,dir}$ is the direct energy band gap of $Al_xGa_{1-x}As$ for $x < 0.45$ and x is Aluminum mole fraction in the $Al_xGa_{1-x}As$ alloy.

With the increase of x, the band gap is also increased. Effect of bandgap change on cell efficiency is depicted in Fig. 3. For x=0.3, E_g becomes 1.79 eV and the corresponding efficiency becomes 22.243%. It is the highest value of efficiency. So the band gap of the top cell is chosen as 1.79 eV.

A thin-film multi-junction solar cell is a second generation solar cell. It is created by depositing two or more thin layers. Currently, the thickness is varied from a few nanometers to micrometers which is much thinner than first generation solar cell. Thin-film solar cells are commercially used in recent times.

The thickness of a solar cell is a major parameter and choosing the optimum thickness is often an important factor [20]. One of the primary objectives of the present day's PV research work is making the cells thinner because diminishing the thickness reduces the creation time and fabrication cost. Lessening the semiconductor thickness of multi-junction solar cell decreases the semiconductor material expense as well as enhances the efficiency if the cell made with optimum thickness has a back-surface field [21]. When a solar cell absorbs light, an electron-hole pair is generated which must then be separated so that the charges can be put to use in a circuit. A large amount of energy will be reflected back if the cell is too thick [22]. Again, if the cell is too thin then it will not absorb most of the incident light as a thick one and the recombination rate will be increased. The increased recombination will result in decreased efficiency. Therefore, optimization in the thickness of the absorber layer is compulsory to gain the highest efficiency of solar cell.

The band gap of $Al_{0.3}Ga_{0.7}As$ is considered 1.79 eV as it will result in maximum efficiency. The p-layer thickness is varied from 20 nm to 150 nm and n-layer thickness is kept constant at 800 nm. The performance of the cell is simulated and outputs are represented in Fig. 4. From Fig. 4, it is observed that the thickness greater or less than 100 nm causes the efficiency to be reduced. So the p-layer thickness is fixed to be 100 nm.

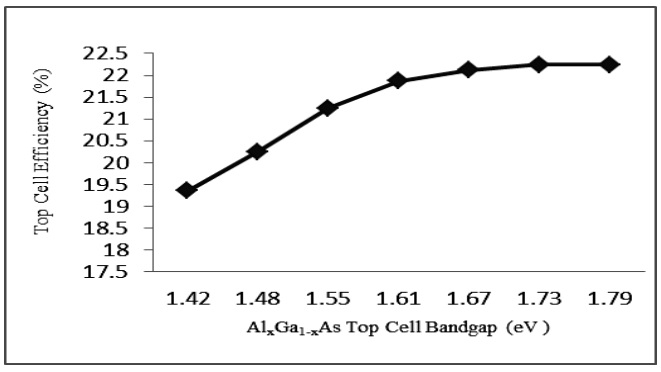

Fig. 3. Effect of top cell band gap change on efficiency

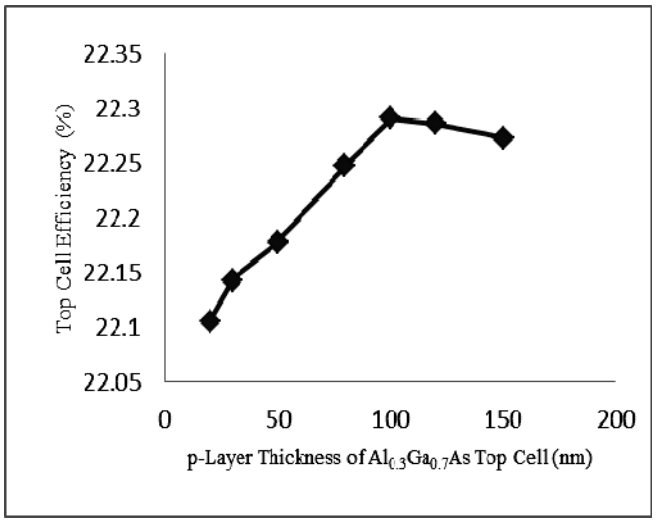

Fig. 4. Effect of p-layer thickness on efficiency for top cell

The band gap of InP is 1.35 eV. The thickness of n-layer is varied from 100 nm to 7000 nm and p-layer thickness is fixed at 200 nm. The performance of the cell is simulated and the results are shown in Fig. 5. If the absorber layer is thinner than 5000 nm it will cause a reduction in efficiency. On the other hand, the absorber layer thicker than 5000 nm causes no significant change in efficiency. So, the n-layer thickness is chosen as 5000 nm.

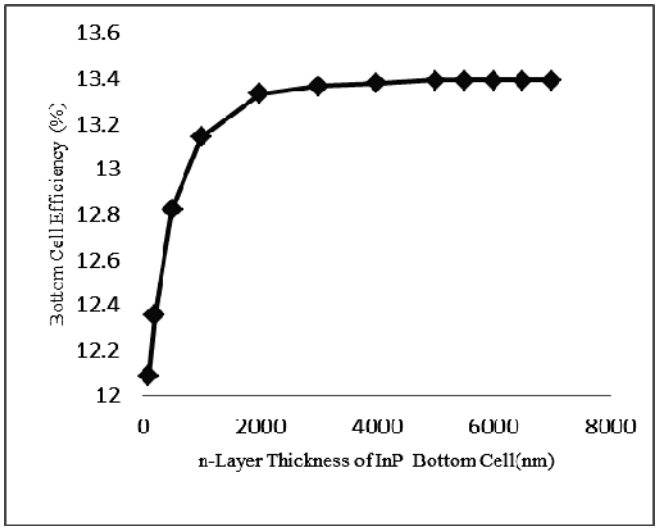

Fig. 5. Effect of n-layer thickness on efficiency for bottom cell

TABLE II. SIMULATED SUB CELLS RESULTS

Cells	Open Circuit Voltage (V)	Short Circuit Current (mA)	Fill Factor	Efficiency (%)
Top	1.539	15.783	0.916	22.247
Bottom	0.846	18.552	0.858	13.460

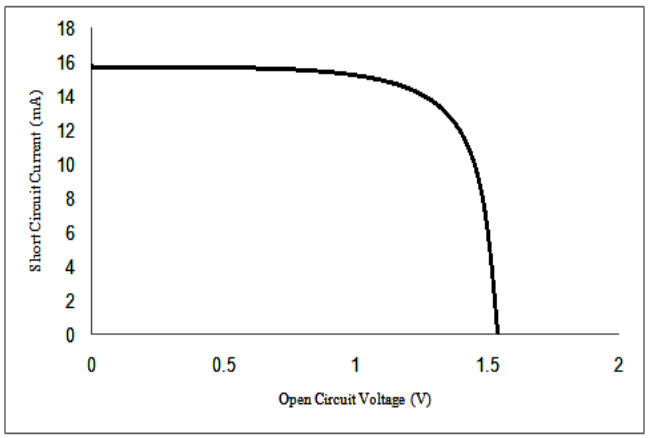

Fig. 6. I-V curve of $Al_{0.3}Ga_{0.7}As$ top cell

A perfect choice of the materials can give extended spectral coverage and thickness, bandgap optimization leads to an increase in overall power conversion efficiency [23]. In the baseline case from [17], the subcell efficiency of $Al_{0.3}Ga_{0.7}As$ and InP was 21.034% and 13.329% respectively and the overall efficiency of $Al_{0.3}Ga_{0.7}As$/ InP multijunction solar cell was 34.363%. Simulated subcell results are shown in Table II. The $Al_{0.3}Ga_{0.7}As$ top cell efficiency is 22.247% and the InP bottom cell efficiency is 13.460%. The I-V curve of $Al_{0.3}Ga_{0.7}As$ subcell is shown in Fig. 6. The I-V curve of InP subcell is depicted in Fig. 7. The I-V characteristic curve of $Al_{0.3}Ga_{0.7}As$/ InP multi-junction solar cell is represented in Fig. 8.

Open circuit voltage and fill factor decrease with the increase of operating temperature because bandgap slightly decreases and short circuit current increases with a decrease in the bandgap. As a result, with an increase in operating temperature efficiency decreases. If the normalized efficiency of a solar cell decreases linearly when the operating temperature is increased then the solar cell has better thermal stability [24]. The temperature is varied from 0 ^{0}C to 70 ^{0}C and the result is shown in Fig. 9. We observe that the normalized open circuit voltage decreases almost linearly that indicates the thermal stability of this proposed multi-junction solar cell.

IV. Conclusion

In this research work, we have designed and optimized a relatively thin $Al_{0.3}Ga_{0.7}As$/InP multi-junction solar cell. The simulated performance parameters of $Al_{0.3}Ga_{0.7}As$/InP multi- junction solar cell are V_{oc}=2.385 Volts, J_{sc}=15.789 mA/cm^2 and FF=0.88. The power conversion efficiency of the multi-junction solar cell at 298 K is 35.643%. The thermal stability of the proposed solar cell is also better. The proposed multi-junction solar cell is depicted in Fig. 10.

***Abstract*— Demand of energy is increasing in the whole part of the world, it is estimated that in near future a significant energy crisis will be occurred. Furthermore, fossil fuels play a noticeable role for environmental pollutions. So, an alternative clean and environmental amiable renewable energy source is the most significant demand for the modern scientists. Bio-fuel cell especially microbial fuel cell can partially eliminate this crisis by producing electricity from biodegradable waste. Considering this aspect we produced double chamber MFCs where Zinc and copper plates are used as anode and cathode materials. In this study urine and fish waste mixed waste water are used as a source of substrate, aerobic bacteria helps to decompose it, in anode chamber where oxygen amplifies the reduction reaction in cathode chamber. To find out the effects of urine and fish waste on the performance of voltage, current and power we used digital multimeter and Hantek 365A data logger. Urine mixed waste water gives the maximum voltage 1.02 V, current 1.67 mA and power 1.7034 mW, whereas, for fish mixed waste water these values were 0.968 V, 1.365 mA and 1.3213 mW respectively. The whole operation we done batch wise, initial pH 8 and cell volume was 5 liter.**

Keywords— MFC, Urine, Fish, Electrode, Renewable.

I. INTRODUCTION

Energy is used to do everything from walking to sending astronauts into space. Energy is essential to all living organisms. The sun is the source of all the energy available on Earth. Energy choices and decisions impact Earth's natural systems in ways we may not be aware of it, so it is essential that we choose our energy sources cautiously. The authentic value of energy is more than just dollars and cents; there are significant economic, political and social factors and consequences to consider as well [1]. The importance of energy sources is increasing day by day and we need to conserve energy that will continue over the next few decades. Nonrenewable energy sources thrust into fossil fuels that come from beneath the ground and take thousands of years to form. Renewable energy sources are developing quickly and can supply a region with its long-term energy needs far into the future. Fossil fuels contain energy held millions of years ago from sunlight by living organisms. The energy in fossil fuels such as oil, natural gas, and coal comes from energy that producers captured from sunlight long ago. Energy stored in these fuels is liberated by burning them, which also releases carbon dioxide into the ambience [2].

Renewable and nonrenewable energy sources are mainly used as an elementary source of energy further it used to produce electricity. Nuclear energy is produced from uranium, a nonrenewable energy source whose atoms are split through a process called nuclear fission to create heat and, eventually, electricity. Microbial fuel cell (MFC) is a bio-electrochemical system [3] that drives an electric current by using bacteria and mimicking bacterial interactions found in nature. The first MFCs, exhibited in the early 20th century, used a mediator: a chemical that transfers electrons from the bacteria in the cell to the anode. Around the year 1970s unmediated MFCs emerged in the history of MFC, where bacteria electrochemically active redox proteins can transfer electrons directly to the anode [4]. In the 21st century MFCs inaugurated to find a mercantile use in wastewater treatment [5].

Microbial fuel cells have manufactured a pregnant posterior for human beings and the planet we live on. The research done so far and with the infliction that we have currently will help the reduction of our need to use fossil fuels and allow us to reach energy from wastes products, bacteria ridden water, enable us to use prior salted water to drink, farm with, this will greatly benefit 3rd world countries and areas plagued with drought where there is no electricity. Microbial Fuel Cell (MFC) may be such a renewable energy source for the coming decades. Microbial Fuel Cell (MFC) may be such a renewable energy source for the next decades.

In this research we compared the effect of additives (urine and fish waste) on the yield (current, voltage and power) of microbial fuel cell. For both cases the experiment was done in batch wise and length of time was nine days.

II. MATERIALS AND METHOD

A. Cell Construction

Two chambered MFC was constructed with batch operation. Both anodic and cathodic chambers were made up of glass (volume) with two openings, one for addition or removal of sample and other joining for the other chamber. Each chamber had 5000 ml working volume. The two chambers were connected using an agar salt bridge with a length and diameter of 5 cm and 0.5 cm respectively. The joints were covered by M-seal to prevent the leakage. Two similar sized zinc (Zn) and copper (Cu) electrodes were used as anode and cathode. Anode and cathode were joined to the copper wires, which in turn were commenced. The anodic chamber contained municipal wastewater which had following composition (per liter): 0.02g NH_4Cl, 0.015g $CaCl_2.2H_2O$, 0.33g KCl, 0.33g NaCl, 0.015g $MgSO_4.7H_2O$, 0.001g $CuSO_4.5H_2O$, 0.001g $ZnSO_4.7H_2O$, 0.001g $MnSO_4$, 0.1N Phosphate Buffer (pH 7), 5% Dextrose. The cathodic chamber contained 0.1M potassium sulphate prepared in 5000mL volume. Here also used microbe which was collected from micro-organism sources. This operation is shown in is fig. 1.

Fig.-1. Schematic diagram of two-chamber microbial fuel cells

B. Substrate Collection

We used municipal waste water and fish waste as substrate. The municipal waste water was collected from the municipal waste storage and the fish waste was collected from fish market.

Fig-2. Source of substrates

C. Salt bridge preparation

For the preparation of salt bridge we had to pass two steps. Firstly we had made 0.1M salt solution with 5gm agar. Finely ground salt such as table salt dissolves much faster than coarsely ground salt (rock salt). If the solution is warms the agar will begin to melt, warm the agar until it becomes liquid. We heated much to mix well to dissolve the salt in the agar. After mixing well we removed it from the heat. Then some pieces of gauge cloths were kept into the solution and then kept it for 2-3 hours. Then that we had prepared the agar/salt electrolyte solution we filled the salt bridge with it. A short PVC pipe about 4-5cm long was filled with the gauge which absorbed the agar-salt solutions.

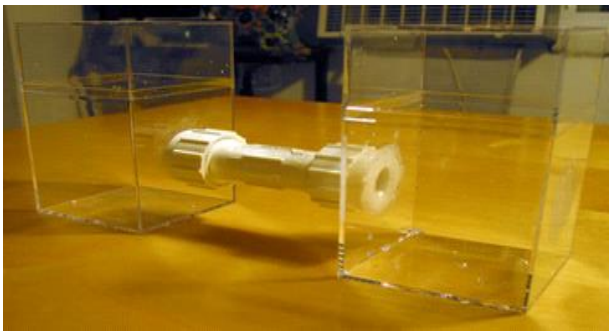

Fig-3. Salt bridge preparation

D. Microbe

We obtained our algae culture from natural sources. We went to a local lake; a swamp is good to have one. We were looking for bottom feeders which indicate a rich organic base. We mixed the mud with a portion of cow waste and also mixed a little portion of sugar and then mixed them very well. After that we kept the mixer in an anaerobic condition.

E. Constructing the Electrodes

As electrode (anode and cathode) we used Copper (Cu), zinc (Zn) and carbon felt. We used Zn as anode and Cu as cathode in both electrochemical cells. Then we used Cu wire for connecting the both electrode. Wire layers should be placed on the outside to contain the carbon paper and maintain integrity of the electrodes in the mud or sand.

F. Data Collection ad Data Analysis

Data was collected through manual and automatic in both systems. We used a digital multi-meter and measured voltage and current at fixed interval. For automatic data collection, we used Bluetooth/USB Data Logger named Hantek 365A which was connected to a computer with the B-Type Plug of USB cable to Hantek365's USB port provided by the manufacturer. Based on the recorded voltage, the current and powers were calculated using the following equations:

Current

Current was calculated using Ohms law:

$V=IR$

Current density:

$I_{anode} = I/A = V/(A*R)$

Where, V=Voltage; I=Current; R=External resistance; I_{anode}=Current density; A=Area of the anode electrode

III. RESULT AND DISCUSSION

A. Result

For this experiment we constructed rectangular shape double chamber microbial fuel cell. The operating condition for whole process was pH-8, electrode distance 5cm and operating temperature ranges from 25 to 30 degree centigrade. Here we mixed 10% (w/v) both urine and fish waste with municipal waste water and electrode pair was Zinc and Cupper.

Fig-4 compares the current obtained from urine and fish waste mixed waste water. From here it is clear that the obtained value from urine mixed waste water is higher than fish waste mixed waste water. Maximum current obtained from urine mixed waste water was 1.67 mA whereas, for Fish waste result was 1.365 mA, both results was obtained in the first day of operation. Then the current decrease sharply, after 3 days this rate became slow. After nine day operation the value was0.386 mA and 0.247 mA respectively for urine and fish waste mixed waste water.

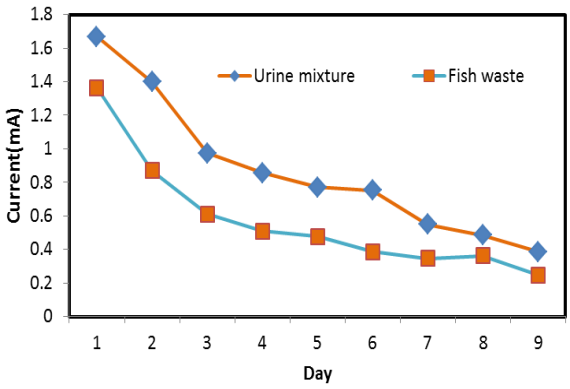

Fig-4 Change of current with time

Our findings is higher than Kamau et al [6], where he used cow dung and got a maximum current 1.156 mA. In fig-5 total current in nine days operation was 7.84 mA and 5.178 mA for waste water and fish waste respectively.

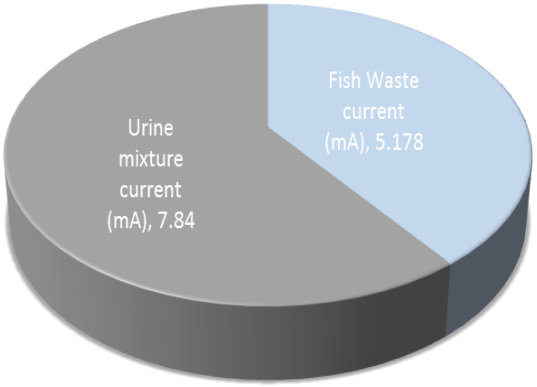

Fig-5 Total current of waste water and fish waste

Figure-6 shows the variation of the voltage for two additives urine and fish waste with municipal waste water. In first day of operation maximum voltage for urine mixture was 1.02 V, which was 5.1% higher than fish waste mixed waste water (0.968 V). Voltage decreased from 1.02 V to 0. 545 V and 0.968 V to 0.602 V for waste water with urine and fish waste respectively from first day to five day then declined slowly for both two. Finally after nine days operation the voltage (0.49 V, and 0.388 V) were reached for both sample, this was done because for the formation of biofilm on the anode surface. Our finding is much higher than Simeon and Raji 2016 [7], where they got 731 mV by using urine in soil based MFC. Fig-7 shows that in 9 days operation total voltage produced 6.871 V and 5.851 V for urine mixed and fish waste mixed waste water respectively.

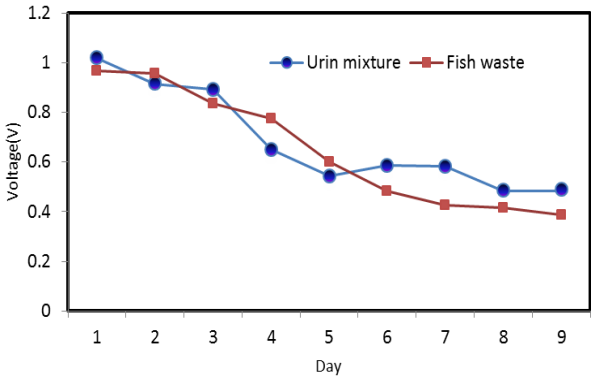

Fig-6 Change of voltage with time

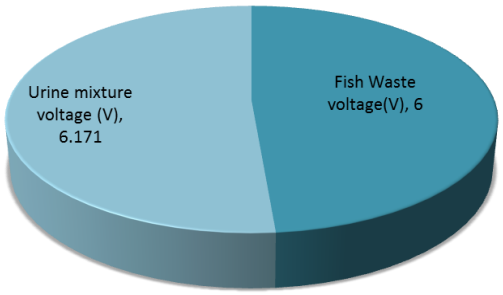

Fig-7 Total voltage of waste water and fish waste

The figure-8 below compares the power obtained for waste water mixed with (10% w/v) urine and (10% w/v) fish waste. At first day the obtained value was 1.7034 mW for urine mixture and 1.32132 mW for fish waste mixture. Then the power decreased for both connections, after three days operation the yield for both cases decreased slowly. These findings are higher than Kamau et al [6], where he got 0.0045 mW using cow dung. In fig-9 the total power were 6.017362 mW for urine mixed waste water and 3.929824 mW for fish waste mixed waste water.

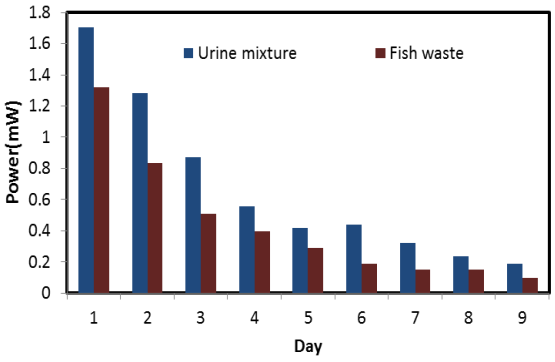

Fig-8 Change of power for waste water & fish waste

Fig-9 Total power for nine days

B. *Discussion*

In our experiment we find that cow urine is better than fish waste for generating power from microbial fuel cell. This experiment can be used for society when we store the current in a capacitor. Our result is higher than Ogugbue et.al 2015 [8], where they got maximum power 0.355 mW by using copper and carbon electrodes but we used zinc and copper electrodes with same electrode distance, again it was higher than both Kamau et al [6] and Simeon and Raji 2016[7].

IV. CONCLUSION

Urine as well as fish waste are prominent activator for waste water treatment in microbial fuel cell. The process we observed for 9 days, urine mixed waste water gives 5.12% higher voltage, current 34.1% and power 34.68% than fish mixed waste water. All these cases urine mixed waste water gives higher yield than fish mixed waste water, because some vitamins (citric, succinic acid, carbolic acid), minerals (lactose, calcium salts) ions such as Na, N, Mg, Fe, Si, Cl, Mg, P, K, S and enzymes are present in cow's urine [9], again fish waste contain average 2.83% nitrogen (N), 2.54% phosphorus (P), 0.10% potassium (K), 6.99% calcium (Ca), and 0.53% magnesium (Mg) on a dry-weight basis [10]. So that urine is a better electrolyte than fish waste.

ACKNOWLEDGMENT *(Heading 5)*

We would be very much grateful to the authority department of Chemical Engineering, Jashore University of Science and Technology (JUST). We are also grateful to the officers and staff of the central laboratory of JUST, who helped us in whole experiment.

Abstract— **The world's total population and the total number of vehicles are increasing day by day. The consumption rate of total power is also rising. Sometimes it becomes a big problem to provide the nation with enough power in underdeveloped or a developing country only because of the high-power consumption by the consumers. It is also observed that the road line continuously consumes a huge amount of electricity, and this amount of electricity can be saved if a controlled process can be operated on the road. In order to save the waste of electricity from the road and to operate street light in a controlled manner, an intelligent lighting system is introduced with a Piezo electricity generator. With the appearance of vehicles or people on the road, the light intensity can be changed in this system. This system also introduces the zebra crossing light to warn a driver at night when a person passes a road using the zebra crossing. This warning from the zebra crossing light can save a person from an accident. Another special feature of this system is the Piezoelectric generator, which provides extra electricity. In this system, several components are used to operate the system properly. Light Dependent Resistor and Ultrasonic sensor are used to control street lights by sensing night and day or by detecting vehicles or pedestrians at night. The lights at the zebra crossing point are controlled by a Passive Infrared Resistor. All these features of this system will provide an uninterrupted supply of electricity as this system can make a major contribution in saving a country's most needed energy.**

Keywords— Ultrasonic sensor, Light Dependent Resistor, Piezoelectric generator, PIR sensor.

I. INTRODUCTION

With the rise of civilization, every day counts for new progress in different aspects of life. At the beginning of civilization, there were fewer streets for lesser population than now. However, with the population growth, the demands and facilities used by consumers have accelerated. As a result, to fulfill the demand of this increased population, better transportation facilities need to be provided along with the assurance of safer road. The economic growth of a country is highly dependent on power supply, communication and transportation system.

However, as Bangladesh is a developing country, the street facilities are not properly managed and executed. Among many other reasons, poor lighting system is one of the major concerns of the government. It has been also observed that unwanted situation like robbery, snatching, hijacking, sexual harassments etc. are also occurring daily where the street-light facilities are not up to the mark [1].

In Dhaka city (Capital of Bangladesh) about 420MW power is wasted every month for not turning on/OFF the street light on the right time. It is observed that street lights are turned ON usually one or two hours before sunset and are turned OFF
one or two hours after sunrise. This is happening because of a very poor monitoring system and some other issues. As a result, 34 lakh (BDT) is wasted every month. These wasted powers could be used to fulfill the demand of 4,000 non-urban households [2].
In the conventional system, street light is controlled from the control station and they keep turned ON the street light every day from 6 PM to 7 AM [3].

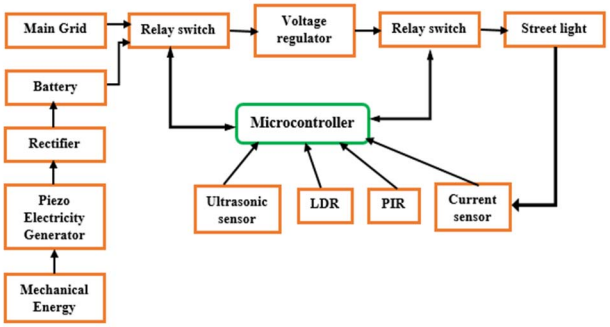
In Bangladesh, people face snatching, robbery, hijacking, sexual harassment every day. These types of incidents

happen at a place where the street light is insufficient. To overcome the insufficiency of light we have designed a system which will provide maximum light when a single person is available on the street or at a bus station. This system will work automatically to turn on or OFF the light.

Bangladesh is a developing country and its development depends on power supply but there is huge lacking of power supply in this country according to the total demand. Total production of power is not sufficient in Bangladesh but a huge amount of power is wasting every day for street light. This wastage can be reduced, if the street light can be controlled through an efficient system. Our smart street light system with Piezoelectricity generator will control those lights by turning it on or OFF at an exact time. This system can operate the lights in several modes. The street lights can be kept turned ON or OFF and also its intensity can be controlled according to the appearance of the people or the vehicles with self-light or no light.

This system will also work for the pedestrians using zebra crossing. When a person will walk through the zebra crossing line, the lights beside the line will turn on automatically and will warn the driver at night. This system works in such a manner by which a huge amount of electricity can be saved from the street light consumption and the Piezoelectricity generator produces electricity by itself with the help of the running vehicles and stores it in a battery. Through this system another source of electricity is added for the street light and if there is a load shedding or other issue of absence of electricity from the national grid, then the street light can operate itself by the stored energy. This system will also provide a ceaseless supply of electricity and the roads will be safer than the existing ones.

This system will detect the day-night situation and will turn on/OFF the light automatically. This system will detect the darkness even in daytime. This system will work even in the rainy days when sufficient sunlight is unavailable. Another problem is found that street lights are not operational. It is a common scenario where several numbers of street lights are found damaged or malfunctioned in a particular place. Our system will detect the damaged light immediately and this information can be monitored from a control station so that the damaged light can be replaced as soon as possible. Combining all these features our system will not only work for reducing the power consumption of street light but also ensure a safer life and efficient monitoring system of the street-light.



II. INTEGRATED EQUIPMENT

Various types of components are embedded in this system to make the project effective. The particular combination of all these equipment makes this system comparatively accurate and user-friendly. The main characteristics of these components are described below.

No. of component	No. of unit	Features of these components for this project
Arduino Mega	1	• Main processing unit. • Both analog and digital pins are used. • 5V is used to operate all of the components. • To power up the Arduino 9V is used in this project.
Piezo electric generator	5	• To convert mechanical energy to electrical energy.
Light-dependent resistor	6	• 1 LDR sensor is used to detect day or night period. • Rest of the LDR sensor detects the light of the vehicle.
Ultrasonic sensor	5	• To detect objects. • Person or vehicle both can be detected.
Current sensor	5	• To check malfunction in every individual pole.
Relay switch	1	• For switching purpose.
Voltage regulator	1	• To operate the device in fixed voltage.
Rectifier	1	• Convert AC signal to DC signal.
Led light	15	• Used as a street light.
PIR sensor	2	• To detect human.

III. SYSTEM DESCRIPTION

A. Block diagram

The above figure shows the block diagram of the system. In this diagram, all the components used in this system are shown and this diagram mainly describes the overall system in a single figure. In this system, several components are used as inputs and outputs. Main grid and a battery are the two-power sources of this system. The battery reserves its power from the Piezoelectricity generator. The microcontroller is the main control unit of this system.

Several components are connected with the microcontroller. Relay switches, ultrasonic sensor, Light Dependent Resistor, Current sensor, street lights, all are connected with the microcontroller. The details of the system are given below:

The system is operated by two power sources. The main power source of the system is the main grid line and another power source is the battery. The battery reserves its power from the Piezoelectricity generator. Piezoelectricity generator will produce electricity by converting the mechanical energy into electrical energy. Then the converted electricity is rectified with the rectifier. To store the power into battery, AC needs to be converted into DC. Both of the power sources are connected to a relay switch and that switch is connected to a microcontroller. The relay switch and the microcontroller are connected to each other to create a feedback system. At first, the microcontroller checks the power of the battery. If the power is sufficient to operate the system, then it allows the battery to give the power otherwise it allows the main grid to operate the system. Then the supplied voltage either from the grid or from the battery is passed through a voltage regulator to maintain a stable voltage in the system. LDR and Ultrasonic sensor are connected with the microcontroller and all of them work together to detect the vehicles or human in the street. The ultrasonic sensor actually detects any kind of object in the street and then LDR checks whether the object has its own light or not. Depending on the signal from the LDR, microcontroller takes the decision to operate the street lights through relay switches. PIR sensor is used in the zebra crossing line and in the bus station to detect the human. When a person walks on the zebra crossing line to cross the road, the corresponding lights for the zebra crossing line will turn ON. It will give a warning to the driver and the zebra crossing line will be focused brightly.
The same procedure is used for the bus station. When a person appears at the bus station, the PIR sensor detects the presence of the person and the microcontroller allows the bus station's lights to be turned ON. The current sensor is used in this system with the microcontroller to detect the malfunction of the system. If any kind of malfunction is detected in the system, the microcontroller will send a report to the control room to take a step immediately. This is the system description of the system.

B. simulation

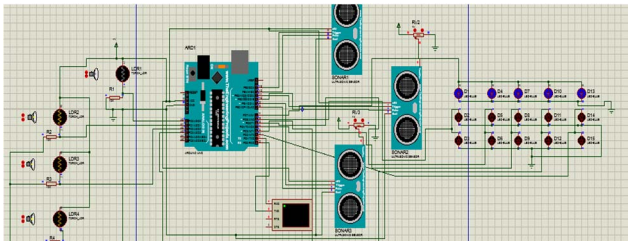


Fig 2: General night condition (minimum intensity) without any object.

In this figure, it is seen that the main LDR (LDR-1) senses lower light from the surroundings. The system is detecting the environment as a general night condition. In this situation, the LED's D1, D4, D7, D10, D13 are turned ON and the rest of them are turned OFF. This situation is treated as a normal night condition without any objects so the four LED's are turned ON and this is the minimum light intensity of the system.

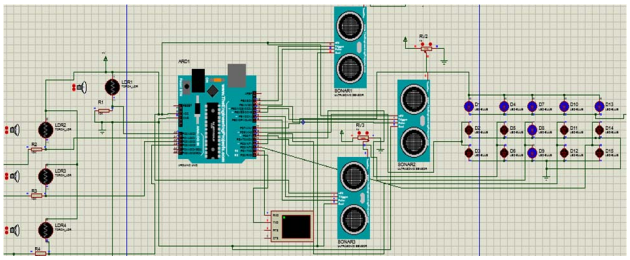

Fig.3: Maximum intensity of a particular pole with detection of human.

In this figure, a condition with the detection of a person in the system is shown. A person is under the pole no.3 and this triggers SONAR3 turning all the lights (D7, D8, D9) of pole 3 ON, whereas in other poles, only one light is turned ON for each. This picture actually shows the condition when a person will cross a certain pole on the road and the corresponding pole will give the maximum intensity.

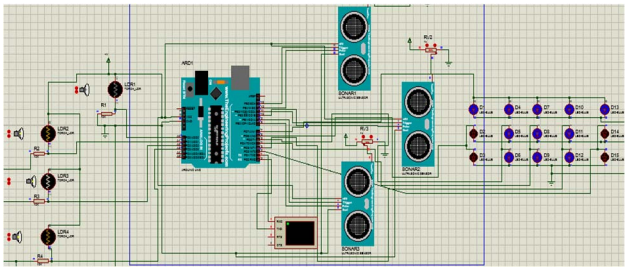

Fig 4: Maximum intensity of three poles at a time with detection of vehicle.

Fig.3 shows a condition that describes a situation with a vehicle running on the road. When a vehicle will pass the road, all lights of the three poles will be turned ON. In this figure, it is shown that when a vehicle with self-light is approaching towards the poles, LDR2 and SONAR2 get triggered and all lights of pole2, pole3, pole4 are turned ON. This figure actually describes such a condition that when a vehicle will be passing the road, corresponding three poles will give the maximum intensity.

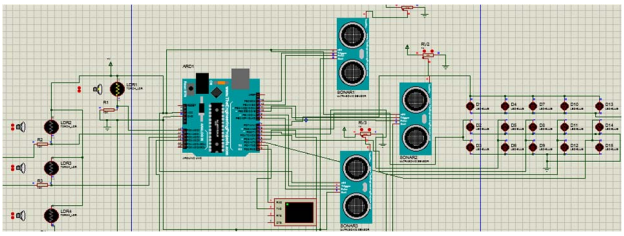

Fig 5: Normal daylight condition.

Figure 5 shows the normal daylight condition when the LDR1 senses the daylight from the surroundings. It gives a signal to the microcontroller and all lights of the poles will remain completely turned OFF. In this situation, even if there is any person or vehicle on the road, all the lights will be turned OFF in any situation.

IV. Overview of the Prototype

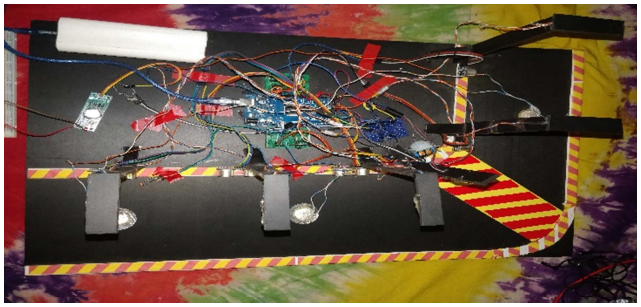

Fig6: Prototype of The System.

A prototype was made for describing the system properly. In this prototype in each street light pole, there is a combination of ultrasonic sensor and LDR. Another LDR is situated at a different place which is far from the street light pole. This LDR works as the main LDR of the system. It detects the day/night condition by measuring the natural light intensity and gives different signals to the microcontroller. A PIR sensor is used in the zebra crossing line and at the bus station to detect the human appearance. In this portion the details of the prototype are given below:

Fig7: Low light detection of the surrounding

Fig.7 shows an overview of the prototype during night. In this figure, it is seen that the street lights are turned on with a minimum intensity. When surrounding lights are lower, at that time the street lights are turned on with its inbuilt automation system.

Fig 8: Detection of objects with self-light

Fig.8 shows the condition of the system when an object having self-light approaches towards it. when a vehicle or any object will run on the road with its self-light turned on, the street light will be operated in such a way that the vehicle gets the proper light on the road. When the vehicle keeps running on the road, three lights will be turned on at a time with high intensity and after passing each street lamp, it will be turned OFF automatically. This system actually shows that there will be a number of three lights which will give the light for the passing vehicle.

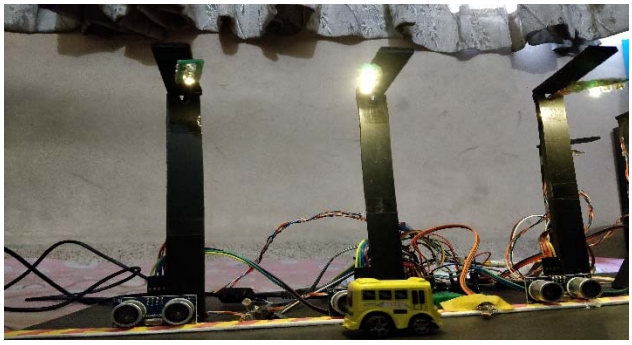

Fig9: Detection of objects without self-light.

Fig.9 shows the condition of the system when an object without self-light approaches towards it. When a person will walk on the footpath, a street light will be turned on immediately. When the person will reach under the next street light, that light will be turned on and the previous one will be turned OFF automatically.

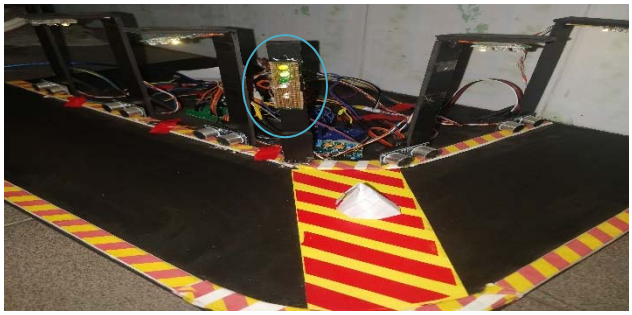

Fig10: zebra crossing point.

Fig.10 shows the zebra crossing point of the system. When a person will walk on the zebra crossing line to cross the road, the PIR sensor will detect the human and give a signal to the microcontroller to turn on the corresponding lights. Those lights will focus the zebra crossing line brightly and will give a warning to the drivers. The bus station's lights were operated in this prototype in the same manner as the zebra crossing lights.

V. Prototype Cost

SL NO.	Component List	Price Per Unit (US Dollar)	Quantity	Total Cost (US Dollar)
01.	Arduino Mega	$10	1	$10
02.	Battery	$5.95	1	$5.95
03.	Piezo electricity generator	$0.35	15	$5.25
04.	Rectifier	$0.85	1	$0.85
05.	Voltage regulator	$2.35	1	$2.35
06.	Relay module	$9.5	6	$57
07.	Led	$0.02	15	$0.3
08.	PIR sensor	$0.95	2	$1.9
09.	Ultrasonic sensor	$0.95	5	$4.75
10.	LDR sensor	$0.12	6	$0.72

11.	Current sensor	$2.35	5	$11.75
12.	Total Cost			$100.82

VI. Features And Comparative Advantages

Features available in the device:

- Smart lighting system to ensure safe road.
- Reduces the waste of electricity.
- Minimize the power consumption using led light.
- Reduce the dependency on the main grid connection.
- Easy to implement as it is cost-efficient, eco-friendly, robust and relatively accurate.
- Smart lighting system on the zebra crossing point.

Comparative advantages of the device:

There are lots of smart street light systems proposed earlier. One of those paper [4] is about IOT based smart street light energy saving system. In that system LDR sensor used to ON/OFF the street light according to the availability of surrounding light intensity level. Ultrasonic sensor used to detect vehicle or person when comes to the range then automatically increase the intensity level up to 100% of road light. In that system, there is no zebra crossing light system, absence of detecting a bus station having people or not, absence of Piezoelectricity generator and especially the damaged light monitoring system, while in our designed system all of these features are added parallelly.

In another [5] paper it was proposed that street light is controlled based on TRIAC. TRIAC controls the voltage level for varying the intensity of street light according to the traffic which is measured by sensor and based on sunset or sunlight which information comes from Internet source as power electronic circuits are combined with IOT. In this paper TRIAC based control system was proposed and IOT was also proposed. In that paper, there was also absence of Piezoelectricity generator, monitoring and detecting of people at a bus station, automatic light of zebra crossing line as well as the monitoring system of the damaged light.

Another [6] paper described street light monitoring and control based on WSN. Integrated doppler sensor was used for detecting vehicle and helping to increase the efficiency of power consumption. Current sensor was used to identify any possible malfunction. This paper came with the feature of detecting malfunction but they could introduce Piezoelectricity generator to produce more power and to save the power consumption from main grid. They could introduce the zebra crossing line system and monitoring system of a bus station. Our system will work with all these features as well as malfunction detection.

In [7] this paper, design was proposed about intelligent control of road light and reducing the power consumption by LDR, IR sensor and all of the components are connected to microcontroller. ARDUINO Uno used as microcontroller. This system also missed some features that could be included in it. They also did not introduce with another power source which could be used when the electricity supply is OFF. There is no malfunction monitoring system, zebra crossing light system as well as people and vehicles detection system. All this combination could be used on that system to make the system much better.

In [8] this paper Piezoelectric sensor was used to observe vehicle movement and save power by controlling the intensity of road light. Piezoelectric sensor was used to make the project cost-effective. ZIGBEE technology used to connect between circuit and IOT for storing information about vehicle and people. This paper appeared with an extra feature of ZIGBEE technology but there was no malfunction detection system. People or vehicles detection system was also missing in this paper. These features could be integrated to the paper to make the system more efficient and robust.

The author of [9] this paper used Piezoelectric material as the source of energy of street light. It is cost efficient and renewable energy source so the whole project easy to implement in a large scale. Full wave rectifier circuit was used to develop power extraction capability from Piezoelectric harvests. This paper proposed that there was no another electricity supply except Piezoelectricity generator but this system sometimes may face some trouble to supply enough amount of power. In Dhaka city about 420 MW is consumed by the street light consumes in every month [2]. This huge amount of power may not be produced by the only Piezoelectric material and in a rainy day or in a holiday this production may be reduced very badly. This paper also did not propose any system of automatic light controlling, zebra crossing line and especially malfunction detection. These features could be added on that system.

VII. Novelty Of The Project

This project is feasible for two reason. Firstly, a new smart lighting system is established at the zebra crossing which will allow the drivers on the road notice a person crossing the road letting a secured crossing of the pedestrian. This can greatly reduce the accidents that happens on the road due to lack of visibility or awareness by the drivers.

Secondly, this system will be established even on the bus stand light which will only turn ON when any passenger or person is near the stand leading to lower and efficient power consumption.

The above given points prove the feasibility of the project and similar type of advantage can be established to every other lighting system based on the requirement.

VIII. Limitations

Our design system is prototype design as here a few amounts of piezoelectric material are used as a result it is difficult to charge a battery with less time. It will be beneficial If it is used on a large scale and the number of piezoelectrics is increased then it can possible to charge a battery with less time.

IX. Future Aspects

This project can be improved by adding image processing technology to detect a car or person more accurately. By

using this technology if someone breaks the traffic signal in the night period then the details information of that vehicle can be identified easily.

X. Conclusion

From this project, we have not depended only on the grid connection as sometimes it is not available due to lacking electricity so piezoelectric material plays an important role by providing a renewable source of energy. These unique features of this system will provide an uninterrupted supply of electricity as this system can make a significant contribution to saving the most needed energy in a country. Power consumption is reduced as light intensity in this system can be changed with the appearance of vehicles or people on the road. Led light is used here which is eco-friendly and cost-efficient. The zebra crossing light warns the driver at night when a person crosses the road through the zebra crossing.

Electrical and Morphological Characterization of Zinc-Doped α- Fe_2O_3 Thin Films at Different Annealing Temperature

Arman Ibn Shahjahann[1], Abu Bakar Md. Ismail,
Department of Applied Physics and Electronic Engineering, University of Rajshahi,
Rajshahi 6205, Bangladesh
swaran.apeeru@gmail.com

Abstract— **α Fe_2O_3 is naturally n-type material. Zn was used to dope α-Fe_2O_3 (Zn: Fe_2O_3) to turn it into p-type. The thin film of Zn: Fe_2O_3 was obtained by spin coating a blend of Zinc acetate (Zn $(CH_3COO)_2$ $2H_2O$) and $FeCl_2$ after annealing the film in air. Zn-doped-Fe_2O_3 was found as a p-type semiconductor by Hall Measurement. Effect of annealing at 450°C and 550°C temperature on electrical properties were also investigated. The resistivity of those films was found to be between 1~10 Ω-m. It was observed that the resistivity of the films increases with increasing temperature for most of the sample. It was also observed that the resistivity of the film is inversely proportional to the increasing number of film layer and thickness within most of the sample. Atomic Force Microscopy (AFM) was used to observe the surface morphology of the annealed film on glass substrate. The variation of the average roughness of annealed film on the glass substrate was from 60nm to 98nm and the thickness was 160nm to 540nm.**

Index Terms—*Thin film, Zn-doped-Fe_2O_3, Resistivity*

I. INTRODUCTION

Non-conventional energy sources have a great significance for the world's future, given the environmental issues related to energy generation and energy's importance in our society. To overcome a predictable energy crisis, there are intense researches on alternative energy harvesting techniques [1-3] . Solar energy is a good solution for these energy crises [4]. Hematite (α-Fe_2O_3) is an attractive material for PEC(photoelectrochemical) studies due to its ban-gap (Eg = 2.2 eV), lying nearly in the optimum range for the solar splitting of water.Based on this band gap, solar energy has absorbed were sun emits maximum energy. Besides, α-Fe_2O_3 is naturally abundant in the earth's crust and is, therefore a low-cost material. It is also corrosion-resistant in acidic and alkaline medium [5-10]. One major drawback of Fe_2O_3 is its unfavourable photo-response that arises mainly due to its low conductivity and consequent recombination of photo-generated carriers. Moreover to make a homo-junction of Fe_2O_3, which is naturally, n-type, p-type conduction in Fe_2O_3 is needed that is long-term stability.

After the first report of Fujishima on photo-assisted electrochemical water oxidation on TiO_2 in 1972[11] researchers have been investigating the wide bandgap metal-oxide semiconductors such as titanium dioxide (TiO_2), zinc oxide (ZnO), iron oxide like hematite (α-Fe_2O_3) and tin dioxide (SnO_2) for their application in solar cells, solar fuel, photocatalysis and energy storage devices [12-18]. In our recent past, Photoresponse of p-Type Zn:Fe_2O_3 Oxide Thin Films has been investigated by William B. Jr, John P and U. M. Khan. [19]

One of the fundamental aim of this research to make p-type Zn doped Iron(III) Oxide thin films, analyzing their electrical properties and to learn the fabrication which can be used as a solar cell or homojunction material for any kinds of semiconductor device in future. The present communication describes the PEC study on Zn-doped α-Fe2O3 thin films prepared at different doping concentrations (0.1M, 0.005M and 0.0025M). Resistivity was found to depend upon the doping concentration of Zn and thickness. For thin film deposition, there are various kinds of deposition methods like Chemical vapour deposition, Spin coating, Thermal evaporation, Dip coating. Spray pyrolysis etc[20-22]. Here we have applied spin coating methods in this research project, which is one of the easiest techniques for preparing thin films [23-24]. In this research Zn:Fe_2O_3 thin films with different doping concentrations were prepared by the spin coating method and doping effects of these films after annealing were also studied. After synthesis Zn:Fe_2O_3 solution is taken by micropipette and drop cast on glass surface then spin coated.

II. EXPERIMENTAL METHODOLOGY

A. SOLUTION PREPARATION FOR DOPING

The p and n-type semiconductor were separately prepared by a simple one-pot spin coating method on ultrasonically cleaned 1x1 inch sizes glass substrates. The substrates were also chemically cleaned with the piranha solution (5:1 H_2SO_4 and H_2O_2 mixing) for the increase of hydrophilic properties in which enhance water-compatibility. After that, the dried substrates with atmospheric air were available for the use.

0.11 M $FeCl_2$ Solution Preparation:

Ethanol	100 ml
$FeCl_2$	1.3943 g

0.01M $(CH_3COO)_2Zn.2H_2O$(Zinc acetate) Solution Preparation:

Ethanol	100 ml
$(CH_3COO)_2$ $Zn.2H_2O$	219.527 mg

when the two solutions were mixed and stirred for 10 minutes. After that Zn doped α-Fe_2O_3 solution had prepared. In this way, 0.005M and 0.0025M Zn doped α-Fe_2O_3 solution had prepared. After synthesizing Fe_2O_3, 5μL of the solution was taken by micropipette and dropped on loaded substrate surface then spin-coated with the following rotational speed and time:

SP1	T1	SP2	T2
500rpm	3s	7000 rpm	30s

B. ANNEALING

Two sets of the sample were annealed after deposition at two different temperature (450^0C & 550^0C) for 4 hours in a thermal annealing furnace (carbolite CWF-1200). Then they were left to be cooled naturally to the room temperature.

C. Studies with Atomic Force Microscope (AFM)

Atomic force microscope (AFM) [25] of model (XE 70) park system was used to study the roughness (nm) [26] of the all film surface.

III. Results & Discussion

A. Resistivity Measurement

The electrical resistivity of Zn:Fe_2O_3 semiconductor measured by using Van der Pauw's technique [27-28]. The resistivity variation of different layer Zn doped α-Fe_2O_3 thin film at different temperature and different molar concentration are shown in the following table:

Table 1: The resistivity variation of different layer at 450˚C temperature with different molar concentration

No. of Layer	0.01M Resistivity (Ω-m)	0.005M Resistivity (Ω-m)	0.0025M Resistivity (Ω-m)
Layer 1	10.8	2.2	1.7
Layer 3	8.0	1.8	1.1
Layer 5	4.0	1.1	0.9

Table 2: The resistivity variation of different layer at 550˚C temperature with different molar concentration

No. of Layer	0.01M Resistivity (Ω-m)	0.005M Resistivity (Ω-m)	0.0025M Resistivity (Ω-m)
Layer 1	8.2	6.0	0.7
Layer 3	7.0	2.9	0.6
Layer 5	7.8	3.1	1.9

It was observed that the resistivity of annealed films increases with temperature. The increase in resistivity was not linear. It was seen that the Resistivity of the films decreased with decreasing the molar concentration.

Resistivity variation of different layer Zn doped α-Fe_2O_3 thin film at a different temperature and different molar concentration are shown in Fig. 1, Fig. 2, Fig. 3

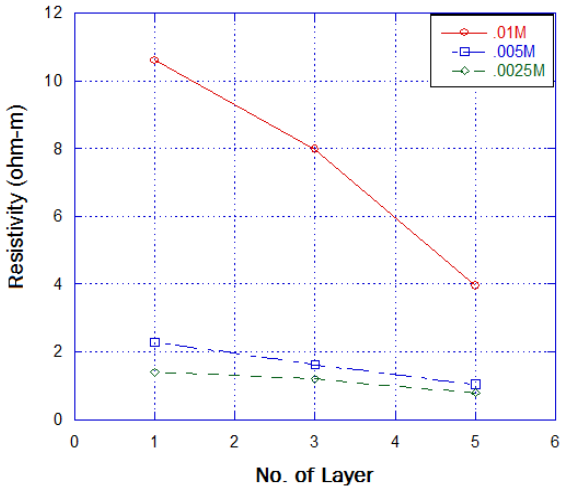

Fig. 1 Resistivity of different molar concentration 0.01M, 0.005M and 0.0025M and different layer at temperature 450˚C .

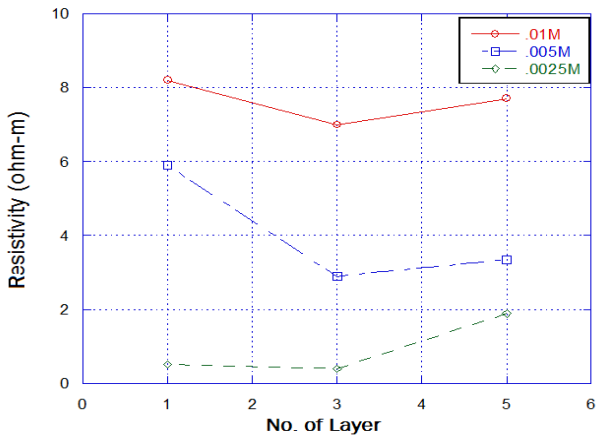

Fig. 2 Resistivity of different molar concentration 0.01M, 0.005M and 0.0025M and different layer at temperature 550˚C .

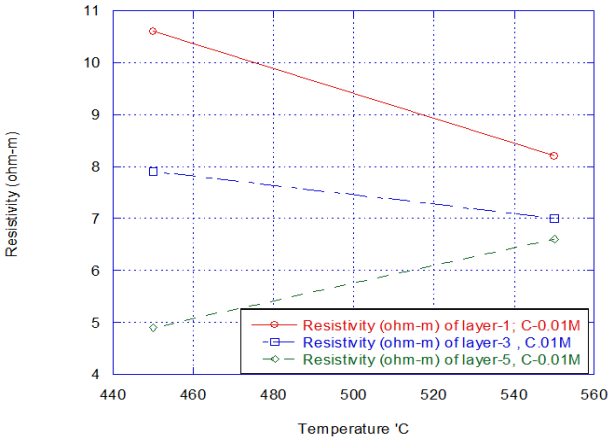

Fig. 3 Resistivity of different layer and different temperature at 0.01M molar concentration

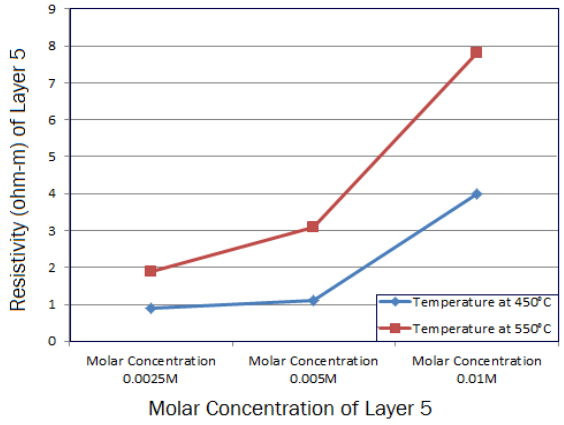
Resistivity at different temperature and different molar concentration in layer 5 as shown in Fig. 4



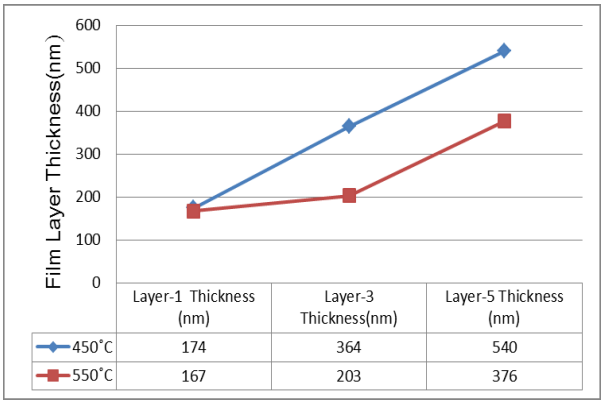


Fig. 4 Resistivity at different temperature and different molar concentration in layer 5.

B. Surface Morphology Study using AFM

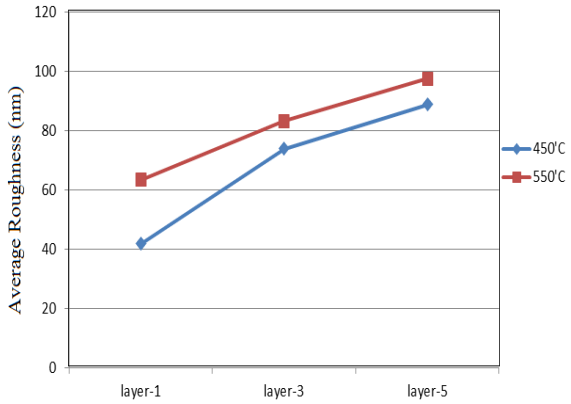
The thickness of the Zn doped α-Fe_2O_3 thin film varied with annealing temperature and a number of the film layer. Following Fig-5 has shown the thickness (nm) variation of Zn doped α-Fe_2O_3 thin film with temperature:

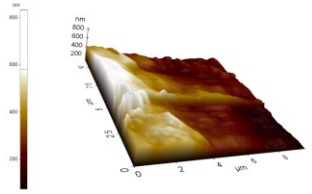
	Layer-1 Thickness (nm)	Layer-3 Thickness(nm)	Layer-5 Thickness (nm)
450˚C	174	364	540
550˚C	167	203	376

Fig-5: Thickness variation of the thin film layer at different annealing.

The thickness of the film has been increased with increasing the number of the film layer and decreased with the increase of annealing temperature. This was due to the fact that increasing of annealing temperature reduces various types of defects like voids, crystal defects and dislocation density.

The relation between annealing temperature & the thin film surface roughness was inversely proportional. Variation of the average value of Roughness of Zn doped α-Fe_2O_3 at 450 ˚C, 550˚C and AFM images are the following:





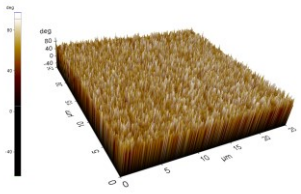


Fig.6: Average value of Roughness (nm) of the film surface of different layer at different temperature of the thin film

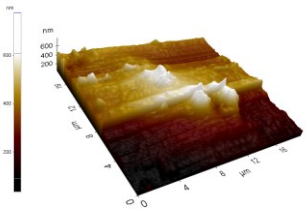
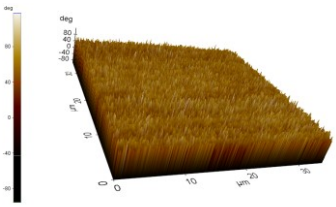


(a)



(b)

Fig. 7 Surface morphology of Zn doped α-Fe_2O_3 Layer 5 at 450˚C near to the Edge (a) and middle of the surface (b)

(a)

(b)

Fig.8: Surface morphology of Zn doped α-Fe_2O_3 Layer -5 at 550˚C near to the Edge (a) and middle 0f the surface (b)

IV. Conclusions

The effect of different parameters (annealing temperature, thickness and molar concentration) on the electrical property of the spin-coated thin film of Zn:Fe_2O_3 on the glass substrate has been investigated. It was observed that the resistivity of annealed films increases with temperature. The increase in resistivity was not linear. It was seen that the Resistivity of the films decreased with decreasing the molar concentration. The semiconductor type was not stable for very long time, their properties were converted from p-type to n-type as well as the carrier concentration were degraded with the time to leave due to their solid format of zinc. But the lightly doped Zn:Fe_2O_3 retained its p-type conduction for comparatively long time. Because lightly doped Zn:Fe_2O_3 can be able to form comparatively highly attraction bond.

It was also observed that the resistivity of the thin film decreases with increasing of film thickness (increasing number of film layer). Films with lower thickness may have defects like lattice defects, voids etc. These defects significantly contribute to resistivity. When the film thickness was increased more atoms are deposited on film surface which reduces the defects (voids, crystal defects [29] and dislocation density[30]) on film. As a result, resistivity decreases.

The surface of Zn:Fe_2O_3 was investigated with atomic force microscope (AFM) to see the effect of annealing on surface roughness. It was observed that the surface roughness and thickness was reduced after increasing the annealing temperature. This was due to the fact that increasing of annealing temperature reduces various types of defects like voids, crystal defects and dislocation density. So the film becomes more smooth which was expected for thin film.

***Abstract*— In this work, a digitalized sol-gel system is prepared for fabrication of efficient thin films. The proposed system of this paper offers dipping and withdrawing of a substrate with precise timing and has an extra feature of holding multiple beakers having multiple solutions for fabricating complex layered films. This system also provides rotation of the beakers containing required solution to be deposited on a substrate with the help of pressing only a button. Duration of dipping time of the substrate can also be set using this system. In short this digitalized system offers multiple features of thin film fabrication using sol-gel technique with high percentage of minimizing defects.**

***Keywords*— Sol-Gel technique, L293D motor driver, DC gear motor, 16*2 LCD.**

I. INTRODUCTION

Thin films have many applications in this modern age like fabrication of electronic components, solid-state devices, microelectronics IC's etc. Films are generally defined by layering a substrate (glass, FTO, plastic etc.) with a solution having the required properties for the purpose of fabricating that film after that the layer on top of the substrate is either heated on rapidly thermal annealed. If the film thickness is less than one micron then the film is called thin film. There are many ways of fabricating a film such as sol-gel dipping, spin-coating, sputtering, spray-pyrolysis, thermal evaporation, CVD, PVD etc. Among them sol-gel technique is not only easier but also cost efficient. By this technique both amorphous and crystalline films can be fabricated [1]. Conventional sol-gel technique was briefly discussed in the year 2002 [2], but that technique was not automatic and requires manual control which is not appropriate for preparing uniform thin films. M. F. Ali, U. Saha and M. F. Hossain designed an automatic length controlled sol- gel system in the year 2012 which can deposit thin film for 2 cm, 3 cm, 4 cm, 5 cm, 6 cm & 7 cm [3], but that system requires the use of ribbon which is very much subjected to vibration and the dipping and withdrawing speed cannot be controlled in that system. Later in the year 2015 Dr. M. F. Hossain and Ayesa Tuz Johra proposed a digital sol-gel system which was designed to solve the problem of using ribbon by using mechanical gear but that was not completely vibration less [4]. Our proposed system has the extra feature of having a beaker carrier and movable position of the horizontal circular surface attaching the beakers. This machine also has less vibration compared to previously designed systems and has fewer defects on the resultant prepared films. By using our proposed system multilayered films can be fabricated as the sol-gel dip coating system is a very useful technique for fabricating & characterizing self-assembled structures & multi-layered thin films [5].

II. DESIGN AND COMPLETE SETUP OF THE PROPOSED SYSTEM

A. Block Diagram

Fig. 1 shows the basic block diagram representation of our proposed digital sol-gel system. The main parts of the digital sol-gel system are dc power supply unit, 3*3matrix keypad, 16*2 LCD unit, motor driver, pulley, belt, lead screw, motion filter, substrate holder and a microcontroller unit which is the heart of the automatic arrangement. DC power supply unit rectifies 220V ac supply into 5V dc which is supplied to various components of the system.

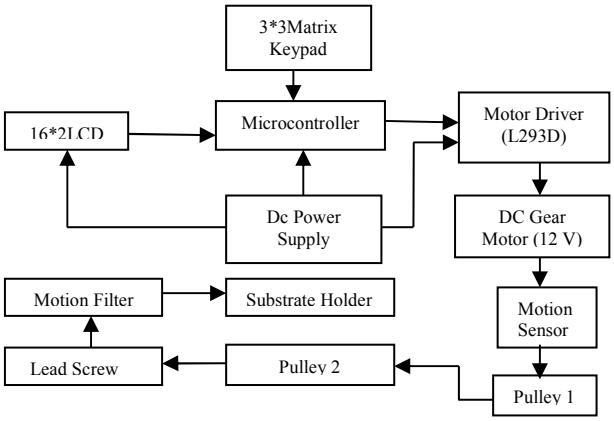

Fig. 1. Block diagram representation of digital sol-gel system.

The dc gear motor used in this work is of 12 V dc bipolar motor. A motor driver a 16 pin IC named L293D has been used. Pulley belt and lead screw mechanism has been used to convert the circular motion of DC gear motor into linear motion and a crocodile clip is connected with the rod which is used to hold the substrate. As a input device a 3*3 matrix keypad and as a display unit a 16*2 LCD character display has been used. After giving input value through matrix keypad microcontroller sends out control signal to the motor driver to drive the DC gear motor. According to the control signal, the DC gear motor starts rotation either in clockwise or anticlockwise direction.

B. Initial Setup of the Automatic Sol-gel System

Initial setup of our proposed system is given in Fig. 2. The total body is covered by steel sheet. The structure of the machine is made with aluminum sheet to increase the stability of the machine. The lower portion consists of the electronics part that is microcontroller, DC power supply unit, motor driver, LCD, matrix keypad, pulley 1, pulley 2, belt etc.

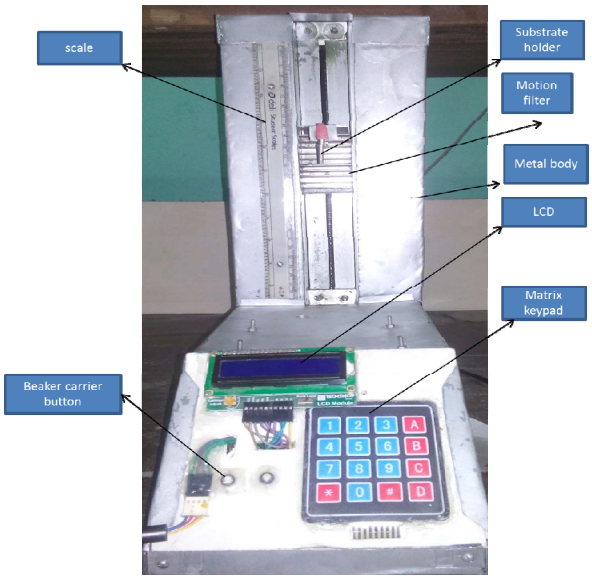

Fig. 2. Initial setup digital sol-gel system (without beaker carrier).

Fig. 3 shows the internal view of the machine. Pulley 1 is attached with the motor shaft and Pulley 2 is connected with pulley 1 by a belt. Then pulley 2 is connected to a lead screw which is placed vertically from lower portion to the upper portion of the machine. A rod (to which the substrate holder is attached) with a screw is attached to the lead screw. So when the lead screw rotates the rod moves upward or downward according to the rotation of the lead screw. Thus the circular motion of the motor shaft is converted to linear motion.

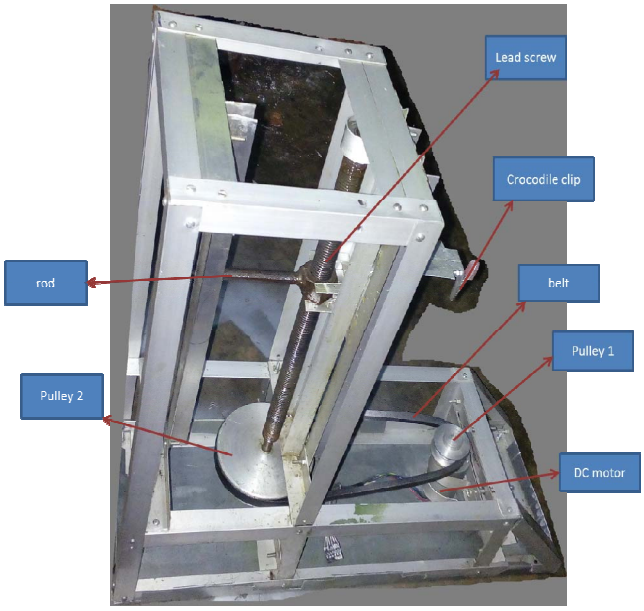

Fig. 3. Internal view of the designed machine.

A motion filter is used to reduce the mechanical vibration when the motor rotates to have a uniform speed of the substrate. The width of pulley 1 and pulley 2 are 1 inch and 3.5 inch respectively. This means that to rotate pulley 2 for one time, pulley 1 has to rotate for three and half times. Now the lead screw has 13 threads per inch. That means when the screw rotates for one time its vertical distance is 1/13 inch. So to have a vertical distance of one inch the lead screw has to rotate 13 times, pulley 2 has to rotate for 13 times, pulley 1 has to rotate for 45.5 (= 13*3.5) times. Thus we can have a very lower speed of the linear motion. The lowest speed that we could achieve is 1 mm/sec.

C. Complete Setup of the System with Beaker Carrier

Suppose we want to have layers of different solution on a substrate or layer of different solution on different substrates. So we will have beakers of different solutions. We can't place several beakers on the beaker base and every time we have to change the beaker manually to have layers of different kind of solutions on the substrate. To remove this problem an additional feature I have made which is the smart beaker carrier. We can see it in Fig. 4 (a), it contains four sections to place four beakers on it. And with a press on the button associated for the beaker this beaker carrier can rotate clockwise. It rotates 90 degree at a time and consequently we can place our required beaker underneath the substrate holder among the four beakers. A stepper motor is used to have the circular motion of the beaker carrier.

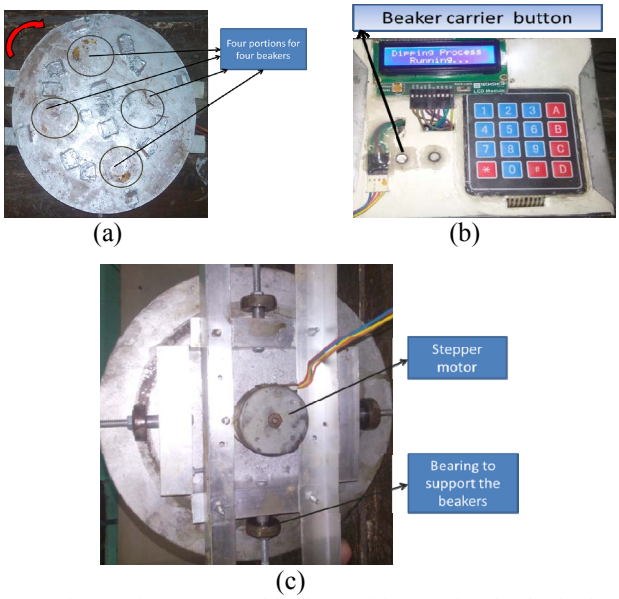

Fig. 4. Beaker carrier: (a) No. of beaker position on the circular beaker carrier, (b) Beaker carrier button & (c) Bearing and motors of the beaker carrier.

Fig. 5. Final setup of the digital sol-gel system (with beaker carrier).

The stepper motor of the beaker carrier takes power from the switch placed in front of sol-gel machine. Now if we wish we can use the beaker carrier or we can do the dipping process without it. There are four bearings under the base of the beaker to support the four beakers placed on it which is shown in Fig. 4 (c). The base is mounted with the shaft of the stepper motor. When the motor rotates the beaker carrier rotates clockwise for 90 degree at a time when we press the button. The final setup of our proposed system is shown in Fig. 5.

III. Operating Principle of Digital Sol-gel System

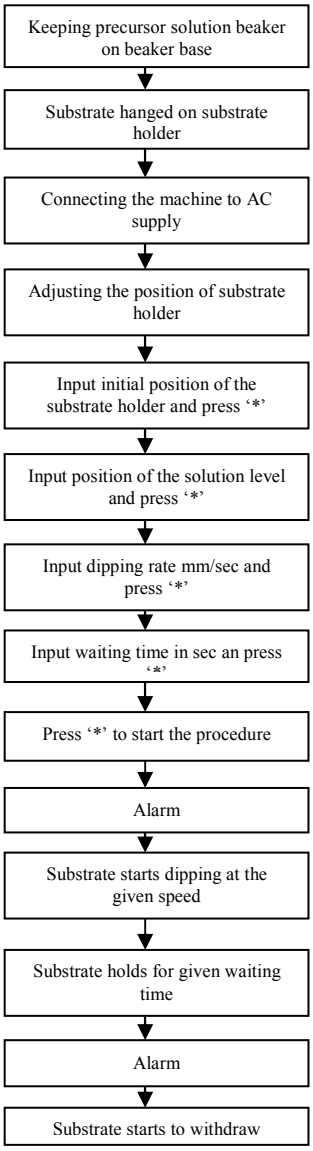

Fig. 6. Operating principle of the proposed system.

The operating principle of digital sol-gel system is shown in Fig. 6 which is basically a block diagram. At first prepared precursor solution is kept on the beaker base and a clean substrate is hanged on the substrate holder. Then the machine plug is connected to the Ac line. After making the primary setup, power switch is turned on and a message "Welcome to Nano Lab of Ruet….Automatic sol-gel machine" comes out on display. After 2 sec a message "press '*' to Start, A or B to adjust" comes to display and we can adjust the position of the substrate holder. Then a massage "Input Initial Position" comes out on display and we have to input the initial position of the substrate holder. Then a massage "Input Solution Level" comes out on display and we have to input the solution level. After that a massage "Input DIP Speed" comes out on display and we have to input the required dipping speed of the substrate. Then a massage "Input Waiting Time" comes out on display and we have to input the desired waiting time before withdrawing the substrate. There must not to be made hurry while pressing two keys one after another. Because intentionally there have been made a delay of 0.5s between two keys pressing for programming purpose.

After correctly giving all of the input values from keyboard the motor starts to rotate in anticlockwise direction to move the substrate in downward direction at a rate of given rpm. And a message "dipping process running" comes on display. After completing the dipping length the substrate wait in the solution for a given waiting time. Then it starts to withdraw at a given rpm and when it reaches to a predetermined position it closes an alarm switch and alarm sound is heard and a message "Thank you" comes on display and the current operation breaks down. Then the digital sol-gel system goes to the start position and is prepared for another operation.

IV. Results and Discussion

To examine the results of the proposed digital sol-gel system we prepared ZnO thin film using this machine. Images of different lengths of substrates covered by ZnO thin films that have been deposited by proposed digital sol-gel process is shown. All the prepared films have been characterized by optical properties with UV visible spectrometer in the wavelength range of 300-900 nm. Fig. 7 show the images of ZnO films prepared by length variation by proposed digital sol-gel process. It can be easily figured out that the proposed digital sol-gel system is successful in depositing ZnO thin films on the required length of substrate without any problem. It is also clearly shown that the surface of prepared films has been grown uniformly.

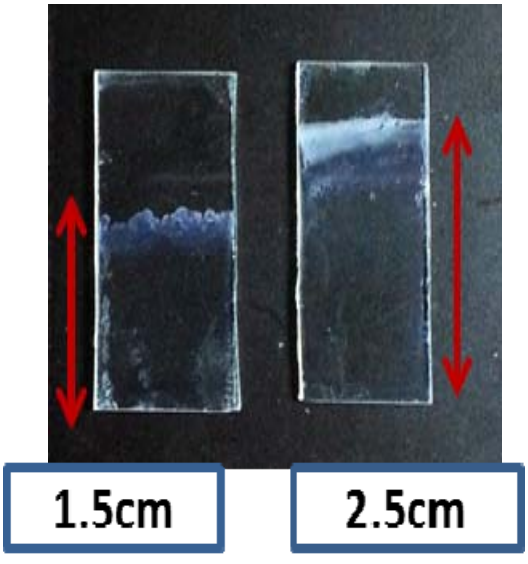

Fig. 7. ZnO thin film by length variation.

Fig. 8 shows the optical transmittance spectra of the prepared film of length 2.5cm. The film has a very sharp cut-off at around 375 nm wavelength and reaches to peak at around 400 nm.

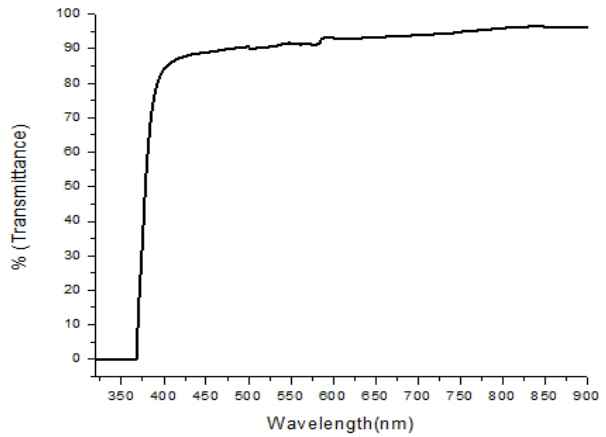

Fig. 8. Transmittance spectra of ZnO thin film (2.5cm) made by proposed machine.

According to Tauc's law relation between absorption co-efficient (α) on photon energy (hν) can be written as [6]:

$$\alpha h\nu = A\left(h\nu - Eg\right)^{m} \quad (1)$$

where, $m = \frac{1}{2}$ and 2 for direct and indirect transitions respectively. α is known as absorption coefficient, A is defined as the edge width parameter and hν is called the photon energy. Fig. 9 shows the curves of $[\alpha h\nu]^2$ vs. photon energy hν for direct band gap transitions of ZnO thin film.

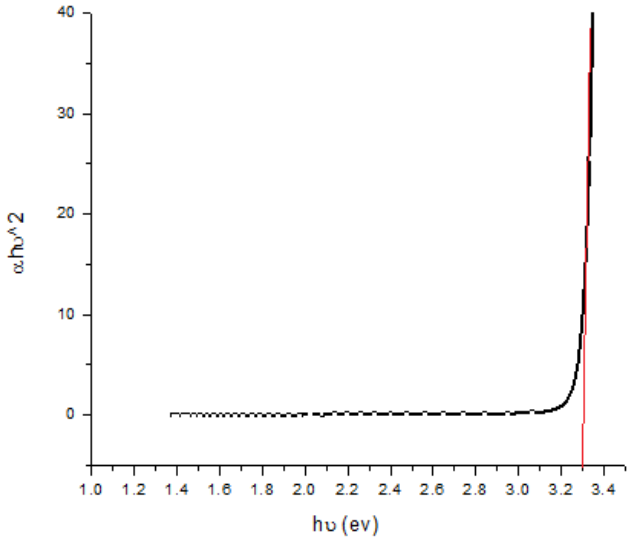

Fig. 9. The curve of $[\alpha h\nu]^2$ vs. photon energy hν for ZnO thin film (2.5cm).

V. Conclusion and Future Work

The work reported in this paper is mainly focused on development of a new user friendly automatic sol- gel system and after that preparation of ZnO thin film for result verification of the system. Starting with aim of the work, first the limitations of existing digital sol-gel system were identified. In spite of the higher cost the new system overcomes the limitations of existing systems to a great extent. Lastly ZnO thin film was prepared successfully by length variation. And prepared films were characterized with respect to optical property (transmittance, absorbance, direct bandgap) by using UV visible spectrophotometer for 300-900 nm. This paper represents the modeling of a new automatic sol-gel system. The prepared ZnO can be used for various applications like transparent conductive oxide, UV detector, optical window, DSSC solar cells, waste water purification, air purification etc. Future directions related to the work in this thesis are improving the modeling of substrate holder more substrate can be deposited at a time, to achieve more lower speed of the substrate up to 1cm/min.

Acknowledgement

For this work the authors of this paper is very much thankful to Rajshahi University of Engineering and Technology (RUET) for giving them the opportunity to use Nanotechnology and Photovoltaic's lab for successful outcome of this experiment.

***Abstract*—In this paper, we demonstrate a highly sensitive Kretschmann configuration based surface plasmon resonance (SPR) biosensor with high detection accuracy (DA) and quality factor (QF). Five layers of biosensor model is proposed using numerical simulation and graphical analysis. In this model, graphene and heterostructures of black phosphorus improve the sensitivity of biosensor. Silver (Ag) is coupled with prism CaF_2 for better reflectivity, since CaF_2 has the less refractive index (RI). The mentioned model gives the highest sensitivity for 633 nm wavelength p-polarized light is 263.51 °/RIU with higher detection accuracy (DA) 2.14 and quality factor (QF) 57.915 RIU^{-1}.**

Keywords—Surface plasmon resonance, Sensitivity, Biosensor, Detection accuracy, Quality factor.

I. INTRODUCTION

In this contemporary age, optical sensors become a preferable phenomenon due to its enriched accuracy, better sensitivity, low cost and inferior bulk [1]. These sensors are mainly classified into two types based on fiber optics and optical free space. Hence surface plasmon resonance (SPR) is considered as optical free space sensors [2]. Due to the accelerated progression of SPR optical technology, it has become a promising platform for photonics, optoelectronics and biosensors [3]. SPR is a technology which appears at the metal-dielectric surface at the time of light reflects at a SPR angle and due to metal (noble metal nanoparticles, Al nanoparticles, conventional semiconductors and 2D materials) surface conditions, there occurs an intense change of reflected light [4]. SPR based on optical sensor, which is one of the most impressible methods for the biomolecules detections by resonance and it is a physical process under reflection conditions [5]. In practical life, SPR sensors are convenient with various applications such as organic chemical sensing, gas detection [6], food quality maintaining, monitoring glucose, molecule detection, [7] environment monitoring and digital devices like as smartphone platforms or clinical diagnosis [8]. Especially, biosensors technology in the biomedical area has drawn a wide sight in research field such as haemoglobin concentration, toxicology and in microbiology [9]. In conventional SPR biosensors that had less competency of sensing small biomolecules like virus, bacteria and DNA for the low coalition onto the metal surface [10]. Therefore, this limitation can be exhibited by several gateway where mixing a core-shell of nanoparticle metal acting as the effective material over the conventional biosensors [11]. For enhancing the sensitivity of biosensor, hetero-structures and transition metal di-chalcogenides (TDMC) are more preferable with two dimensional (2D) material such as graphene layers. Those TDMC (MoS_2, $MoSe_2$, WS_2, WSe_2) have distinctive electrical and optical properties and graphene has high carrier mobility, better optical transparency, strength and flexibility [12]. Graphene aids biomolecule adsorption for their wide surface area and due to high π conjugation, preferring compatible dielectric top layers in SPR bio-sensing [13]. Wu et al. proposed a model where they had used graphene coated biosensor for enhancing sensitivity in SPR [14]. Since 2014, black phosphorus has become new promising 2D materials for its direct band gap, better carrier mobility, enrich electrical and optical properties [15]. Qiao et al. showed a few layer black phosphorus based model with polarized light for attaining high mobility [15]. Other materials such as Silver (Ag), Gold (Au), Cobalt (Co), Aluminum (Al), Copper (Cu) are also well known in SPR sensing model and have a better oxidization with good corrosion behavior in biosensors [14]. For better sensing model, BK7, CaF_2, SF10 prism glasses are very popular but among them, CaF_2 has the minimum refractive index which has a tremendous effect on sensitivity [16, 17]. Herminjard et al. circumstantiated the sensitivity of CaF_2 as a prism glass [17] and Shushama et al. presented graphene coated BK7 glass based SPR sensor [16].

Finally, in this paper we have proposed a modified and standard Kretschmann arrangement for a SPR based biosensor utilizing Silver (Ag) layers, black phosphorus (BP) and graphene layer with CaF_2 prism glass. Using MATLAB simulation with transfer matrix, we have been carried out highest sensitivity for graphene coated CaF_2 glass.

II. NUMERICAL MODELING AND DESIGN CONSIDERATION

For SPR technology, two configurations Otto and Kretschmann are preferred in most of the research but Kretschmann is more suitable for coupling prism with metal film layers[18]. The proposed final SPR biosensor is analyzed using five-layers structure with 633 nm wavelength and represented in Fig.1. This operating p-polarized 633 nm red laser is taken for developing the optical nonlinearity for specific frequency. Here we have applied the transfer matrix method and Fresnel equations founded on N layers structure which calculate the reflectivity of the reflected light [16] and due to having no approximation this method is the most efficient. Along with the Z-axis the thickness of the layers dk are considered and the refractive index (RI) of kth layer and dielectric constant are considered as ek and nk. The fields of tangential at first boundary $Z=Z_1=0$ are related with term of the final tangential boundary field at $Z=Z_{N-1}$ [19].

$$\begin{bmatrix} p_1 \\ Q_1 \end{bmatrix} = M \begin{bmatrix} P_{N-1} \\ Q_{N-1} \end{bmatrix} \tag{1}$$

Here P_1 and Q_1 are the element of electric and magnetic fields at the tangential boundary of the first layer and P_{N-1} and Q_{N-1} are the boundary field at N^{th} layer where characteristic matrix is M with Mij [14].

where,

$$M_{ij} = \left(\prod_{K=2}^{N-1} M_K\right) = \begin{bmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{bmatrix} \tag{2}$$

$$M_K = \begin{bmatrix} \cos\beta_K & (-i\sin\beta_K / q_K) \\ -iq_K \sin\beta_K & \cos\beta_K \end{bmatrix} \tag{3}$$

$$q_K = \sqrt{\frac{\mu_K}{e_K}}\cos\theta_K = \frac{\sqrt{(e_K - n_1^2 \sin^2\theta_1)}}{e_K} \tag{4}$$

$$\beta_K = \frac{2\pi d_K}{\lambda}\sqrt{(e_K - n_1^2 \sin^2\theta_1)} \tag{5}$$

The reflection intensity for p-polarized light with reflection coefficient and reflectivity are expressed as,

$$r_p = \frac{(M_{11} + M_{12qN})q_1 - (M_{21} + M_{22qN})}{(M_{11} + M_{12qN})q_1 + (M_{21} + M_{22qN})} \tag{6}$$

$$R_p = \left|r_p\right|^2 \tag{7}$$

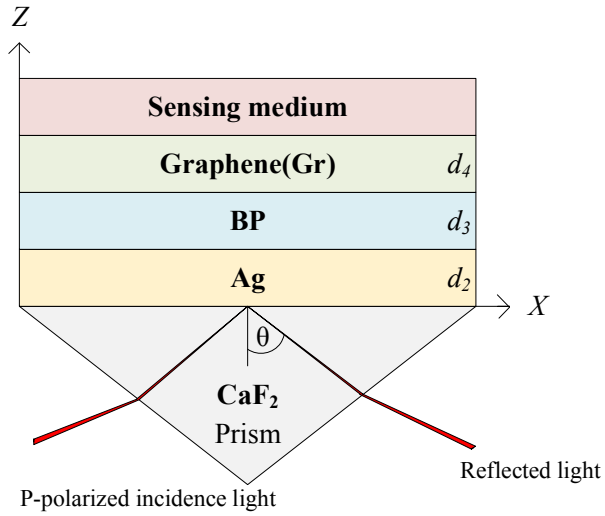

Fig. 1. Schematic structure of the proposed SPR biosensor.

In Fig. 1, proposed five layers SPR sensor has one prism glass of CaF_2 act as first layer and thickness of the metals are described as d_2, d_3 and d_4: silver (Ag) as the second layer, black phosphorus (BP) as the third layer, graphene (Gr) as fourth layer and at last sensing medium layer.

III. REFRACTIVE INDEX FOR VARIOUS LAYERS

In this proposed structure, CaF_2 glass has been applied instead of other glasses (BK7 or SF10) for enhancing the sensitivity with the combination of other consecutive layers because of holding a comparatively lower refractive index. The RI of the prism glass can be calculated by the according equation with λ = 633 nm [23(16)].

$$n_x = \sqrt{\left(\frac{1.03961212\lambda^2}{\lambda^2 - 0.00600069867} + \frac{0.231792344\lambda^2}{\lambda^2 - 0.0200179144} + \frac{1.03961212\lambda^2}{\lambda^2 - 103.560653} + 1\right)} \tag{8}$$

According to Drude-Lorentz model, refractive index of proposed metals can be calculated as follow [23(16)],

$$n_m = \sqrt{\left[1 - \frac{\lambda^2 \lambda_C}{\lambda_P^2(\lambda_C + i\lambda)}\right]} \tag{9}$$

Where λ_C and λ_P are the collision and plasma wavelengths. After the calculations, the refractive indexes are Ag = 0.8-4.2346i and BP = 3.5-0.01i respectively. The RI of graphene in complex form is developed as $n_4 = 3 + \frac{C}{3} i\lambda$ (λ = wavelength of vacuum and $C \approx 5.446$ μm^{-1}) [23]. Here the RI of sensing medium is $n_5 = 1.33$.

IV. SENSITIVITY AND RESONANCE ANGLE OF BIOSENSOR

Sensitivity (S) is the most vital element for evaluating the performance of a biosensor. It is determined by the ratio of change in the resonance angle ($\delta\theta$) and RI chance in sensing medium (Δn_s) [16].

$$S = \frac{\delta\theta}{\Delta n_s} \tag{10}$$

The resonance condition can be expressed as below. [16(11)],

$$\frac{\omega_o}{C} n_x \sin\theta_{SPR} = \frac{\omega_o}{C}\sqrt{\frac{\varepsilon_m n^2 d}{\varepsilon_m + n^2 d}} \tag{11}$$

Where $\sin\theta_{SPR}$ is the resonance angle in prism with RI n_x, Real part of metal permittivity is ε_m and n_d is RI of sensing medium or dielectric metal. and an incident light beam for propagation constant is ratio of ω_o and C (ω_o = frequency of light and C = speed of light).

The direction accuracy is figure out by the ratio of change in resonance angle ($\delta\theta$) and the full width at half maximum (FWHM) of reflectance curve follow. The FWHM should be low for high accuracy [20].

$$DA = \frac{\delta\theta}{FWHM} \tag{12}$$

Finally, quality factor (QF) is the sensitivity of biosensor to FWHM ratio [12].

$$QF = \frac{S}{FWHM} \tag{13}$$

V. Results and Analysis

In this paper, we have simulated various kind of response curve for the proposed structural SPR biosensor. For simulation, the transfer matrix procedure is used and the design is modified by the Kretschmann configuration. The highest sensitivity is obtained by considering first performance parameter then considering the relationship of RI with resonance angle and sensitivity and finally, optimized the different layers of the thickness of various metals we used. The five-layers model contains CaF_2 (prism), Ag, BP and graphene. The basic performance of SPR biosensor can be obtained by reflectivity, with respect to angle of incidence at changeable RI. When p-polarized light incidence on prism then the surface is excited of the SPR. Then a sharp dip is analyzed at an appointed angle. This phenomenon is happened due to a change in the RI for an accordance of molecule interaction in the sensing surface of biosensor [26].

A. Determination of performance parameter

In performance determination, the values of RI are used for simulation taken from the aforementioned section and at first considering the prism with Ag (28 nm) and got 222.97 °/RIU sensitivity in absence of BP and graphene layers. For this configuration, the quality factor (QF) and detection accuracy (DA) are obtained 68.61 RIU^{-1} and 2.538 respectfully. Now, considering Ag (28nm) and BP (2×0.53 nm) layers with the prism in absence of graphene layers and got the highest sensitivity of 258.10 °/RIU with QF = 52.14 RIU^{-1} and DA = 1.931. Here the thickness of BP layers is obtained by the equation L×0.53 nm. Where number of the layers is L . When only BP is absent and graphene layers are taken by L×0.34nm, then the sensitivity is decreased for the effect of graphene and obtained a sensitivity 237.63 °/RIU, QF = 65.16 RIU^{-1} and DA = 2.412.

Finally, the proposed model with Ag (28 nm), BP (2× 0.53 nm), graphene (1×0.34 nm) shows the highest sensitivity 263.51 °/RIU among all the model and QF = 65.16 RIU^{-1} and DA= 2.412. The highest sensitivity curve for the proposed model is figured out in Fig .2.

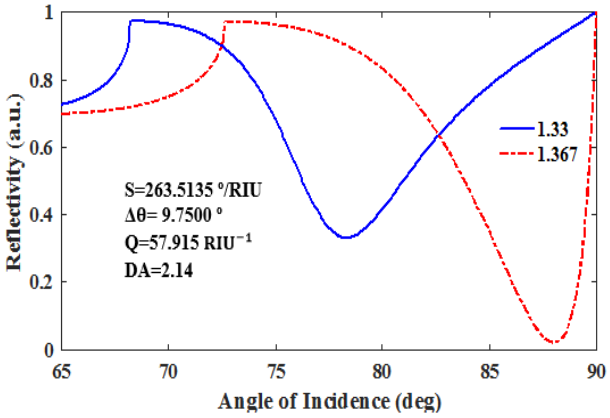

Fig. 2. Reflectivity versus angle of incident at highest sensitivity.

The circumstance above, points out the implication of change in RI for attaining highest sensitivity in the SPR biosensors. Table.1 reported the above discussion with a suitable comparison.

TABLE I. SENSITIVITY, QF AND DA COMPARISON FOR DIFFERENT CONDITIONAL MODEL.

Ag (1) nm	BP (0.53) nm	Gr (0.34) nm	Sensitivity (°/RIU)	QF= (S/FWHM)	DA=(δθ/FWHM)
28	0	0	222.973	68.614	2.538
28	2	0	258.10	52.143	1.931
28	0	1	237.63	65.162	2.412
28	2	1	263.51	57.915	2.144

B. RI with resonance angle and sensitivity

For the minimum change in RI, the resonance can be drastically changed. For analyzing better sensitivity, mostly high resonance angle is preferred. So the higher resonance angle, the better it responses in shortest change of RI. Fig. 3 shows the relation curve between resonance angle and different RI with metal configurations.

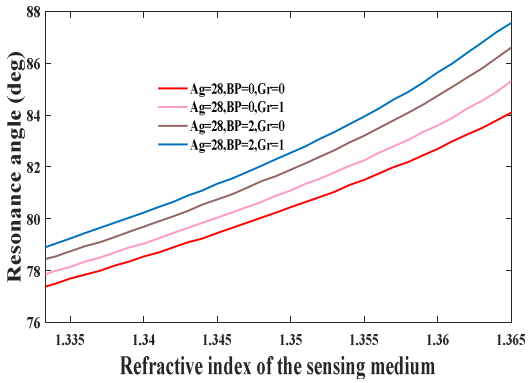

Fig. 3. Curve plotting for resonance angle versus RI of medium.

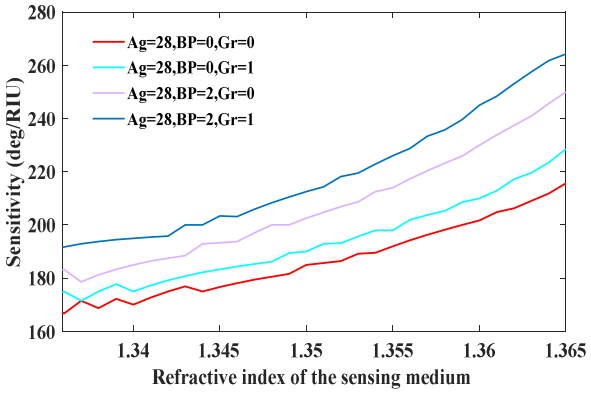
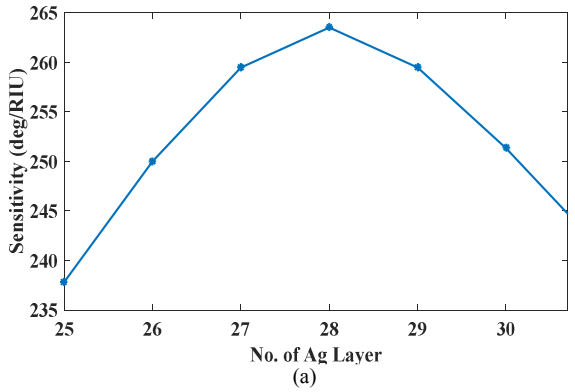
Finally, in Fig. 4 the relation curve for the sensitivity versus refractive index is plotted and the highest sensitivity is gained at 1.3670 for the proposed configuration. In simulation, the maximum RI change is considered in the range of 1.3300 to 1.3700.





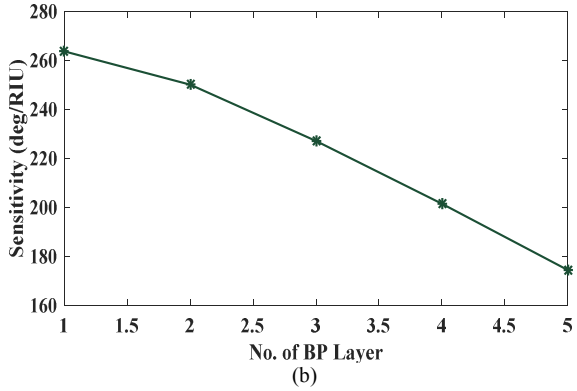


Fig. 4. Sensitivity versus RI of the medium.

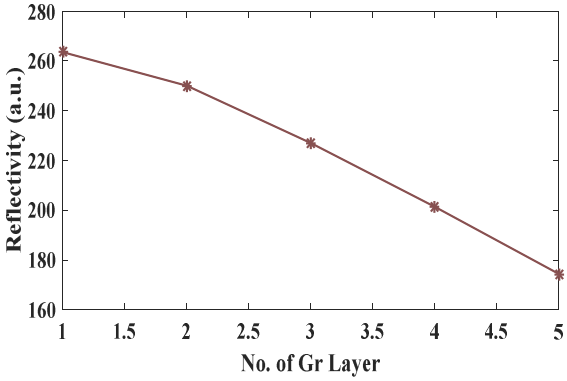
C. *Optimization of different layers thickness*



Obtaining the highest sensitivity with Ag layers, Fig. 5(a) is analyzed. Which represents the condition between sensitivity and thickness of Ag layers and for the thickness 28 nm the highest sensitivity 263.51 °/RIU is attained. In the Fig. 5(b), the curve for BP layers is plotted and for L = 2 layers highest sensitivity is achieved and by decreasing or increasing from L =2, the value of sensitivity is decreased. Finally, in Fig. 5(c) the layers optimization of graphene is detailed and for the increasing of graphene layers, sensitivity is decreased. So, the highest sensitivity 263.51 °/RIU is attained for the L =1 layer of graphene.

Proposed	Prism/Ag/BP/Gr	633	263.51

A polished comparison among the sensitivity is formed based on previous analogous works of biosensors for prism based SPR model which is precised in Table.2 From the table it is accomplished that the proposed biosensor ensures the highest sensitivity than the prior reported works.

VI. CONCLUSION

The proposed biosensor based on graphene coated layer with Ag and BP offers the highest sensitivity among the previous models. The highest sensitivity 263.51 °/RIU is obtained by optimizing prism, metals, the thickness of layers and RI. This highest sensitivity has also the highest DA about 2.14 and QF about 57.915 RIU^{-1}, which are the parameter for accomplishing the performance of the biosensor. So, a good SPR biosensor must have high sensitivity and better detection accuracy. In the conventional model, graphene is normally coupled with gold (Au) but in this model we have used BP to enhance the sensitivity response. A long range of RI is used for ensuring the perfect highest sensitivity of the biosensor and this biosensor can be used in multiple purpose of biomedical and optics such as DNA hybridization by proper orientation between Adenine (A) and Thymine (T) or between Guanine (G) and Cytosine (C) with match and miss-match monitoring.

***Abstract*—This paper deals with wireless power transmission technology. A battery of an electronic device will be charged wirelessly. The solar panel converts the sun light into electrical energy. Power from a solar panel is sent through a transmitter circuit and received by a receiver circuit wirelessly based on Faraday's law of induction. As magnetic resonance coupling is more efficient and useful than magnetic inductive coupling, in this paper, magnetic resonant coupling is used. There are a transmitter and receiver coil. The transmitter coil is driven at the same frequency of the resonant frequency of the receiver coil. For those reasons, the LC tuned circuit has been built to maintain the same frequency. As power is transmitted wirelessly, some power is wasted. As a result, efficiency is decreased to only 11 %. After all, it will be a future charging solution in the modern world. With the help of wireless battery charger technology, power can be supplied to the electric cars, drones, hospital's equipment, and smartphones. This device also helps to reduce the necessity of using wires.**

Keywords— copper coil, inductive coupling, receiver coil, resonant, solar power, transmitter coil, wireless battery charger.

I. Introduction

Solar energy is a very environment-friendly power source and one type of renewable energy. Besides that, the charge controller makes it more efficient for use as it gives the necessary maximum power to the battery or appliances. Solar panel uses photovoltaic cells that convert light energy from the source of light into electricity. This renewable energy can be used for various purposes, i.e. to run the home appliances, to operate machines and motors. In this study, solar power is used to charge batteries wirelessly. Wireless power transmission system follows the rules of inductive coupling by Faraday's laws. Where transmitting power is converted into high frequencies AC current that is sent to a transmitter coil for which magnetic field is created. The same magnetic field produces current within the receiver coil. This current is converted into usable DC current. Normally wired charger charges batteries but some devices such as, electric toothbrush which is not suitable for a wired charger. Mobile phones can also be charged by wireless, charger station can offer this type of feature.

The solar or photovoltaic system is a very effective energy resource that has established a great impact on the society and industries. In remote areas, it is quite difficult for people to charge their devices because of unavailability of electricity. With this proposed system, it is possible to charge any device without electricity. In this study, an inductive coupling has been used which creates a magnetic field between two objects and transfers energy from source to receiver. With this energy, the battery can be charged without any physical connection.

II. Literature Review with in-Depth Investigation

Transmitting power through a wireless system was invented by Faraday. His research was about current conduction in the wire. If current flows through one wire of a conductor then another wire near to it will gain some current as well. For this, the second wire has to be placed very near to the current carrying wire. This principle was developed by Tesla who built towers to transmit power through the entire world. But the project was unsuccessful because his sponsor discontinued providing financial support for the transmission. The reason for this was, the experiment results were not satisfactory [1].

Many research work has been done for wireless power transmission. A wireless sensor network along with a charging car can increase the lifespan of a network with the help of wireless power conversion technology. The wireless energy can be radiated in every direction as well as a specific direction. So, the charging model can be divided into two model, point-to-point and point-to-multipoint [2]. An ideal case was first mentioned by assuming zero traveling time for the charger. A provably near-optimal solution was obtained based on the discretization and logic point representation techniques. Finding the shortest Hamiltonian cycle helps to discover the moving path of the original problem.A feasible solution is derived with this moving path [3]. Research had been done in the same field and the proposed device's efficiency was very high [4]. In a project named "Automatic wireless mobile charger", the researchers tried to develop a better device to deliver power wirelessly [5]. One more study states that mobile will be charged automatically and wirelessly through radio frequency harvesting [6]. The demand for fossil fuel is increasing day by day. An electric vehicle, developed by wireless technology can lessen the use of fossil fuel [7]. A wireless remote control sysem is applied for protection of the linear generator where the electrical power is supplied from a solar panel connected with a battery and a charger [8]. Another automatic portable grass cutter machine is proposed in which a solar panel, a charger and a battery are used for power supply [9].

In recent years, it has been proved that electricity can be transferred at a distance of about two meters. The efficiency of this technology is 40% where 60% power was wasted. Later, the efficiency has been improved [5].

III. Methodology and Modeling

Wireless power transmission means transferring power without physical wire. Transmission is possible for inductive coupling. The system implementation is done in two parts, one is transmitting side and another one is receiving side.

Firstly, solar array takes energy from the sun. Then, this DC power goes to maximum power point tracking (MPPT). Secondly, MPPT looks at the output of the panels and compress it to the battery voltage. Actually, it figures out what is the best power that the panel can put out to charge the battery and converts received voltage to the best voltage to get maximum ampere into the battery. Thirdly, maximum DC power goes to the wireless charger circuit. In there, wireless battery charging uses an inductive or magnetic field between two objects. At the receiver end, a typical battery is connected. Finally, the battery will be charged. Part by part implementation has been described below.

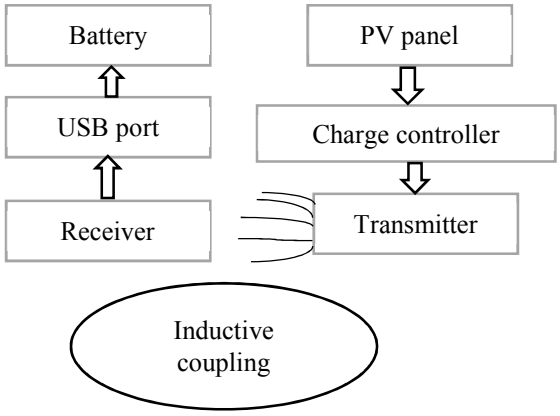

Fig. 1. Block diagram for wireless battery charger.

A. *Transmitter Side*

Transmitter side is comprised of IC 555 timer, general purpose transistor BC547, n-channel MOSFET IRF540N, some capacitors, some resistors, and a tuned LC circuit. This tuned LC circuit is also called the tank circuit.

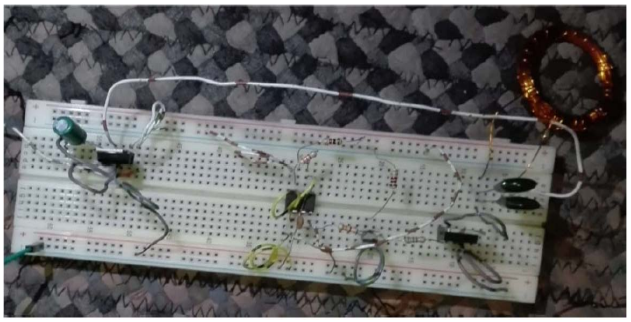

Fig. 2. Design of a transmitter circuit for this system.

B. *Solar Setup for Power Supply*

During the hardware implementation portion, a storage device is required to store the produced energy by photovoltaic cells.

(a) (b)

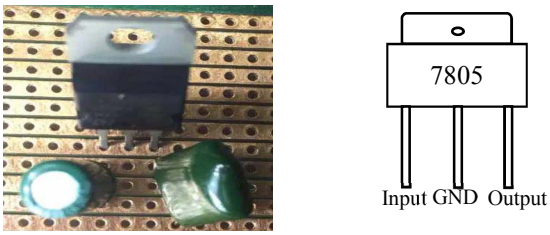

Fig. 3. (a) Measurement of open circuit voltage, (b) measurement of short circuit current.

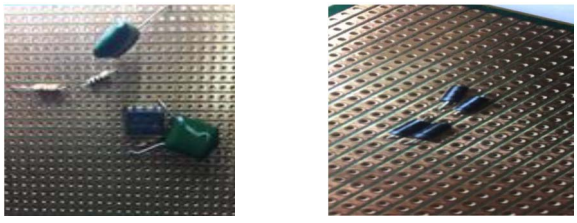
A battery is a common storage device which is used to store electrical energy produced by photovoltaic cells. To charge a battery by using a solar PV, a charge controller is an important device. Therefore, it will be necessary to connect a charge controller in series between the solar panels and the battery.

C. *Setup of Voltage Regulator*

The voltage regulator IC 7805 maintains a constant voltage output for fluctuating of an input voltage and the output voltage is +5 volt. It has 3 pins. Pin number 1 is for input, pin number 3 is for output and pin number 2 is for ground. In this system, pin number 1 is connected with the source as well as a capacitor C5. It is also connected with the tuned LC circuit.

Pin number 2 is connected with capacitor C5 and C6 and then connected with the ground. Pin number 3 is connected with capacitor C6 and also connected with IC 555 timer through its pin number 4.



(a) (b)

Fig. 4. (a) Voltage regulator setup, (b) voltage regulator IC.

D. *Setup of IC 555 Timer*

This is an integrated circuit which is used for pulse generation purpose. There are three types of moods of a timer IC, i.e. Astable, Monostable, Bistable. In this system, Astable mood is used. It puts out a continuous spectrum of rectangular pulses. Each pulse has a specified frequency.

In this system, pin 1 is grounded. Triggering pin 2 is shorted with pin 6 and also connected with a capacitor C6. A transistor is connected with resistor R3 and pin 3. Pin 4 is connected with pin 3 of voltage regulator IC 7805. A grounded capacitor C4 is connected with controlling voltage pin 5. The threshold pin 6 and discharging pin 7 is connected through a single register R2. Pin 8 is shorted with 4.

(a) (b)

Fig. 5. (a) Setup of IC 555 timer, (b) rectifier setup of the system.

E. *Tuned LC Circuit* (*transmitting end*)

The tuned LC circuit is made with capacitors C1 and C2. An inductor is parallelly connected with C1 and C2. This inductor is made with 45 turns of copper wire. The diameter of copper coil is 7.3 cm. This circuit acts as a load circuit. It determines the frequency of oscillation. For this tuned circuit, both the transmitter and receiver circuit is inductively coupled. A voltage is induced at both transmitter and receiver circuit.

F. *Receiver End*

Transmitted oscillating induced voltage from the magnetic field is received here. The induced voltage is used to charge the battery. In the receiving part, some equipment are used such as LC tuned circuit, a current regulator IC MC34063, Schottky diode 1N5819, and some passive equipment.

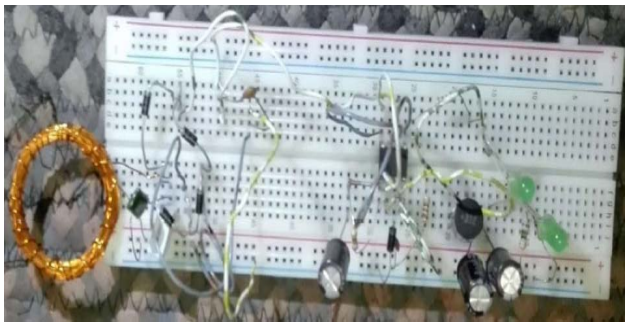


Fig. 6. Receiver side of the proposed system.

G. *Tuned LC Circuit* (*receiving end*)

An inductor made of 50 turns of copper wire is parallelly connected with two capacitors C7 and C8. Rotating magnetic flux comes over this copper coil. This coil is assembled with 7.3 cm in diameter.

(a) (b)

Fig. 7. (a) Copper coil for transmitting end, (b) Copper coil for receiving end.

H. *Setup of Bridge Rectifier*

A bridge rectifier is made with 4 diodes. Tuned LC circuit is connected with the rectifier. This bridge rectifier extracts DC current from the rotating magnetic field. The rectifier is connected with C9 capacitor. Here, DC voltage is ripple free for that capacitor. Rectifier setup has been shown in Fig. 5(b).

I. *Setup of IC MC34063*

This IC is a buck/boost converter. In this system, it works as a buck converter.

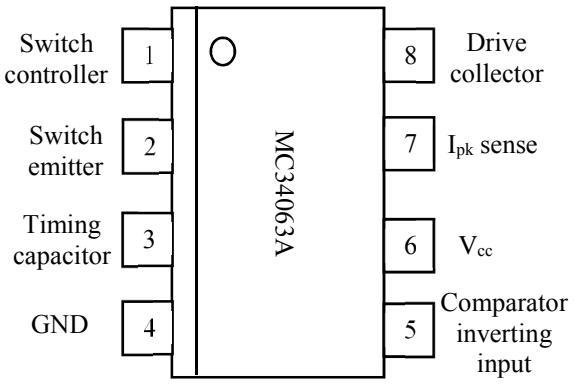

Fig. 8. Buck-boost converter IC.

Buck converter helps to maintain the adjustable voltage and current. Switch collector pin 1 is shorted with driver collector pin 8 and I_{pk} pin 7, then the common point of them is connected with resistor R8. Switch emitter pin 2 is connected with a diode and an inductor. Then, the other parts of the inductor are connected with two capacitor C12 and C13. A load is connected with this common point of two capacitors.

IV. Software and Hardware Interface

Transmitter side is assembled with a solar panel, two IC, transistors, and some other passive devices. The receiver side is assembled with a rectifier, one IC and some passive components. The range of source voltage should be 06 volt to 20 volts. And current should be maintained up to 1 ampere.

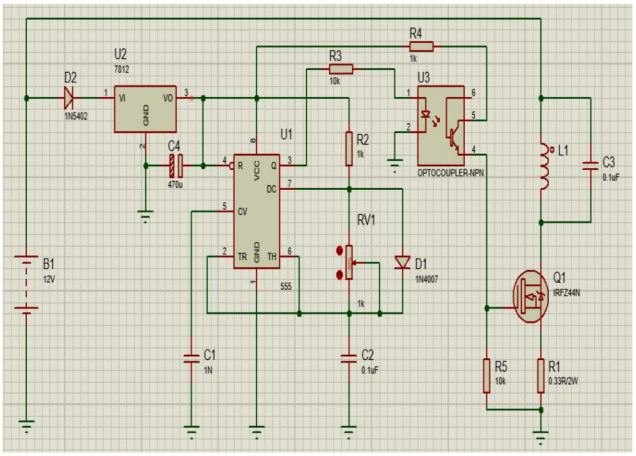

Fig. 9. Circuit diagram for transmitter side.

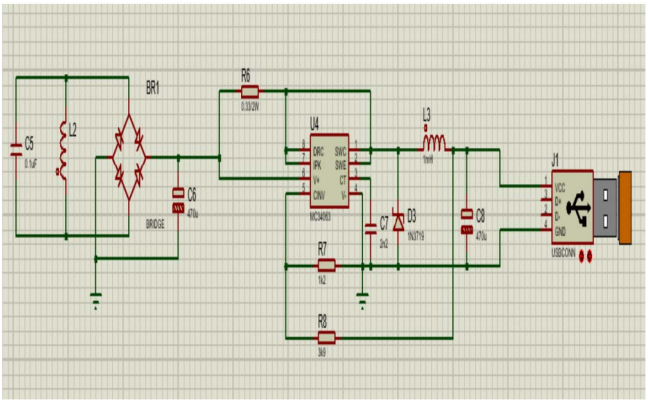

Fig. 10. Circuit diagram for receiver side.

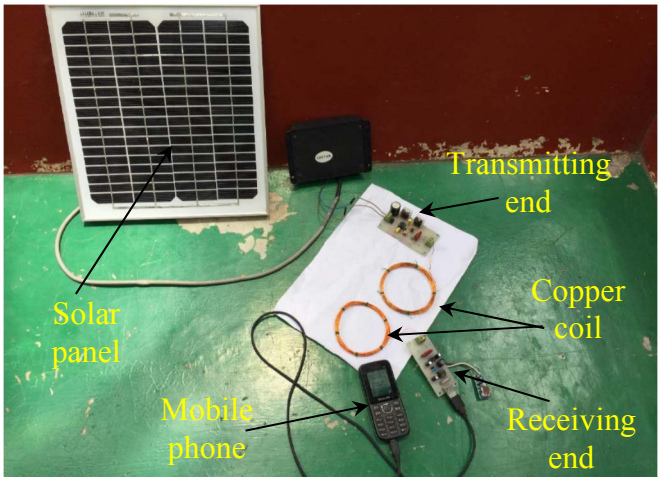

Fig. 11. Final setup for solar power wireless battery charger.

Table I. COMPONENTS OF SOLAR POWER WIRELESS BATTERY CHARGER.

Components	Amount
ICMC34063	1 pcs
Heat sink	2 pcs
3.3 resistor	10 pcs
Copper wire	25 Gauge
Solar panel	1 pcs
1n 4007 diode	4 pcs
IC 555 timer	1 pcs
Capacitor	8 pcs
Inductor	3 pcs
PCB	2 pcs
Schottky diode	1 pcs
BC547 (General purpose NPN transistor)	1 pcs
LM7805 (Series voltage regulator, 5V)	1 pcs
IRF540N (N-channel MOSFET)	1 pcs

V. RESULTS ANALYSIS

This proposed model is related to wireless power transmission. Power transmission happens because of the electromagnetic field. Transmitter side receives the input solar power and converts it into an oscillating magnetic field with the help of copper coil. At the receiver end, this oscillating magnetic field creates an induced voltage and finally, the battery of a device is charged.

The charging operation of a mobile phone is shown in Fig. 12.

Fig. 12. Charging a mobile phone.

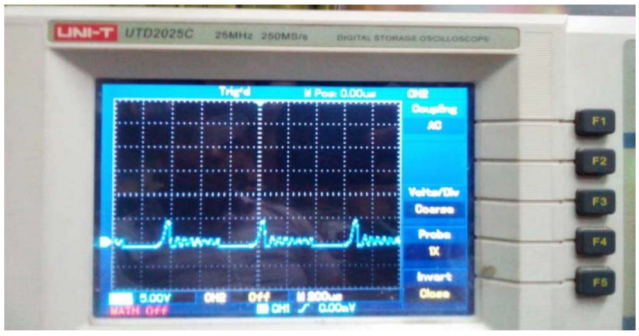

Fig. 13. Wave shape for the input voltage.

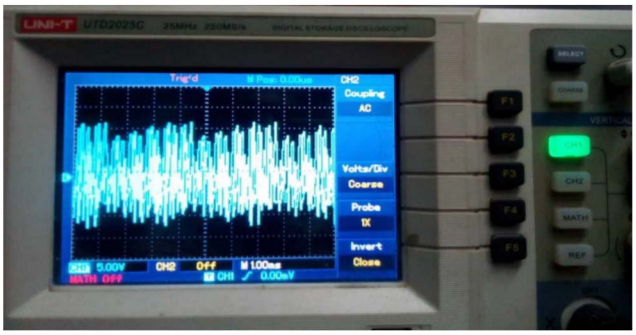

Fig. 14. Wave shape for the output voltage.

VI. CALCULATION

As the IC 555 timer is wired in "astable multivibrator" so, pulse oscillation has to calculate. It is known that there are three modes for IC 555 timer, i.e. bistable, monostable, astable. Astable multivibrator puts out a continuous stream of rectangular pulses.

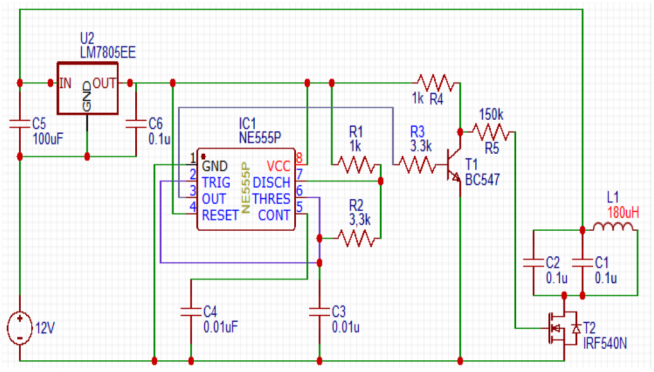

Fig. 15. Transmitter Circuit of the system.

Now, high time or charging time for each pulse

$$= \ln(2) \times C3 \times (R1 + R2) \quad (1)$$

$$= 0.693 \times 0.01 \times 10^{-6} \times (1000+3300)$$

$$= 29.79\mu \text{ sec.}$$

The low time or discharging time from each pulse

$$= \ln(2) \times C3 \times (R1 + R2) \quad (2)$$

$$= 0.693 \times 0.01 \times 10^{-6} \times (3300)$$

$$= 22.87\mu \text{ sec.}$$

The oscillating frequency of 555 timer IC or frequency of pulse stream,

$$f = \frac{1}{\ln(2) \times C3 \times (R1 + R2)} \quad (3)$$

$$= 18.94 \text{ kHz.}$$

L-C tuned frequency for the transmitter,

$$Ft = \frac{1}{2\pi\sqrt{LC}} \quad (4)$$

$$= \frac{1}{2\pi\sqrt{180 \times 10^{-6} \times 0.2 \times 10^{-6}}}$$

$$= 26 \text{ kHz.}$$

L-C tuned frequency for the receiver,

$$Fr = \frac{1}{2\pi\sqrt{LC}} \quad (5)$$

$$= \frac{1}{2\pi\sqrt{180\times10^{-6}\times0.2\times10^{-6}}}$$

= 26 kHz.

Output voltage = 3.8 Volt and Output current = 0.35 A

Output power =Voltage × Current

= 3.8 V × 0.35 A

= 1.3312 watt

Input Voltage = 12 V and Input Current = 1 A

Input power = Input Voltage × Input Current

= 12 V × 1 A

= 12 watt

Now, Efficiency = Output power / Input power

= 1.3312 / 12

= 0.11

= 11%

In this study, the efficieny is low (11%) because power loss occurs due to the power transferring process through some passive devices.

VII. Advantages Over the Traditional Model

The handset is usually charged these days by using electricity, generated and supplied from different power stations. But this proposed system does not need any connection with this type of conventional power sources to charge a handset. The handset will be charged through solar power. So, additional electricity is no longer needed to charge a phone's battery. In addition, this wireless system does not require any wire to connect with the device for charging. Handset just needs to drop onto the charging dock and things start working without having to plug anything into the phone. This is significantly easier than traditional wired charging method. So, plugging and unplugging a cable is no longer necessary in every time to charge a phone.

VIII. Limitations Of the System

As we know, nothing is perfect and long lasting in today's world. Same goes with wireless charging. One of the main reason behind unsuccessful of wireless charging on extended large distance. The charging transmitter still needs to be connected to a power source so we cannot be moved everywhere. Certain wireless chargers cannot reach the same level of efficiency as traditional charging, so the process tends to be slower. As our project is solar based so sometimes it is very difficult to produce sufficient power as needed. In addition, the heat generation of wireless charging technologies is generally higher with the conventional charging method.

IX. Future Enhancement

Basically, the wireless solar charger is designed to charge the mobile battery. But in the future, by making some modifications, it can be used for different portable devices, for example, Laptop, iPad, digital camera, electric vehicles. With the development of the extended distance wireless charging, it is possible to charge the devices by walking outside on the street. It will work like a hotspot area similar to a Wi-Fi hotspot, the device gets charging while users are walking or speaking. Now, wireless charging would allow the vehicles to power up. This wireless charging vehicle would not use plugs or charging cords. Drivers would park their electric vehicles over a wireless energy source. Then the system will automatically transfer power to the battery charger on the vehicle. These electrochemical high rate batteries can be used for wireless charging vehicles. So within very short times vehicles will be charged.

X. Conclusion

Solar power wireless charger can charge the battery very efficiently without any wire. This wireless charging system is ideal to use for many portable devices such as mobile phones and other wireless applications. This study is based on solar power and wireless technology. So during load shedding and traveling, electronic devices can be easily charged without any wire and charger. This system is actually very efficient and environment friendly.

***Abstract*— The objective of this paper is to obtain appropriate offshore location in the Bay of Bengal, Bangladesh for further development of wind energy. Through analyzing the previous published works, no offshore wind energy estimation has been found related to the Bay of Bengal. Therefore, this study can be claimed as the first footstep towards offshore wind energy analysis for this region. Generally, it is difficult to find offshore wind data relative to the wind turbine hub heights, thus a starting point is necessary to identify the possible wind power density of the region. In such scenario, Synthetic Aperture radars (SAR) have proven useful in previous studies. In this study, SAR based dataset- ENVISAT ASAR has been used for Wind Atlas generation of the Bay of Bengal. Furthermore, a comparative study has been performed with Global Wind Atlas (GWA) to determine a potential offshore wind farm production in a reasonable location at the bay. The annual energy production of that offshore windfarm has been analyzed by combining SAR, GWA and ASCAT datasets. Through ASAR based Wind Atlas and GWA comparison, some differences have been found where there are less samples from the ASAR datasets. Thus, Weibull statistical analysis are performed to have a better Weibull fitting and accurate estimation of Annual Energy production (AEP). The study summarizes that, satellite datasets can be a very useful method to detect potential zone if compared with any long time statistical result and bathymetry data together.**

Keywords— Wind Atlas, Satellite wind measurements, Weibull distribution, ASCAT ,ASAR, Offshore

I. INTRODUCTION

Increasing demand of offshore wind parks in various countries has promoted wind resource mapping over the sea. The original method to estimate the wind energy resource is by installing a meteorological mast at one or more specific sites for minimum one year. This mostly requires more time as well as becomes costly and this drawback leads to search of another alternative method which gives indications of wind resources and help in proper decision making of feasibility studies for the prospective wind parks. In such scenario, satellite remote sensing is useful. Execution of these satellite based images in order to derive wind speed in the early stages of wind farm planning is becoming praiseworthy because of its spatial and time coverage along with cost effectiveness [1]. This useful method can predict perfect area of higher wind resources which leads to the planning of feasibility studies and provide a faithful supplement to the traditional assessments [3].

The main study area is chosen as the Bay of Bengal, which is considered as the largest Bay of the world which comprises around 2090 km of length and 1610 km of width. The total surface area of Bay of Bengal is around 2 million km^2 and it is bounded by Sri Lanka and India in the west side, Myanmar and Andaman and Nicobar islands in the east side and Bangladesh in the North side. It has a high depth of around 5 km and average depth of 2600 m which can be an impeccable study area for offshore floating wind turbines [2]. Broad wind analysis has not been performed yet in this bay to find out the wind energy resources, only few studies have been done in the Indian coasts which just covers a specific western zone of the Bay of Bengal. Also, no wind atlas generation for larger domain and wind energy estimation has been performed in the Bay of Bengal which is the main concentration of this paper.

In our study, the obtained datasets were compared with the Global Wind Atlas (GWA) datasets. GWA provides long-term high resolution wind climatology at 50, 100, 200m hub heights for the whole world including onshore and 30 km from offshore as a free access online [12]. This wind atlas provides wind resource data at 1 km resolution and contains data at a higher spatial resolution of 250 m [12]. The information provided in the Atlas along with further specific regional studies, supports to identify the prospective areas for additional preliminary assessment of technical possibilities.

II. SATELLITE TECHNOLOGIES FOR OFFSHORE WIND

In this paper, two types of satellites were analyzed which are: Synthetic Aperture Radar (SAR) and Scatterometer. The studied datasets were attained from SAR methodology based Advanced Synthetic Aperture Radar (ENVISAT ASAR) and from Advanced Scatterometer (ASCAT) satellites.

A. Synthetic Aperture Radar (SAR) technology

SAR is a remote sensing technique which transmits microwave pulses of energy to illuminate an area of the Earth surface. The pulses gets scattered because of the surface properties and a portion returns to the instrument with a change in amplitude, polarization, travel time and phase [3]. All these backscattered signals for each foot print area stores in the satellite to process a two dimensional image of the surface. SAR has higher spatial resolution (around 1km) and preferred more for coastal wind energy measurements [5].The data acquisition from the SAR pulses can be performed in day or night even if it is cloudy or light rainy (Christiansen, 2006). SAR signals are electromagnetic waves with a polarization determined by the orientation of the electric field [3]. Some upgraded SAR systems have the capability of transmitting and receiving both polarization simultaneously, and deliver quad observable SAR images [4].

ENVISAT ASAR (Environmental satellite based Advanced Synthetic Aperture Radar) satellite is based on SAR technology and it is actually an Environmental satellite capable of scanning the surface in one of the four polarization combinations. [4]. The mission was later followed up by the

Sentinel-1 A/B mission. It is being established by European Space Agency (ESA) in 1 March,2002 until 9 May, 2012, when ESA lost the contact with the satellite [5]. The satellite take images and send to the base station down in earth to preserve. The spatial resolution of the images is around 150 m and swath mode around 400 km. The total incidence angle coverage is 15-45 degree [3] . In the scenario of ocean winds, the average of around 1km resolution is processed for SAR images in a purpose to lessen the natural speckle noise and modulation error [9]. In WSM (wide swath mode) of SAR data acquisition, it can map a point at mid-latitude (55°N) around 15 times per month [9]. The ENVISAT ASAR dataset is freely accessible from the European Space Agency (ESA) archive from where the required data can be downloaded and used for further scientific research studies.

B. Scattterometer Technology

Scatterometer is a real aperture radar that also uses microwave technology are sun – synchronous polar orbiting satellites similar to SAR. These kind of satellites have a fixed local time of observations for ascending and descending mode. Scatterometers operate in the radar scale of C-band (around 5 GHz) or in Ku-band (around 13 GHz)[5]. One of the prime differences in between Scatterometer and SAR is that, Scatterometters take multiple (3 to 4) views of the surface from the antennae while SAR takes only one directional view. Due to this higher area coverage capability Scatterometer's observation rate is higher than SAR [5].

In October 2006 the Advanced Scatterometer (ASCAT) was launched on the EUMETSAT (European Organization for the Exploitation of Meteorological Satellites) MetOp-A which is Meteorological Operational satellite program (MetOp) and became completely operational from May, 2007 until today[6]. From September 2012, MetOp-B became operative, whereas both of these satellites has same ASCAT instruments.[.Being a C-Band scatterometer, ASCAT operates two times a day (day and night) through its 3 vertically polarized antennas transmitting pulses at 5.255 GHz [7]. ASCAT has a double swath as the fan-beam antennae is slanted towards 45, 90, and 135° with satellite track where the extended side of antennae possesses two swaths each consisting of 550 Km wide separated by a gap of about 670 Km nadir gap. [14] Having two swaths ASCAT can provide mapping of all locations at a midpoint (55°N) around 40 times per month [9]. Comparing with ENVISAT ASAR it has more frequent imaging as ASAR maps 15 times per month for the same midpoint.

III. DATA ANALYSIS OF THE BAY OF BENGAL

The fundamental of this paper is to create a wind atlas for the Bay of Bengal by using ENVISAT ASAR datasets and through a comparative analysis with Global Wind Atlas (GWA), finding a suitable location for wind farm estimation. In this paper, the wind atlas methodology has been followed to create a wind atlas. This step by step process has been displayed in a flow chart below. The interest area of our study locates in UTM 45N zone, at 82° to 95° Eastern longitude and 16.5° to 23° Northern latitude.

A. ASAR datasets

The Bay of Bengal has been mapped through ASAR on-board by European Space Agency satellite ENVISAT from 2006 until 2012. A total number of 466 Wide Swath Mode (WSM) scenes from 2002 until 2012 are collected from the ESA's ordering system EOLI-SA (Earth Observation Link) with special request by DTU. Each of those WSM scenes cover 400 x 400 km.

After receiving the WSM scenes, the wind retrieval offshore wind maps were produced. This whole process of the wind retrieval is done with a patented software called by ANSWRS (Applied Physics Laboratory National Oceanic and Atmospheric Administration (NOAA) SAR Wind Retrieval System)[3]. ANSWRS is a well effective software for wind retrieval from the ASAR WSM scenes which has been used in all previous SAR based offshore wind atlas generation [3] [8][9] [10] [11]. The SAR wind directional data was attained at 1 degree latitude and longitude resolution from the US Navy Operational Global Atmospheric Prediction System (NOGAPS)[5]. NOGAPS is modeled as 6-hourly wind direction provider which were interpolated spatially to be suitable for usage with the SAR images as previously it has been mentioned that, SAR only takes one directional images. So it cannot detect the wind direction by itself. For geophysical model function CMOD-5.n is being used. CMOD-5.n is an updated version of the CMOD5 which provides neutral condition of wind speed at 10m [5]. In the below Figure 2, it represents two ENVISAT ASAR WSM wind scenes on the date of 26 June, 2010 and 9 March 2009 respectively in ascending and descending formats.

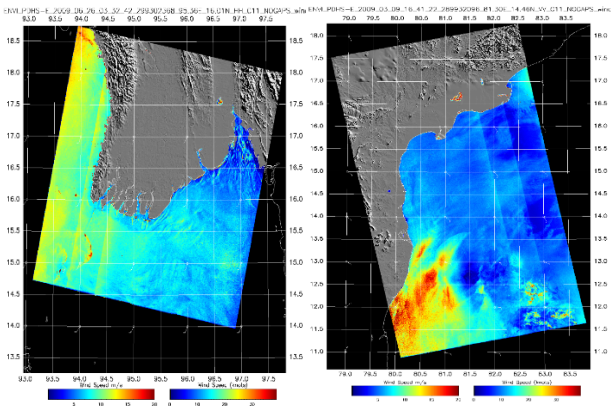

Figure 1: ENVISAT ASAR retrieved wind scenes of 26 June 2010 and 9 March 2009 at 16.41:22 and at 03.32:42 UTC in the Bay of Bengal accordingly.

The satellite wind retrieved fields received from the DTU were merged and combined for wind resource mapping using the DTU Wind tool S-WAsP. In S-WAsP, a second moment fitting for the Weibull scale (A) and shape (k) parameters are used to fit a distribution to all data and estimate the two Weibull parameters.

B. ASCAT datasets

In this study, the similar way, ASCAT datasets has been received and further retrieved to achieve wind scenes for that specific location. National Oceanic and Atmospheric Administration (NOAA)'s weather forecasting and warning mission operationally supports the production and utilization of ASCAT ocean surface vector wind products[15]. Royal

Netherlands Meteorological Institute (KINMI) has developed the ASCAT wind data processor for the standard ASCAT wind by using GMF CMOD5.N [15]. KNMI produces the gridded version (cell size of 12.5 km) product of ASCAT wind speed and direction within EUMETSAT OSI SAF. (SAF, 2013). In our study, ASCAT observations are extracted from the ASCAT Level 3 Coastal Ocean Surface Wind Vector product (MyOcean). L3 daily gridded wind product is available from the MyOcean catalogue after registration at their site for the defined location.

C. GWA datasets

For this paper, the global wind dataset were collected in modern Era-Retrospective Analysis for Research and Applications (MERRA) format from the free access internet as .lib files for definite co-ordinates and then matched those nodal points with the obtained SAR data locations. In the concerned area, the sample nodal locations of SAR .lib files were matched with the downloaded GWA location defined .lib files for 10m height.

IV. STATISTICAL ANALYSIS

For analyzing the wind speed data, the two parameter Weibull Probability distribution function (PDF) is most appropriate and acknowledged. This PDF provides an enhanced fitting to predict high accurate monthly distribution of wind speed. The Weibull Probability function is denoted in [16] as:

$$f(v) = (\frac{k}{A})(\frac{v_i}{A})^{k-1}\exp[-(\frac{v_i}{A})]^k \quad (1)$$

where $f(v)$ is denoted as the probability of observed wind speed, A is the Weibull scale parameter and k is the unit less Weibull shape parameter, v_i is wind speed. The two Weibull parameters and the average wind speed are related by [16]

$$\bar{v} = A.\Gamma\,(1+\frac{1}{k}) \quad (2)$$

By using the Weibull parameters, gamma function Γ and the air density ρ (~1.245 g m−3) the wind power density is predicted in [16] as:

$$E = \frac{1}{2}\rho A_w^3.\Gamma\left(1+\frac{3}{k_w}\right) \quad (3)$$

where $\bar{v}$ is the average wind speed, E is the power density and Γ is the gamma function. In this study, four methods of statistical analysis were compared to determine the shape and scale parameters of Weibull wind speed distribution for wind energy resource analysis, these are:

A. Empirical Method

Empirical method (EM) is a comparison set using the standard deviation and mean wind speed. It is considered as a distinctive situation of Method of moments (MOM). Through EM the parameters of Weibull distribution can be found from [16] as:

$$k = (\frac{\sigma}{\bar{v}})^{-1.086} \quad (4)$$

$$A = \frac{\bar{v}}{\Gamma\,(1+\frac{1}{k})} \quad (5)$$

where $\bar{v}$ is the average wind speed, σ is the standard deviation and Γ is the gamma function.

B. Method of Moments

In estimating Weibull distribution parameters Method of moments (MOM) is widely used. The equation format is dependent on the arithmetical iteration of mean wind speed ($\bar{v}$) and standard deviations (σ). The equations [16] are followed as:

$$k = (\frac{0.9874}{\frac{\sigma}{\bar{v}}})^{1.0983} \quad (6)$$

$$A = \frac{\bar{v}}{\Gamma\,(1+\frac{1}{k})} \quad (7)$$

where $\bar{v}$ is the average wind speed, σ is the standard deviation and Γ is the gamma function.

C. Method of Moment 3

By Moment 3 method of Weibull parameter estimation, first the k parameter is being determined from [17] through equation 4.12.

$$\frac{\bar{v}^3}{(\bar{v})^3} = \frac{\Gamma(1+\frac{3}{k})}{\Gamma(1+\frac{1}{k})^3} \quad (8)$$

Afterwards the A parameter is determined from

$$A = \frac{\bar{v}}{\Gamma\,(1+\frac{1}{k})} \quad (9)$$

where $\bar{v}$ is the mean wind speed and Γ is the gamma function

D. Power Density Method

The power density method (PDM) is a numerical analysis related to the mean wind speed and for this method initially the Energy Pattern Factor (E_{pf}) should be computed. E_{pf} can be defined as the ratio of mean of cubic wind speed to the cube of mean wind speed. The energy pattern factor (EPF) denoted in [16] as:

$$E_{pf} = \frac{\frac{1}{N}\sum_{i=1}^{N} {v_i}^3}{(\frac{1}{N}\sum_{i=1}^{N} v_i)^3} \quad (10)$$

Subsequently, the shape parameter (k) and scale parameter (A) can be calculated from the previous E_{pf} equation through below format described in [16] as:

$$k = 1 + \frac{3.69}{{E_{pf}}^2} \quad (11)$$

$$A = \frac{\bar{v}}{\Gamma\,(1+\frac{1}{k})} \quad (12)$$

where $\bar{v}$ is the average wind speed, v_i is the observed hourly wind speed, E_{pf} is the energy pattern factor. With the aim of evaluating the accuracy of the previously mentioned 4 Weibull methods, 3 types of error estimation has been calculated. Those are:

E. Root Mean Square Error (RMSE)

RMSE estimates the error by considering the deviation between the predicted and the experimental values. The lower the value of RMSE is, the more accurate the values are. RMSE should be as close by to zero as possible to have a successful forecasting of prediction. The equation formula of RMSE is described in [16] as:

$$\text{RMSE} = (\frac{1}{N}\sum_{i=1}^{N}(y_i - x_i)^2)^{1/2} \quad (13)$$

where, y_i is the frequency of the observation , x_i frequency of Weibull (using those statistical methods) and N is the number of observations.

F. Chi-Square Test(χ^2)

This test is considered accurate when the value comes closer to zero. Basically it gives back the mean square of the deviations between the experimental and the calculated values for the distributions. Chi-squared test is calculated in [16] as following:

$$\chi^2 = \sum_{i=1}^{N} \frac{(y_i - x_i)^2}{x_i} \quad (14)$$

where, y_i is the frequency of the observation x_i frequency of Weibull (using those statistical methods) and N is the number of observations.

G. *Coefficient of Determination (R^2)*

The coefficient of determination (R^2) represents a linear relationship between the calculated values and observed data. The higher value of it represents a better fit and the highest value it can get is 1. The function can be represented in [17] as:

$$R^2 = 1 - \frac{SS_{RES}}{SS_{TOT}} \quad (15)$$

$$where,\ SS_{RES} = \sum_{i=1}^{N}(y_i - f_i)^2 \quad (16)$$

$$SS_{TOT} = \sum_{i=1}^{N}(y_i - \bar{y})^2 \quad (17)$$

Here, y_i is the frequency of the observation, $\bar{y}$ is the mean of the observed data, N is the number of observation, f_i is the predicted value.

V. RESULTS

The purpose of this section is to combine all the satellite datasets to generate a Wind Atlas of the Bay of Bengal and have a comparative study among GWA and satellite datasets.

H. *Wind Atlas Generation*

After S-WAsP mapping of the achieved wind scenes, the time-series wind measurement dataset is being generated as .tab files which is a file format for observed wind climate. From then the forming of a generalized wind climate in .lib file begins which is format of the Atlas files. For this instance, a vector map of the whole zonal area is used for specific terrain analysis and a met-station for the site precise location is settled up in WAsP.

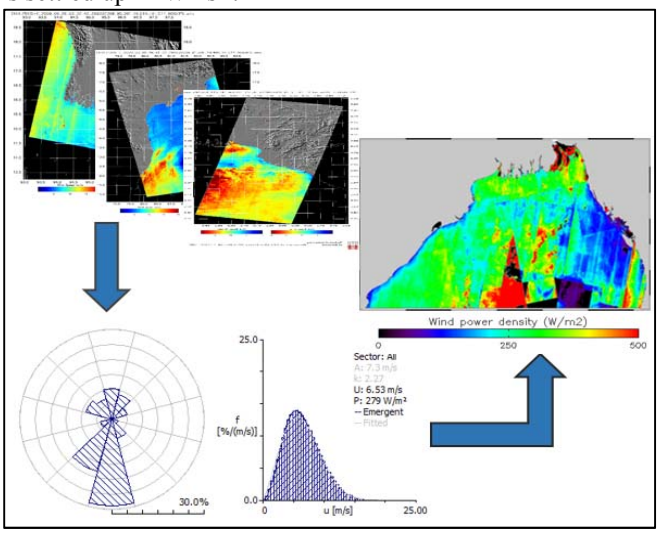

Figure 2: Wind resource mapping process from ASAR wind scenes

If the met station location is preferable and specific under that zonal area, the Generalized Wind Climate can be further calculated. For each .tab file, the same procedure is followed to create the respective .lib files. The generated .lib file contains the sectoral wise frequency of occurrence of the wind (the wind rose) as well as the wind speed frequency distributions in the same sectors (as Weibull A- and k-parameters). The wind climates are specified for a number of reference roughness classes and heights above ground level.

For specific roughness and height selection, it provides a combined 12 sectoral wind rose, sectoral frequencies of the wind direction, mean wind speed, mean power density along with Weibull shape (k) and scale (A) parameters

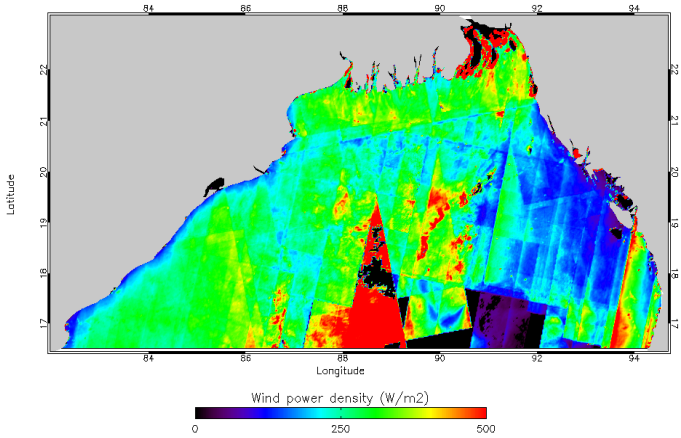

Figure 3: Wind Power density map of the Bay of Bengal through ENVISAT ASAR wind dataset

B. *Comparison and Outcomes*

The nodal comparison was done in an area basis (60 km by 60 km) keeping the GWA node points in the middle. So these area wise nodal comparisons were performed where 122 coordinated nodal location points are found in the defined zone. While comparing the Satellite based Atlas with GWA, we have found in further from shore areas, the number of samples are really scanty which leads to a lower data obtain scenario of that particular area. The higher the number of samples, the better the estimation can be provided. In addition, from previous studies it has been perceived that, wind resources can be predicted well enough through 70 samples considering an uncertainty of ±10% at a confidence level of 90% [13]. To gain more accuracy, those ENVISAT ASAR nodal locations were chosen which has more than 70 time series samples. This lead to 26 nodal sample comparison in between GWA and ENVISAT ASAR wind atlas.

In the figure 4, 5, 6 and 7, the scenes which has more than 70 time series samples has been selected. For this reason other nodal points of deep sea is showing as null values. From the figure, two particular interest areas can be found where the number of samples are moderate, which is in the Northern coastal area near Bangladesh and in the Western side of the Bay of Bengal near India. While comparing the mean wind speed verified ENVISAT ASAR wind Atlas map with GWA, ENVISAT ASAR wind Atlas map shows a moderate result, though the ASAR seems to be over predicting the wind speed and energy entirely, especially in the Northern coastal areas.

In the figure 4, it shows the calculated offshore mean wind speed from ENVISAT ASAR datasets. The color legend shows the variation of mean wind speed availability of that particular zone of the Bay of Bengal. From the legend it is clear that, the color orange to red is the high potential zone whereas the color below are indicating a lower wind speed scenario. Figure 4 represents a variation of around 6-7.5 ms^{-1} mean speed. In the Northern side of the Bay of Bengal, the mean wind speed is around 6.5-7.5 ms^{-1} where as in Eastern part it varies around 6-7.29 ms^{-1} On the other hand, figure 5 represents the GWA mean wind speed for the same location points where GWA shows a variation of wind speed from

5.05 to 7.82 ms- Alike SAR, It can be seen that in Western side of the Bay of Bengal, the mean wind speed is found to be around 6.5-7.2 ms^{-1}.

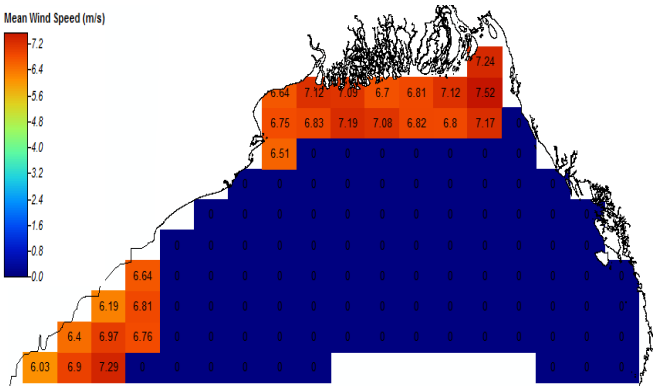

Figure 4 : Mean wind speed of the specified location from ENVISAT ASAR datasets

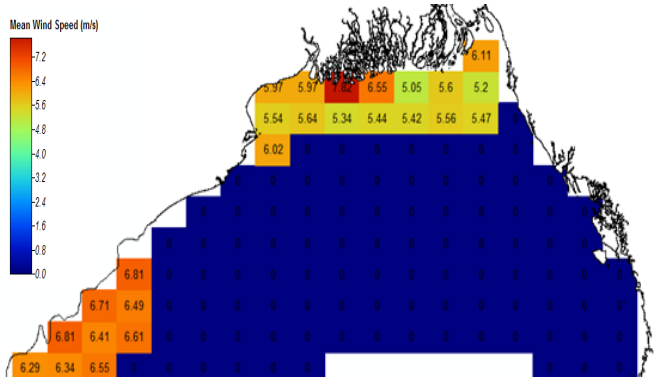

Figure 5 : Mean wind speed of the specified location from GWA datasets

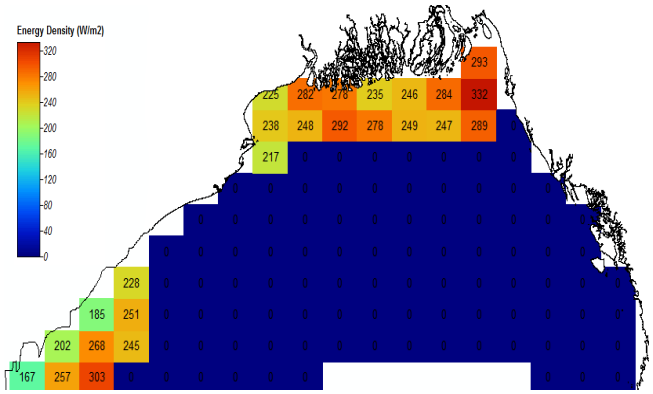

Figure 6. Energy density of the specified location from ENVISAT ASAR datasets.

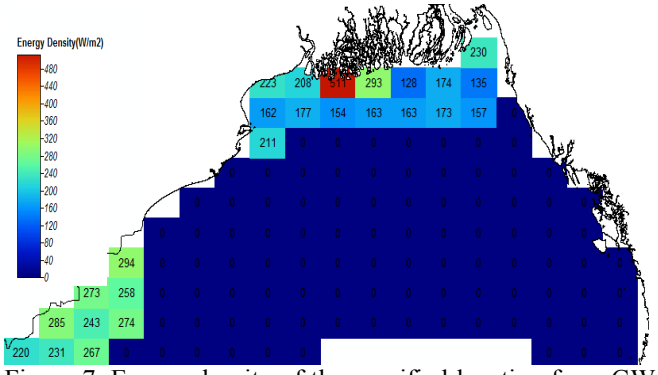

Figure 7. Energy density of the specified location from GWA datasets

Figure 6 represents the energy density from ENVISAT ASAR datasets for the specific location where it shows a good variation of 225-332 W/m2 in near coastal area of Northern side of the Bay of Bengal where as in Western coast it is a bit less comparatively (167-303 W/m2). On the other hand, from the wind energy density verified GWA map, the energy density is found to be 162-293 W/m^2 in the Northern nearshore area (Figure 7). Where as in a specified location, it is estimated to have around 511 W/m^2 of energy density. Another corner of the map which is situated in the Western coast, the variation of 231-294 W/m^2 energy density has been found.

VI. Test Case

A case study has been performed through assembling all the obtained datasets (ASAR, GWA and ASCAT). Through an engineering application this test case has been approached to estimate an offshore wind park production for an appropriate zone at the Bay of Bengal.

A. Selection of the suitable location

The main focus is to create a 400 MW wind farm at low depth sea locations but high in power density; which is 4-6 km close to the shore, so that it does not require any supplementary base station and additionally, it will reduce the cost of the offshore wind farm installation. The proceeding steps of this engineering application has been displayed in a flowchart below.

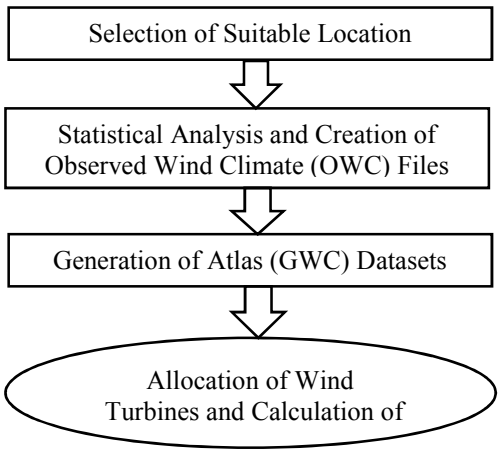

Figure 8. Flowchart of Case Study Phases

Our achieved SAR and GWA power density maps were analyzed to find a comparable higher energy density area comprising higher sample number of SAR dataset. When a point location has more number of SAR samples that represents more data acquisition in the time domain which can lead to a reliable estimation of wind energy density. Also, another preferences were to find a nearshore, lowest depth and highest potential area for case study purpose. To apply the newest technology of offshore wind turbine in the specified area, it leads to operational uncertainty and more expenses. That is why the conventional turbine installation techniques has been preferred in this section.

Therefore, based on four detailed criterion, the zone has been selected as (1) Sufficient number of satellite data sample to get more accurate results. (2) Highest wind energy density region as an aspect to highest energy production. (3) Nearest to shore to not to have a base station in offshore. (4) Lowest

depth region to deal with the present technology of the offshore with turbine.

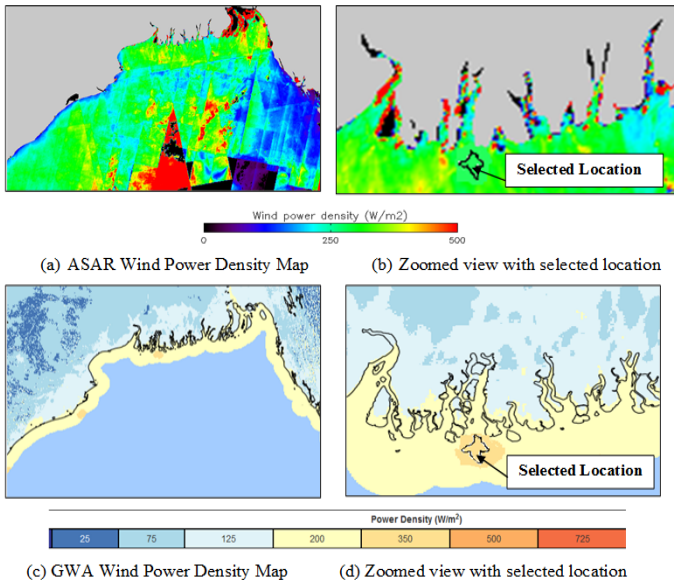

Fig 9. Selection of the suitable location

To determine a potential region for wind farm setting, selection of the highest wind energy density location is a must. For this purpose, the attained ASAR based Atlas and GWA power density maps were well analyzed to find out a specific zone with equivalent high power density (fig 9). In order to perform detailed analysis, the sample number of ASAR datasets were prioritiezed as a purpose of achieving more accuracy in wind energy estimation.

For a purpose of depth analysis of the Bay of Bengal, the bathymetry map has been downloaded in Shuttle Radar Topography Mission (SRTM) 30+ version of 30 arc second, Global. SRTM 3-arc second resolution digital elevation maps (DEM) have been merged with the vector map of the Bay of Bengal and divided in 6 zonal divisions. The target was to focus on the lowest depth zone and near to shore location.

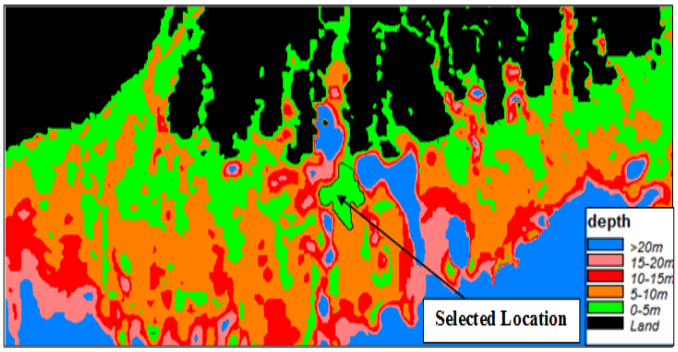

Figure 10. Bathymetrical segmentation of the Bay of Bengal

After investigating the figures of 10 and 11, such close to shore, higher sample number and lower depth areas with higher wind power density was found to be existed only at the northwest coast of Bangladesh. Therefore, the area has been chosen at the location of 21.5° Northern latitude and 88.667° Eastern longitude. This area is in the depth region of 0-5m, 5 km away from the coastline, comprising one of the highest sample numbers of 122 of ASAR datasets and predicted to have higher wind power density in an assumption from GWA and ASAR based wind datasets. In addition, ASCAT dataset was obtained for the chosen area which comprises a full year of 2015 measurements. The dataset contains 567 time series samples that fairly distributed in every single month and ascending-descending arrangement. This obtained ASCAT dataset is more frequent than ASAR datasets due to its technological aspects. Both of the satellite datasets were analyzed accordingly to get a broader interpretation.

B. Implying the statistical analysis

In our study, we investigated Weibull fitting by 4 methods as Empirical method (EM), Moment Method (MOM), Moment 3 method (MOM 3) and power density method (PDM) in the selected zonal area for wind farm. In addition, the relative accuracy test of Root Mean Square Error (RMSE), Chi-Square (χ^2) and Coefficient of determination (R^2) has also performed to predict the energy density uncertainty. Here, it should be mentioned that, RMSE and (χ^2) is considered more accurate when it is near to zero and (R^2) is considered more accurate when it is near to its highest value of 1.

TABLE 1. TWELVE SECTORAL STATISTICAL WEIBULL ANALYSIS OF ASAR DATASETS

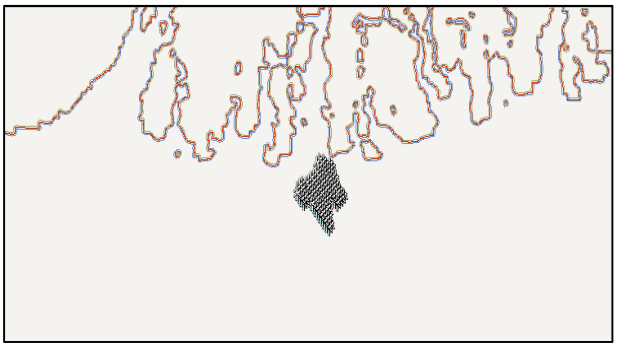
Method	A	k	v_m	RMSE	χ^2	R^2
EM	7.39	2.09	6.54	0.00654101	0.104194	0.88102
MOM	7.39	2.07		0.00653913	0.103496	0.881089
MOM3	7.392	2.12		0.00655685	0.106151	0.880443
Epf	7.392	2.13		0.00656684	0.1071	0.880079

TABLE 2.TWELVE SECTORAL STATISTICAL WEIBULL ANALYSIS OF ASCAT DATASET

METHOD	A	K	v_m	RMSE	χ^2	R^2
EM	6.24514	2.21076	5.53095	0.003134	0.059732	0.914321
MOM	6.2453	2.19501		0.003104	0.058549	0.915931
MOM3	6.24533	2.18982		0.003095	0.058197	0.916435
EPF	6.24526	2.19938		0.003112	0.05886	0.915497

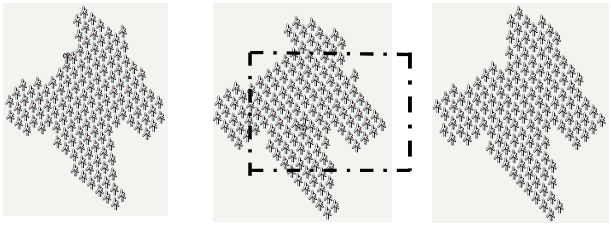
From the results, the MOM 3 method was chosen to be the best fit for the datasets and further WAsP analysis has been performed to predict the annual energy production of that particular area.

C.Reformation of Sectoral division



As the observed dataset of our study did not have efficient sample numbers for each sector, the samples were too few to count, that is why another proposed idea has been represented here. The proposed idea is to obtain more wind speed datasets in one sector, by reforming the sectoral division to 60 degree from 30 degree. So, in spite of having 12 sectors now, 6 sectoral representation has been investigated. As a result, the number of

samples for wind speed calculation increased in every sector and it shows a better result of Weibull fitting.



D.Wind Farm Layout

The selective zone was calculated and found to have 174.5 km^2. Based on this area, a minimum production from that extent was designed via allocating 134 turbines. These 134 turbines were chosen to have 3MW capacity individually. This results as estimation of 402 MW capacity offshore farm with 2.3 MW/ km^2 energy distribution per area. In our study, Vestas V112-3.0 MW model of turbine has been chosen which has a rotor diameter of 112 m and hub height of 84m. As at present, mostly used turbines are of around 3 MW for offshore wind technology, our turbine specification has been chosen accordingly. Turbines were set in an equidistant of 10 diameter from each other as a way to let the wind recover from turbine to turbine.

Turbines front sides were also considered depending on the dominant wind directions. It was found to be 229.459°, 218.015 for ASCAT and ASAR datasets respectively. The dominant direction for every sector has been determined by combining the wind speed and frequency generation of that respective sector and the opposite sector. In the below figure 11 the different wind farm layout based on the leading wind direction is presented where it shows a slight rotation of wind turbines formats.

(a) Selected area of turbine allocation

SAR (218.015 °) ASCAT (229.459°) GWA (232.2 °)

Figure 11. Wind farm layout for every datasets.

E.Calculation of Annual Wind Energy Production

After the wind farm insertion to the selective WAsP file, the calculation of Annual Wind Energy has been performed. The gross AEP is the energy production of a single turbine through corresponding wind distribution at the predicted hub height in the form of the supplied power curves. In gross AEP, the wake effect is not accounted. And for Net AEP case, the wake effect is counted as it the whole total annual energy of the farm. By the intricacy of this power curve and numerical wind distribution, each turbines annual energy production is calculated. Afterwards, by combing the each turbines annular energy and wake loses, the AEP is calculated for the whole wind farm.

TABLE 3. CALCULATION OF AEP USING MOMENT 3 METHOD

Source	Gross AEP (GWh)	Net AEP (GWh)	Wake Loss (%)
ASAR 12	1792	1693	5.52
ASAR 6	1793	1682	6.22
ASCAT 12	1385	1310	5.45
ASCAT 6	1379	1269	7.99
GWA	1352	1276	5.61

The above table (table 3) shows AEP estimation through MOM 3 method for all three datasets in 5 forms which are- ENVISAT ASAR for 12 sector and 6 sector, ASCAT for 12 sector and 6 sector and GWA. The results are quite similar among ASCAT and GWA, whereas ENVISAT ASAR datasets has an overestimation.

TABLE 4. ERROR CALCULATION OF SATELLITE DATASETS WITH RESPECT TO GWA.

Source	**Sector**	**Error Rate (%)**
ENVISAT ASAR	12	28
ENVISAT ASAR	6	27.6
ASCAT	12	2.6
ASCAT	6	0.5

While comparing the 12 sectors, it estimates a higher NET AEP, which leads to a higher error rate compared with GWA (table 4). On the other hand, when the sectors are enlarged (from 12 sector to 6 sectors), the error rate is less specially in ASCAT scenario. But the wake losses are found to be in rise when it is 6 sector

VIII. CONCLUSION

For a large offshore area, it is very difficult to define where should be focused on for planning of an offshore windfarm. Even we know, satellite measurements are new and has limited number of samples in any location, they are still the only representative of onsite measurements more than any of the models. Several models of satellites along with its higher number of samples can be used without any local measurements, although this can lead to very big uncertainties. But it can estimate a general region for further broad investigation.

Consequently, in this paper three (ENVISAT ASAR, ASCAT and GWA) remote sensing measurements have been discussed and those datasets were used primarily to generate a wind Atlas of the Bay of Bengal and by utilizing that Atlas a potential zone has been found at a near shore area of the Bay of Bengal. Formerly, a case study has been performed to predict the Annual Energy Production of that particular area. Among these datasets, two (ENVISAT ASAR and ASCAT)

are from satellite based and one (GWA) from long term mesoscale model measurement. The satellite datasets were compared with GWA, as no offshore wind farm has been established in the Bay of Bengal yet and there is no onsite data to have a suitable comparative study.

In this paper, the data analysis on the satellite datasets has been performed along with different statistical methodology selected empirical state of the art moment fitting function to have a better estimation. The initial results with the current dataset shows similar shape and scale parameters for climate values. Therefore it can be understood that, with the limited number of sample datasets, even the simple empirical method are accepted to use. Furthermore, in this study, a potential location has been chosen to define if these data can be used for modeling. As a result all the datasets have given similar production values without directional information. When the directional information is added, less number of data samples were seen to create less quality as it is expected.

The resulted calculation with their error is pointing towards the fact of directional view of wind (sectors) and lesser number of samples. Differences were accounted because of limited data in some sectors. So, reducing number of the sectors were suggested which showed improvement in Weibull fitting, though it has a slight increase in wake effects. Analysis shows that while there is not enough samples, all the methods shows similar results. One can understand from this result that, satellite data can be used to identify the highest density areas for a particular zone but it cannot be used exactly to estimate the highest region. As in our study, the satellite datasets were pointing the same location with GWA and one can make a preliminary analysis of the wind conditions by knowing that it can go up to 20% uncertainty.

From this paper, it can be said that, satellite gives us the ability to identify the higher power density area so that we can utilize it for met mast set up. Even to find a potential zone for establishing mat mast is challenging and time worthy. The foundation of this thesis project is that, satellite datasets can be used to identify potential zone and it has a promising outcome of calculation capability of annual energy production, if compared with any long time statistical result and bathymetry data combination. Furthermore, all three datasets used in this study comprises similar AEP (ASCAT better than ASAR) at the coastal area which indicates the selective location as a potential area and further researches regarding this study can lead towards a better future for the wind energy sector of Bangladesh.

***Abstract*—In this paper, Power generation from the foot overbridge using piezoelectric tile, which is constructed with the piezoelectric transducer, is being discussed. Often more, it is seen, people walk on foot overbridge. Installing piezoelectric tile (Piezotile), we can achieve the huge amount of power, a single piezotile, which has the capability to produce up to 7-watt power, eventually installing numerous piezotile, will provide us with much power, and so power generation from this way is an easy way out. To analyze the mechanical system of the piezotile convert to the electrical circuit and PID controller is used to making the system more stable and increase the accuracy in the piezoelectric transducer. It has the possibility to generate a huge amount of power and this power source has various applications in the home, street lighting, buildings, store energy, emergency power grid and so on. Energy is converted from one form of energy into another and most of the energy is lost in nature. The concept of green energy is to transform various energy into electrical energy. Piezotile is one of them, which convert foot stress into electric energy.**

Keywords*—Foot Overbridge; Footstep; Piezoelectric tile; Piezoelectric; PID; Power Generations; Renewable Energy.

I. Introduction

Usage of the unusable energy of foot stress with human motivity is immensely relevant and significant for dense countries. When the footbridge plane is mechanized with piezoelectric technology, the electrical energy produced by the foot stress is captured by piezotile and then reserved and used as an energy source. The piezoelectric effect has the sufficiency to generate electrical energy in repercussion for the applied foot stress [1]. Piezoelectric transducer has two properties that are defined as a direct and contrary effect. The direct effect is the property of some materials to promote electric charge on their plane when mechanized strength is put on them, while a contrary effect is the property of some materials to produce mechanized strength when an electric charge is induced. Nowadays, the fabrication of piezoelectric nanogenerators (NGs) was demonstrated using piezo materials such as ZnO, $BaTiO_3$, $ZnSnO_3$, $NaNbO_3$, (K, Na)NbO_3, PMN-PT, Ba(Zr, Ti)O_3–(Ba, Ca)TiO_3 and Pb(Zr, Ti)O_3 and so on. Normally, when mechanical stress is not initiated, piezoelectric crystals are neutral meaning their electrical charges are perfectly balanced. If a piezoelectric crystal is aggregated, the natural balance of positive and negative atoms is upset, causing net electrical charges to appear on the opposite, outer faces of the piezoelectric material [2]. The output voltage of a piezoelectric element is given by V = Q/C, where C is the capacitance, Q = d_{33}F is the charge induced by a force, F applied in an approach upright to the piezo electrode surfaces and d_{33} is the relevant piezoelectric coefficient [3]. Pavegen Systems, a technology company based out of London, recently introduced a piezoelectric based tile that harvests the kinetic energy created by a footstep. Their 17.1 by 23.6-inch tiles can produce an average of 7 watts per step. In the Pavegen Systems study, the piezoelectric tiles produce an average of 7 watts per footfall from a 150 pound, walking person [1] [4]. In Fig. 1 Piezoelectric transducer based single and assembled numerous piezotile are illustrated. Piezoelectric transducer based tiles is another prospect of renewable energy.

II. Proposed Structure of Piezoelectric Tile

The proposed design structure of piezotile is shown in Fig. 1. This theoretical piezotile is assembled with the numerous piezoelectric transducer. This total system is fabricated on the foot overbridge. When the tiles mechanized by the foot stress the tiles transfer their energy. Thus electrical power is produced and collected from the piezotile.

(a) (b)

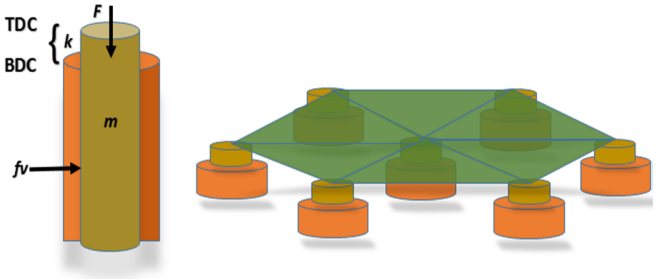

Fig. 1. The design structure of (a) single piezoelectric transducer; (b) and assembled numerous Piezotiles.

The mechanical model of piezotile, the foot stress (*F*), piezoelectric transducer mass (*M*), viscous damper (*fv*), and spring constant (*k*) interchange into the series connected dc voltage source (*v*), inductor (*l*), resistor (*r*) and capacitor (*c*) of the electrical equivalent circuit respectively.

(a) (b)

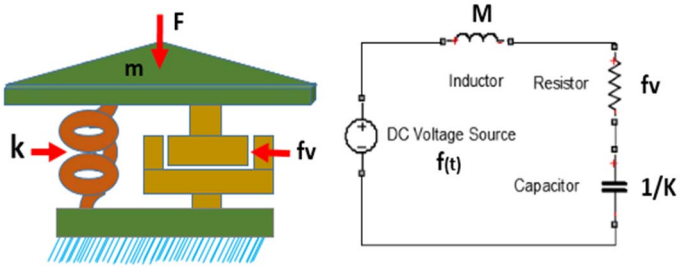

Fig. 2. The mechanical & Electrical model of the Piezotile.

Fig. 2 shows the mechanical model of piezotile transform into the electrical circuit and this is the best technique to analyze the piezotile. The transfer function (*tf*) of the electrical equivalent circuit can be written as:

$$tf = \frac{V(S)}{F(S)} = \frac{S}{MS^2 + f_v S + K} \quad (1)$$

A. Mathematical Representation of Piezotile

In arithmetically for input voltage $f(t)$ and current $i(t)$, the transient power of a piezoelectric transducer can be expressed as,

$$P_{transducer}(t) = f(t) * i(t) = \frac{1}{2} VI[\cos\phi + \cos(2\omega t - \phi)] \quad (2)$$

The effective power, which is the root mean square of the instantaneous power is as following [5],

$$P_{eff} = \frac{V^2}{2|Z|}\sqrt{\cos^2\phi + \frac{1}{2}} \quad (3)$$

Here $V = F_{step}/n$, where F_{step} is the amplitude of the foot stress force on the tile and n is the total number of footsteps on the tile respectively. Moreover, Z is the impedance. The effective input power can therefore be written as [5]:

$$P_{footstep} = \frac{F_{Step}^2}{2n^2|Z|}\sqrt{\cos^2\phi + \frac{1}{2}} \quad (4)$$

The piezoelectric transducer vibrates at the maximum amplitude at the resonance condition, when the inductive reactance, X_L equal to the capacitive reactance, X_C. Then the circuit impedance will be the smallest value and the circuit current will be maximum. When the load is purely resistive, no phase difference among voltage and current, then the output electrical power can be expressed as [5]:

$$P_{electrical} = \sqrt{\frac{3}{8}}\frac{V_{out}^2}{R} = \sqrt{\frac{3}{8}}\frac{SF_{Step}^2}{n^2 R(MS^2 + f_V S + K)^2} \quad (5)$$

From equation (4) and (5), the transient power and the efficiency of a piezotile can be observed easily. Eventually, the whole efficiency of a piezotile can be intended from Equation 6.

$$\eta_{tile} = \frac{p_{electrical}}{p_{footstep}}\% \quad (6)$$

B. Effects of Foot Stress on Proposed Piezotile

The force of gravity is mathematically represented as, $Fa = mg$. Where m is mass on the earth and g is the acceleration of gravity. The acceleration of gravity is approximately 9.8 m/s^2. Installing piezotile near or a little distance from the earth's surface, it does not put any impact on the acceleration of gravity, it's negligible. When we use piezotile on foot overbridge, the distance (4-5m) puts zero impact on the acceleration of gravity.

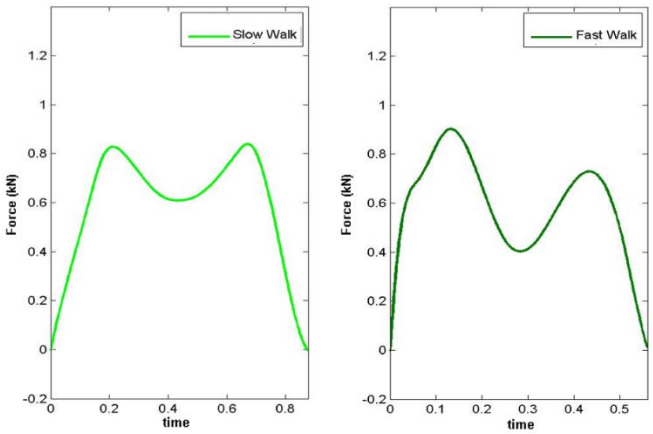

Fig. 3. Foot Stress on the piezotile at slow walking and fast walking time [6].

Fig. 3 shows the resulting force delivered to the piezotile by footstep. The waveforms observed when walking at a slow pace and a fast pace. The peak foot force is seen to approach 0.8kN at a slow pace. The peak force is seen to approach 0.9kN. As mentioned earlier, The 7 watts yielded per step stated by the Pavegen experiment was the output of the step pressure exerted by a 150-pound man (68.04kg) [1].With a gravitational acceleration of 9.8(m/s^2) that mass of the piezoelectric subject is,

$$M_p = 68.04 * 9.8 = 666.78\ N.$$

A study on the average walking speeds of subject's variable, found that the average speed of 4.52 feet per second and an average startup time of 3.39s to reach that speed, then the acceleration rate (a) is 1.33ft/s^2. The calculation can be expressed as [1]:

$$a = \frac{v_f - v_i}{t} = \frac{4.52\ ft/s - 0\ ft/s}{3.39s} = 1.33\frac{ft}{s^2} \quad (7)$$

Given the calculated mass and acceleration of walking on the piezotile subject, a force per step can be calculated as;

$$Force = M_p * a = 666.78\ N * 1.33\ ft/s^2 = 889.68\ N \quad (8)$$

So the assumption can be made that a walking person exerts 889.68N of force per step, which is similar to the force of a walking step shown in the time wave charts of Fig. 3 at around 0.8 to 0.9kN. So it is safe to say that 889.68 Newton of force generates 7 watts of energy or 127.10 Newton per watt [1].

III. Analysis and Assessment of Simulation

To analyze the mechanical system of piezotile in Fig. 2 converts to the electrical equivalent circuit [7]. This is the fair technique to analyze the piezotile. Equation (1), shows the transfer function of a single piezotile which is utilized to analyze the piezotile. The output voltage is observed by the response of the input signal by simulating the time response of the piezotile circuit model. For instance, we have totaled the output voltage for resistance value, $fv = 100m\Omega$, inductor value, $M = 1H$ and capacitor value, $K = 60mF$.

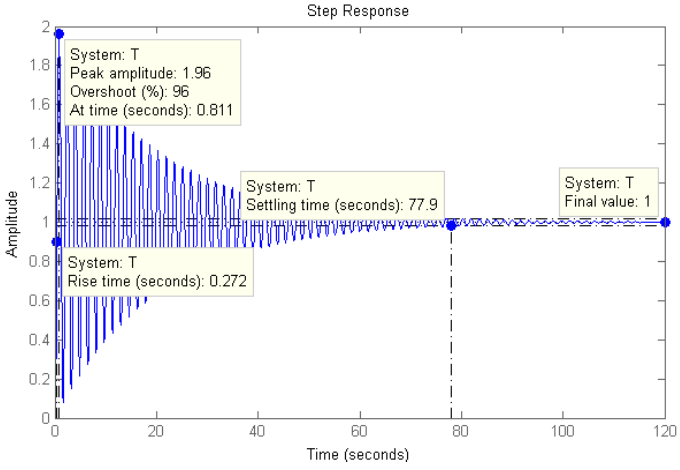

Fig. 4. The step response of the Piezotile.

Fig. 4 shows the plot of the step response of an arbitrary dynamic system model of the piezotile. The peak amplitude (A=1.96v), peak time (t_p=0.811s), rising time (t_r=0.272s), normal frequency (ω_n=1), Restraining ratio (ζ=0.0033), Relaxing time (t_s=77.9s), and percentage of overshoot (%os=96) is observed and simplified in Fig. 4.

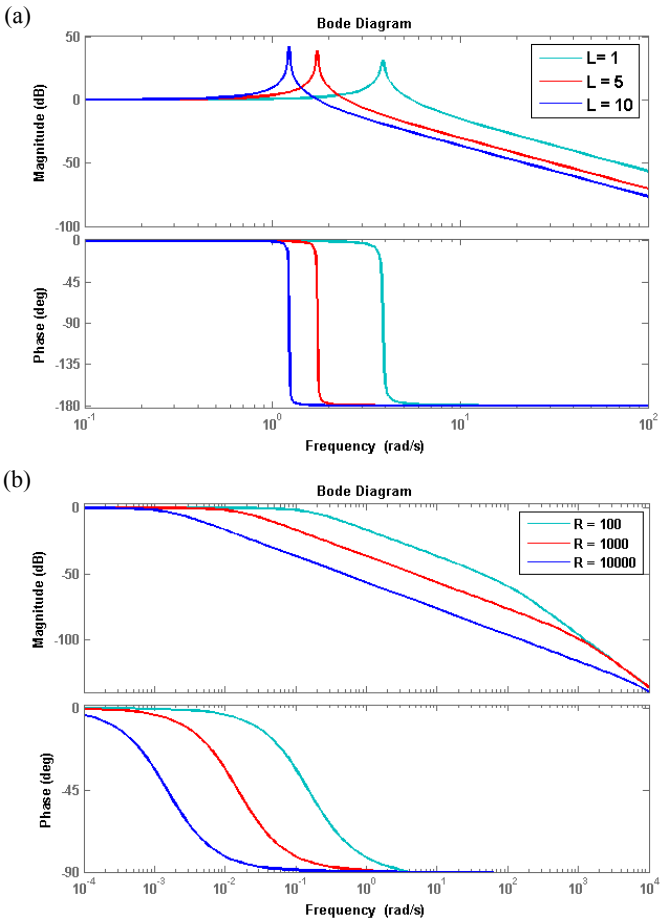

Fig. 5. The frequency response bode diagram of the electrical circuit model of piezotile with (a) several **L** values and (b) several **R** values.

In Fig. 5 shows the frequency response bode diagram of the electrical system, influenced by the different resistance (*R*) and the inductor (*L*) values. While the value of L is increased then the magnitude of the harvested energy is increased and while the value of R of the system is increased then the magnitude of the harvested energy is losses. R and L signifies the viscous damper of piezotile and mass via foot forced on the piezotile respectively. If the oscillatory system or damping is an underdamped condition ($\zeta<1$) and foot stress on the tile is increases then we get maximum output energy.

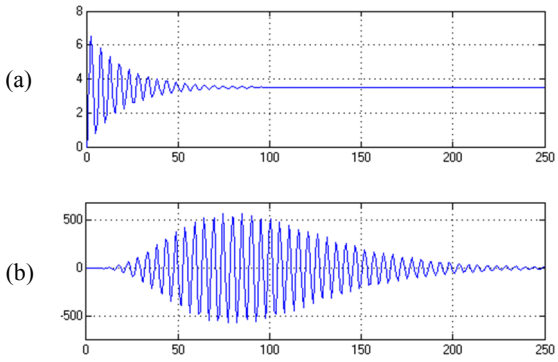

Fig. 6. The step response of (a) parallel connected and (b) series connected numerous piezotile.

Numerous piezoelectric transducer is generally connected in series or parallel connection. In a series connection, piezoelectric layers have opposite polarization directions, which produce a larger voltage output, but lower current output and parallel connection piezoelectric layers have the same polarization directions which produce in a larger current output, but a lower voltage output [8]. In figure 6, shows the step response of series and parallel connected numerous piezotile, between them parallel connected tile has more stable.

A. PID Controller for The Expeditious Stability of Piezotile.

PID control is a usual and easy control approach, which is used to make the system stable, overcome creep and vibrations, improvement of the steady state error, provide high gain feedback and enhance the tracking accuracy in the piezoelectric transducer based piezotile.

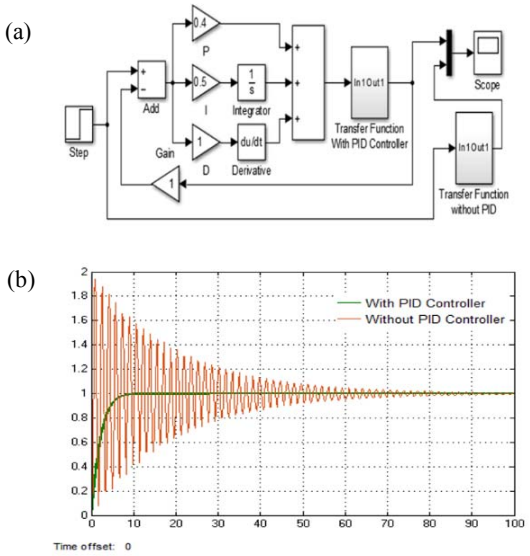

Fig. 7. The block of dynamic simulation model: (a) The entire model simulation in Simulink (b) Magnitude in time response with and without PID controller.

In PID controller, tune up the P, D and I gain for the steady oscillation and fixed the point for desired oscillations respectively. After using the PID controller, the system response is more stable than the underdamped conditions. As a result, the output power gain, the fastest responsibility, accuracy and reliability is increased. The results in Fig. 7 provide insight into the PID stabilization and offer convenience for the tuning of PID controllers.

B. Installation cost

Types of Piezoelectric technology were classified according to the uses, features and technical specification. Many types of piezoelectric technology used for harvesting energy.

TABLE I. PIEZOELECTRIC TECHNOLOGY TYPES AND PRICE [9].

Company Technology	Generated Energy	Price (US-Dollar)
Sustainable Energy Floor	30 W	$851
Waynergy Floor	10 W	$277
Pavegen Tile	7 W	$76
Electro-Active Polymers	1 W	Unknown
$BaTiO_3$	$7mW/cm^3$	Low Cost

POWER Leap PZT	0.5 mW	Unknown
Drum Harvesters Piezoelectric Ceramics	2.463 mW	$28

For the different feature, cost and technological reason pavegen tile is more capable and further cost-effective to generate energy as a piezotile. Pavegen tile is also lucrative and suitable to equate with other green energy and other power generation sources. Fig. 8 compare pavegen tile with other power generation sources.

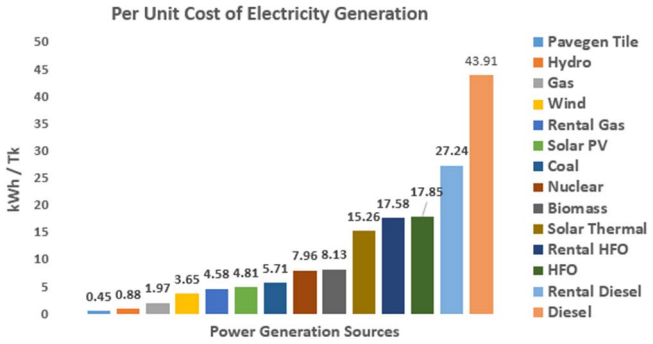

Fig. 8. Piezotile, green energy and other power generation sources per unit cost to generate electricity [10].

C. Observation of Foot Overbridge & Power Calculation

We observe a footbridge (e.g. Farmget Foot Overbridge, Bangladesh) length = 60m and width = 2.5m. The area of the foot overbridge,

$$A = Length * width = (60 * 2.5) = 150 \text{ sq. meters } (m^2).$$

TABLE II. FOOT OVERBRIDGE USER PER MINUTE [11]

Status	Number of people in (5min)	In every Minute
User	470	470/5=94
Non-User	3	3/5

We stated one piezotile for calculation purpose (e.g. Pavegen tile), One Pavegen tile being 17.1" x 23.6" inch. Then Area,

$$a = (17.1*23.6) \text{ Inches} = 403.56 \text{ sq. in}^2 \text{ or } 0.26 \text{ sq. m}^2.$$

So total piezotile need, $(150/0.26)$ sq. $m^2 = 576$ pieces.

Pavegen employees have been reported as saying the titles could cost as little as $76 in the future [9]. Initially, the installation cost is higher but output power will be more efficacious. The distance covered by a single step assuming a stride length of 0.762 meters [12]. One people covered 0.762 Meters equal to 1 Foot Step.

Therefore, one people covered 60 Meters = *79 Footsteps.*

When 94 people pass foot over bridge per minute (TABLE II), then total footsteps;

$$= (\text{Number of people} * \text{Footstep})$$

$$= (94*79) = 7{,}426 \text{ foot Steps/minute.}$$

Piezotile can produce an average of 7 watts per step then, Total Power,

$$P = 7{,}426 \text{ steps} * 7 \text{ watts} = 51.98 \text{ kW.}$$

Power developed for 60 minutes (1 hour),

$$P = 51.98 \text{ kW} * 60 \text{ minute} = 3.119 \text{ MW/h (approx.)}$$

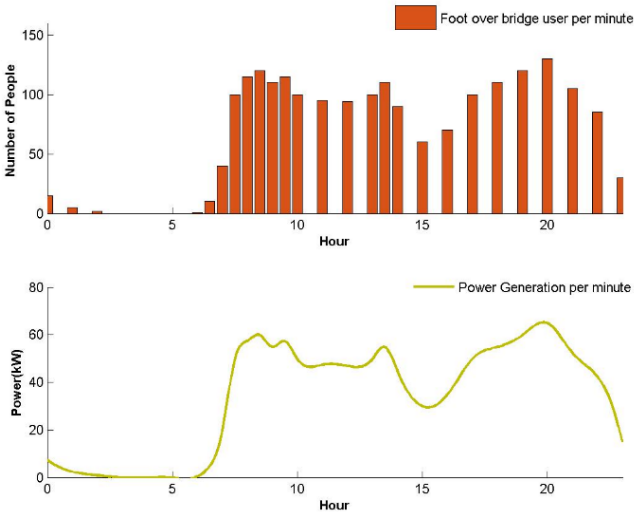

Fig. 9. The waveforms observed when (a) Number of people per minute (b) Power generated per minute.

It is an observed power generating from this curve with respect to time. Observe that from 6 a.m. to around 11 p.m. power is generating. The peak power is seen around from 7-10am, again from 1-2.30pm, and again 5-10pm, from this period maximum usage of the footbridge is observed. In this period, we get maximum power around 60kw and around minimum 30kW power is generated from the pavegen tile. In addition, average 35kW prevails.

D. Environmental Assessment

Piezotile is an environmentally amiable replacement of the burning of fossil fuels; liberate carbon dioxide, which is the leading greenhouse gas, contributor to global warming.

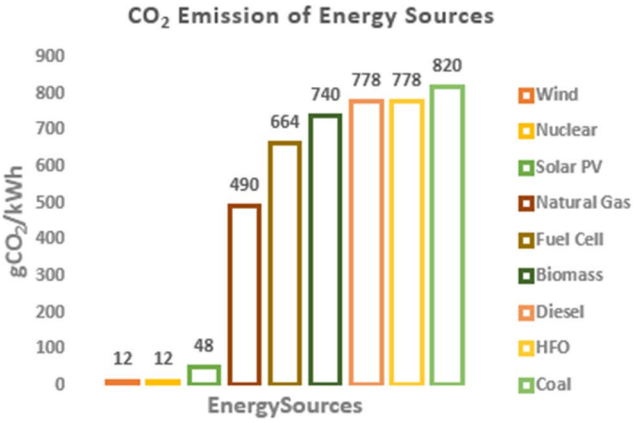

Fig. 10. Carbon Dioxide Emission of various Energy Sources

In various investigation on energy generating tiles piezoelectric transducer that energy produces in its lifetime can save approximately 0.28 ton of CO_2 [13] or emissions

savings of over 10,500 kgCO_2/year [14]. Fig. 10 shows the report on "Global warming potential and emission of CO_2 for selected electricity sources, IPCC, 2014" [15]. Piezotile is capable to produce energy which savings other sources CO_2 emission that is very important and essential for our Environment. In large crowded cities and potential locations where the tiles can be placed and more efficient in the field of renewable energy where electricity can be generated.

IV. CONCLUSION

Piezotile is superior in characteristic, a single piezotile that has the capability to produce enormous energy. It is shown the installation of piezotile on foot over bridge, which is an innovative product; capable of generating a huge amount of power is another way of Renewable energy. In a dense area, if piezotile based foot over bridge is implemented people will be highly benefited and the proper usage of foot stress waste energy.

***Abstract*— This paper represents the analysis of structural and optical properties of CZTS films grown by dip-coating and its application as an absorber in thin film solar cells. The CZTS thin films were prepared in ordinary glass substrates for a different number of depositions. The optical band gap and absorption coefficient of a CZTS absorber layer related to the concentration of aqueous precursors containing copper (II) chloride dehydrate ($CuCI_2.2H_2O$), zinc (II) chloride ($ZnCI_2$), tin (II) chloride ($SnCI_2$) and thiourea ($CS(NH_2)_2$) were determined. The solution was prepared by dissolving cation metal salts and thiourea in 2-methoxyethanol and monoethanolamine. It is observed that two times deposited film shows good quality Kesterite structure of CZTS is revealed by the XRD. Optical identifications have been carried out using UV-Vis spectroscopy techniques. The direct band-gap of 1.48 eV was found in one sample which is very close to the optimal value as an absorber layer and absorption coefficient was found greater than 10^4 cm^{-1} which establish the characteristics of leading CZTS phase in the film.**

Keywords*— Cu_2ZnSnS_4, Thin films, Dip-coating method, Sol-gel, Annealing, Band gap, X-ray diffractometer.

I. INTRODUCTION

In Thin-film solar cells industry, among various compound material, Polycrystalline cadmium telluride (CdTe), copper indium diselenide (CIS), and copper indium (gallium) diselenide (CIGS) are being utilized for materialistic purpose. Due to restrictions on heavy metal usage for Cd and scarcity of In and Te have raised concern about limitations on fabrication capacity of the PV devices. To resolve this issue, it is necessary to develop another light absorber materials that are both nontoxic and simply available. In this situation, Cu_2ZnSnS_4 (CZTS) quaternary semiconductor compound has flourished as one of the promising candidate.[1] CZTS, as an auspicious thin-film solar-cell material, has drawn great attention in the past few years [2-4]. CZTS kesterite structure has a high absorption coefficient and a direct band-gap of (1.4-1.6 eV), which is reported in previous literature [5]. Furthermore, all the elements in CZTS are non-toxic and earth-abundant [6-9].

Sol process is correlated with the sol-gel method since after producing the solution, a consecutive gel can be formed in one-step. Definition of the sol-gel is as follows: "Formation of an oxide network through polycondensation reactions of a molecular precursor in a liquid" [10]. The final particles can be amorphous or crystalline. Generally, the sol or colloidal suspensions of particles are ruled by the Van der Waals forces or hydrogen bonds. The basis of sol-gel synthesis is to dissolve a precursor compound in a liquid and bringing it back as a solid in a regulated manner [10, 11]. Multi-component systems with a preferred stoichiometry by mixing sols of different compounds can be achieved by Sol-gel synthesis [12]; preventing problems of precipitation and intimate mixing of reagents at the atomic level by producing small particles. The conductivity of semiconducting junctions provides the basic diode mechanism, which coupled with the sensitivity to light and heat and variable resistivity is the main property used to build photovoltaic cells [13,14]. A traditional dyeing method of speedy deposition of polymer films over a large region is the Dip coating process. Dip coating means submerging of a substrate into a tank containing coating material, removing the piece from the tank, and allowing it to drain. The process is performed maintaining precise speed fulfilling controlled temperature and atmospheric conditions. The viscosity of the liquid, the dipping speed, the congeal content are some of the factors used to calculate the coating thickness. Because of simplicity, this method highly depends on automation. Many factors contribute to determining the final state of the dip coating of a thin film [15]. Heterogeneous types of dip-coated film structures and thicknesses can be fabricated by controlling many factors such as submersion time, the number of dipping cycles, solution composition, concentration and temperature, and environment humidity. The dip coating technique can give uniform, high-quality films even on bulky, complex shapes[16].

II. EXPERIMENTAL DETAILS

The sol-gel solution for CZTS precursors was prepared by dip coating and solution containing copper(II) chloride dehydrate ($CuCI_2.2H_2O$) (l.69M), zinc (II) chloride ($ZnCI_2$) (0.90M), tin (II) chloride ($SnCI_2$) (0.787M) and thiourea ($CS(NH_2)_2$) (6.665M), dissolved in 2-methoxyethanol. The mixture was stirred on the hotplate and magnetic stirrer at 45-55 °C for ½ hour. Meanwhile, the mono-ethanolamine were added (a few drops as a stabilizer). Then, the mixture incubated at room

temperature at least 24 hours to yield a homogenous and transparent yellow solution. Lastly, the yellowish mixture from the sol-gel process was fabricated on SLG (soda lime glass) substrates. The glass substrates were cleaned through methanol solution and after that DY water. Dip coater, PTL-MM01 was used to deposit the CZTS film on the cleaned soda lime glass substrates for withdrawing speed about 150 mm per minute. Then the wet films have been dried on an oven at 200 °C for 10 min. Sample is put into the environment for natural cooling after drying. The process was repeated about 1 and 2 times. The sample name is denoted by A-1 for one time dipped and A-2 for two times dipped. Fig. 1 represents sample A-1 and A-2.

Fig. 1. Fabricated samples of 1 and 2 times deposited CZTS thin Film

After that, the samples were annealed at 250°C for 15 min. The phases and crystal orientation analysis were identified by using X-ray spectrometer with Cu Kα1 radiation (λ = 1.5406 Å) collected from 2θ = 22°- 60°. The optical absorption and optical band gap is calculated by transmittance spectra on the wavelength range of 400 – 1200 nm measured by UV Vis spectrophotometer. The thickness of the samples was measured through Stylus profiler in this research work.

III. RESULTS AND DISCUSSION

A. Structural properties

Fig. 2 exhibits the XRD patterns of sample A-1 and A-2 of CZTS films prepared by dip coating technique. Broad peaks were obtained at the 2 Theta positions 28°, 47.40° and 55.40° for the films which corresponds to the (1 1 2), (2 2 0), (3 1 2) planes of CZTS thin films and they are distinct characteristic of tetragonal type kesterite structure of CZTS (ICDD card no: 26-0575)[17]. In Fig. 2, the films annealed at 250°C were identified by using XRD as a kesterite CZTS compound with Zn_2SnO_3[18] which corresponds to the (2 0 0) and (2 2 0)planes. The films revealed poor adhesion to the substrate because of the low temperature of annealing.

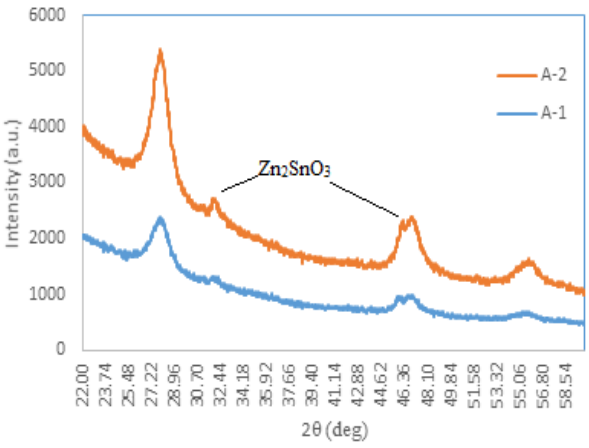

Fig. 2. XRD pattern of samples A for 1 and 2 times deposited CZTS film

B. Optical properties

The optical properties were calculated by taking on UV Vis spectrophotometer the transmittance spectra shown in Fig. 3 for 1 and 2 times deposited film which is recorded for wavelengths of 400 to 1200 nm. It has been observed that the two samples exhibit poor transmittance in the visible region for low-temperature annealing.

In the case of CZTS thin film absorber layer, low transmittance is desired so the samples variation were usually the same in transmittance vs wavelength curve. The other optical characteristics manifested variation so comparable result can be found.

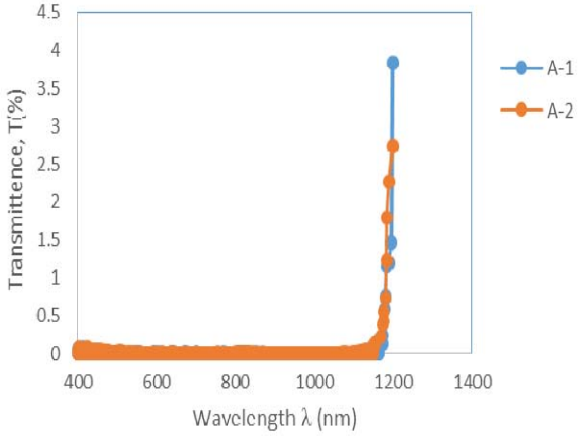

Fig. 3. Transmittance Vs Wavelength of 1 and 2 times deposited CZTS thin Film

The absorption coefficient (α), of CZTS films, was assessed from the transmittance data as demonstrated in Fig. 4[19].

$$\alpha=(1/d)\ln(1/T) \quad (1)$$

Where d is film thickness and T is transmittance. The absorption coefficient is $10.3x10^4cm^{-1}$ and $6.9x10^4cm^{-1}$ respectively of samples A-1 and A-2. The absorption

coefficient for different layer decreases with increasing depth.

The optical band gap of CZTS films is calculated as shown in Fig. 5 from the accordance to Tauc's formula [20].

$$(\alpha h\upsilon)=A(h\upsilon-Eg)^{m} \quad (2)$$

Where A is a constant, the exponent "m" can take values ½ for direct allowed, 2 for indirect allowed, 3/2 for direct forbidden and 3 for indirect forbidden. The band gap energy was enumerated by plotting $(ahv)^2$ versus the hv in Fig. 5, therefore, the direct band gaps (Eg) of CZTS annealed at 250°C during 15 minutes were estimated to be 1.40 eV and 1.48 eV respectively of samples A-1 and A-2. The band gap energy was found to be near 1.5 eV, which is in good agreement with previously reported value [21].

The band gap increases with the increase in thickness. It is found that the band gap of sample A-2 is near to the optimum for photovoltaic applications.

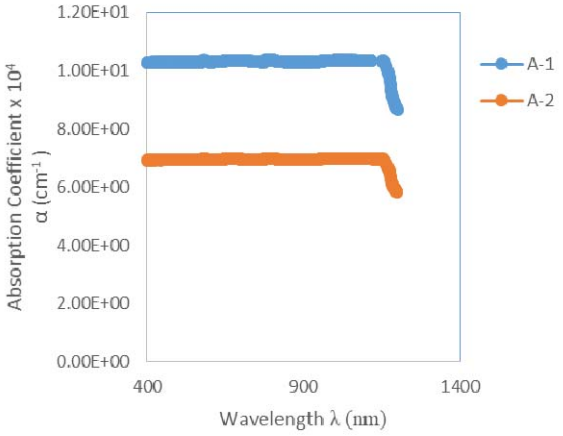

Fig. 4. Absorption coefficient of A-1 and A-2 layered CZTS thin films as a function of wavelength λ

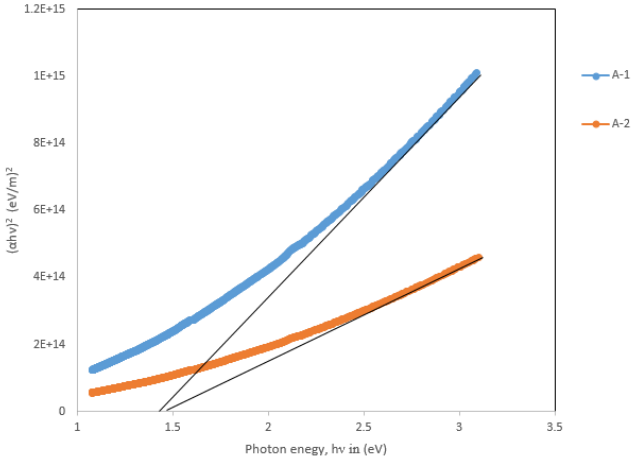

Fig. 5. The values of the energy gap $(\alpha hv)^2$ in terms of hv of CZTS thin films

TABLE I. OPTICAL PROPERTIES OF CZTS WITH VARIOUS LAYER

Sample name	A-1	A-2
Thickness (μm)	1.92	2.85
Optical band gap (eV)	1.40	1.48
Absorption coefficient(cm^{-1})	$10.3x10^4$	$6.9x10^4$

The extinction coefficient (k), was determined from α using the following relation [22]

$$\kappa=\alpha\lambda/4\pi \quad (3)$$

It is seen from Fig. 6 that the extinction coefficient ranges between the extremes of 0.228 and 0.917 for the samples of A-1 and A-2 layer in the wavelength range of 400- 1200nm. The behavior of curves appears to be related where the value of "k" increases with increasing wavelength. as "k" is directly proportional to the absorption coefficient (eq.3). Also, since the absorption coefficient of the CZTS is very high (>10^4 cm^{-1}), so "k" will be high.

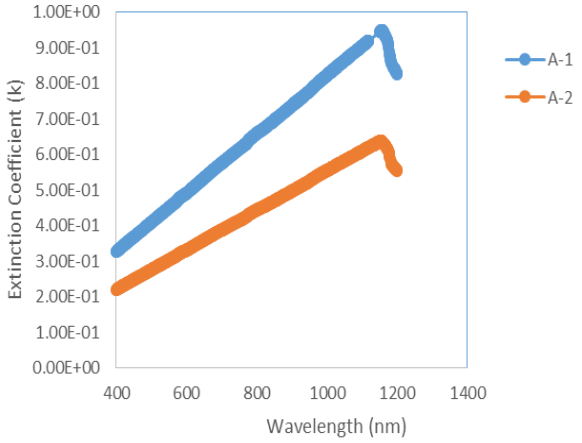

Fig. 6. Extinction coefficient of A-1 and A-2 layered CZTS thin films as a function of wavelength

IV. CONCLUSION

This research was observant to the synthesis and characterization of non-stoichiometric Cu_2ZnSnS_4(CZTS) absorber layers. Dip coating technique and anneal at air atmosphere had proclaimed to be convenient for kesterite CZTS thin film composition. The films exhibit poor adhesion to the substrates because of low annealing temperature. Several impurities are the cause of the secondary phase in the films. Here, the number of layers were varied and sample A-2 had a bandgap energy of 1.48eV which is suitable for photovoltaic applications. The X-ray diffraction displays that CZTS has a kesterite structure with a affluent orientation along the (112) plane [17]. It can be seen that the band gap increases with increase in thickness and absorption coefficient decreases at the same time. For this reason, the extinction coefficient decreases as α has proportional relation to k.

ACKNOWLEDGEMENT

***Abstract*— solar radiation (SR) is a significant parameter for producing solar power for the electric energy mix. Sun radiation data is hard to be accumulated at particular geographical location of a country due to measurement instruments is limited especially in developing country like Bangladesh. Hence, estimation of SR for a meteorological location is an important research to learn solar energy potentiality. In this regards, this paper presents a statistical inference model for the estimation of bright sunshine hour which is important metric for solar irradiance. Normal distribution model is inferred from the historical data of some important locations of Bangladesh. Mean and standard deviation are the parameters at 95% confidence interval which control the behavior of such distribution. In this statistical model, bright sunshine hour is estimated that expedite to find the potential of solar energy at particular location. The estimation model can be used as a decision making support to design photovoltaic power system for deployment of energy mix policy.**

Keywords—radiation, sunshine hour, statistical, solar energy, energy mix

I. Introduction

Power Generation mix refers to the combination of the various primary energy sources (fossil fuels, nuclear energy, renewable energy sources) using to meet electricity according to geographical region. The composition of the electricity generation mix depends on the availability of usable resources domestically or the possibility of importing it. Country's Policy for power generation defines historical, economic, social, demographic, environmental and geopolitical factors. These differences can be appreciated by taking a look at the generation and consumption of electricity information for a country.

Bangladesh is a developing country with 162.95 million populations. Population growth annually is 1.1% with density 1251.8 per sq. km of land area. In 2016 the Electric power consumption of per capita was 310 kWh for 0.46 metric ton carbon emission per capita. Information on Bangladesh is shown in Table I [1]. Fig.1 shows power generation mix of Bangladesh from the year 2001 to 2016 [1]. There is six power generation mix used (Gas, Oil, Hydro, Coal, Renewable and Nuclear) for generating electricity in Bangladesh but nuclear yet contribute. Gas is the dominant sources, above 80% of power generation-mix in Bangladesh. Presently, Contribution of coal is less significant but there are projects to be commissioned by 2021 [2]. The Nuclear power plant will be implemented and on an operation by 2024 [3] According to World Bank, renewable energy share is small amount into generation mix included hydropower plant in 2016.

TABLE I: COUNTRY INFORMATION IN 2016

Population, total (millions)	162.95
Population growth (annual %)	1.1
Surface area (sq. km) (thousands)	147.6
Population density (per sq. km of land area)	1,251.8
CO_2 emissions (metric tons per capita)	0.46
Electric power consumption (kWh per capita)	310
Access to electricity (% of the population)	75.92%

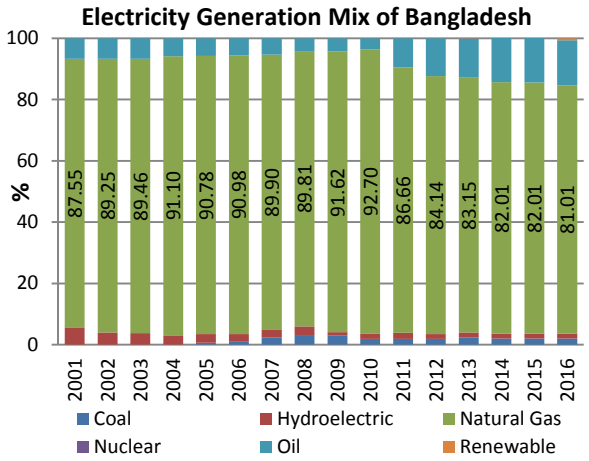

Fig. 1. Electricity Generation Mix (2001-2016) in Bangladesh

There are immense opportunities to contribute a large amount of solar energy as a "Power Generation Mix" in Bangladesh. Bangladesh is a south Asian country located in between 20.30°- 26.38° North latitude and 88.04° - 92.44° east longitude [4]. Therefore, it is an ideal subtropical location for solar energy utilization and 70% of sunlight is plentiful in the year [5]. The government has set a target to generate 2000MW of electrical power from renewable energy by 2021[6]. The new target of renewable energy would be 10% of the total electricity generation in 2021 and would increase to 20% percent by 2030 [7].

It is important to know the exact bright sun shine hour and solar energy potential at a particular geographic location. So that, solar information database can be built for research. In research, numerical and regression model was

established to calculate solar energy using sunshine hour [8] [9]. A comparative study of different types of correlation models had been done to find the solar radiation data [10] [11]. Numerical approaches using temperature base method and Weibull distribution were used to estimate solar radiation data at certain location [12]. In this paper, the historical data of bright sunshine hour at a particular geography location is analysed and applied to normal distribution to get stable bright sunshine hour. Standard deviation and error are determined how much the data stable at a particular geography location by utilizing statistical approaches. The Determinate bright sunshine hour has been applied to per kilowatt solar panel for calculating solar energy potential in the certain area.

II. Methodology

A. Setting Boundaries

Four different districts are selected for this analysis of solar energy potential. These four districts are having distinct geographical locations which are example of rest of districts in Bangladesh. These are shown in Table II [13]

TABLE II. District Geographical Location

Districts	Distinctness	Coordinates	Elevation
Hatia	Island	22°22' N , 91°7.5' E	4 m (13ft)
Rangamati	Hill Station	22°38' N , 92°12' E	11m (56ft)
Cox's bazar	Sea Beach	21°58' N , 92°01' E	3 m (10ft)
Dhaka	Town-Capital	23°42' N , 90°22' E	4m (13.12ft)

B. Research Methodology

The figure 2 presents the flowchart to simulate the research. Bright sunshine hour of different meteorological locations of Bangladesh as samples are considered to make an inference in building the statistical model. Some pre-processing such as normalization, outlier detection and missing values adjustment are applied to the input datasets in order to

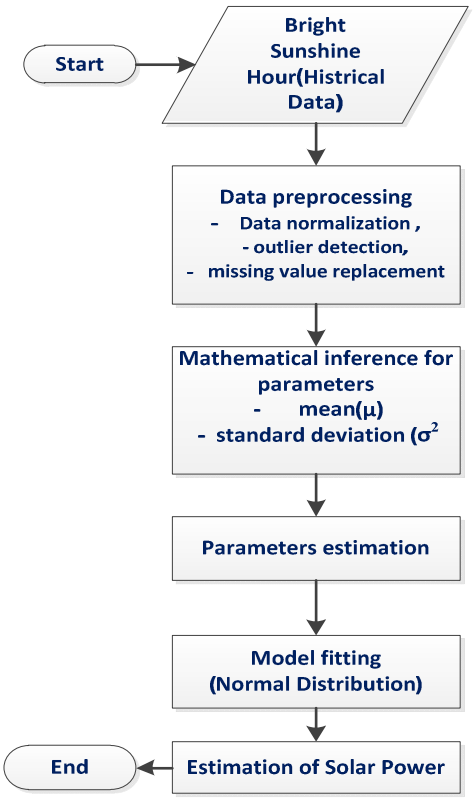

Fig. 2: Steps of Methodology

enhance the fitness of the data. To estimate the parameters (mean and standard deviation) of statistical model, mathematical inference is deducted. After estimation of those parameters, the probability distribution function (PDF) is established and fitted. Finally, solar power of every month can be estimated from the inferred model for different meteorological locations of Bangladesh.

C. Data Collection

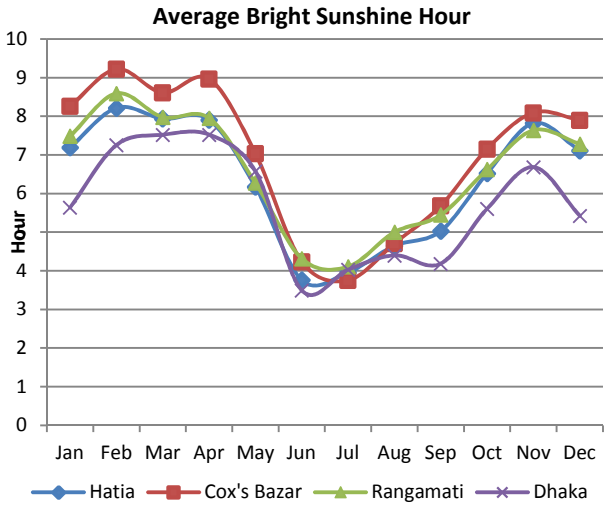

Fig. 3: Monthly average sun hour of 4districts

Bangladesh Agriculture Research Council (BARC) has developed climate information management system that is the website where are six types spatiotemporal weather data available. District wise bright sunshine hour data has been collected from climate information management system for last 13 years that is shown in figure 3 [14].

D. Statistical Parameter of Estimation [15]

Sunshine Hour (SH) is a decisive meteorological parameter for the prediction of solar energy. SH is a random variable with time which can by characterized by probability distribution function such as Gaussian or Normal distribution. The normal or Gaussian distribution is defined by the following distribution function:

$$F(SH) = \frac{1}{\rho\sqrt{2\pi}} e^{\frac{-(SH-\mu)^2}{2\sigma^2}} \quad \ldots\ldots\ldots\

Therefore, the likelihood of an outcome is mathematically defined by the following inequalities:

$$L(x_1,.....,x_n, \mu\ \sigma^2) = \prod_{i=1}^{n} f(x_i, \mu, \sigma^2)$$

$$=(\frac{1}{2\pi\sigma^2})^{\frac{n}{2}}\exp\{-\sum_{i=1}^{n}(x_i-\mu)^2/2\sigma^2\}$$

To maximise the log-likelihood, derivatives with respect to θ_1 and θ_2 are to be calculated and set to be zero and log-likelihood is given by the following equation:

$$ln(L) = -\frac{n}{2}\ln(2\pi\sigma^2) - \frac{\sum_{i=1}^{n}(x_i-\mu)^2}{2\sigma^2}$$

Performing derivatives with respect to the μ and σ^2 and setting to zero, yields the following parameter estimations:

μ (estimated mean) = $\bar{x}$ (sample mean) ……. *(2)*

$$\partial^2 = \frac{\sum_{i=1}^{n}(x_i-\hat{\mu})^2}{n} = \frac{\sum_{i=1}^{n}(x_i-\bar{x})^2}{n} \text{ ……..... (3)}$$

A confidence interval (p) covers "plausible" values of the parameter. It is a simple arrangement of the point estimate along with estimated standard error. A confidence interval is connected with a confidence level, named 1−α and which express the confidence that the parameter μ essentially lies within the prescribed confidence interval. Confidence levels of 90%, 95%, and 99% are typically used, which correspond to α values of 0.10, 0.05, and 0.01, respectively. In our experiment, 95% confidence interval is considered.

F. Calculation of Energy Production

Solar Panel 1000W at Standard Testing Conditions (STC) needs sunlight to produce the maximum solar output. The solar panel is mounted facing south and in an area where is no shaded for any reason (such as building, tree). It is important that Solar panel can be produced maximum amount of energy during at peak hours.

A peak sun-hour, specifically, is an hour during which the intensity of sunlight is 1,000 watts per square meter during a typical day. And hours of daylight is time duration of light in a typical day. The amount of solar radiation, delivered by the sun varies throughout the day, based on the sun's position in the sky, clouds, and other atmospheric conditions. So availability of energy production is calculated using equation (4).

$$Energy\ (KWh) = bright\ sunshine\ hour \times capacity\ of\ Solar\ PV\ Pane \text{……..} (4)$$

III. EXPERIMENTAL RESULT

The normal probability distribution is characterised by two parameters (mean, μ and variance, σ). In regards, mean (μ) and variance (σ) represents average distributed sunshine hour and variation of this sunshine hour for the respective location respectively. In this work, the distribution of sunshine hour is fitted by the normal probability distribution function. The parameters of this distribution are estimated by using the equation (2) and equation (3). The samples are taken from historical mean sunshine hour (SH) recorded in different meteorologically locations.

TABLE III: NORMAL DISTRIBUTION OF BRIGHT SUNSHINE HOURS (μ) VARIANCE (σ) IN FOUR DISTRICTS OF BANGLADESH.

	Hatia		**Cox's Bazar**		**Rangamati**		**Dhaka**	
	μ	σ	μ	σ	μ	σ	μ	σ

Dec	7.12	1.09	7.90	1.18	7.28	0.72	5.42	1.30

Here Cox's Bazar, Dhaka, Hatia and Rangamati are considered to simulate for the statistical model. For each month, a statistical model (normal distribution fitting) is developed with the estimation of population mean and variance at 95% confidence interval. Fig. 4 to 7 illustrates the normal distribution fit with mean and variance of September month only for those locations. And table III shows mean (μ) value (estimation bright sunshine) and variance (σ) for four districts of Bangladesh. Finally, a statistical estimation is represented solar energy potentiality in different districts in Bangladesh using the equation (4). Table IV represents minimum and maximum solar energy potential in respective location in Bangladesh. Bright sunshine is taken for minimum (μ- σ) and maximum (μ+ σ) sunshine hour from the normal distribution model. And STC condition is considered 1000W solar Photovoltaic (PV) panel for calculation monthly average solar energy production in respective location.

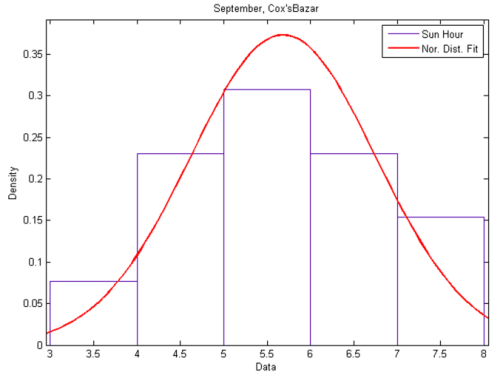

Fig. 4. Normal Distribution Fit of Sunshine Hour μ=5.68462 at standard error =0.296528 and variance σ=1.06915 at standard error =0.222933 of Cox'sBazar in September.

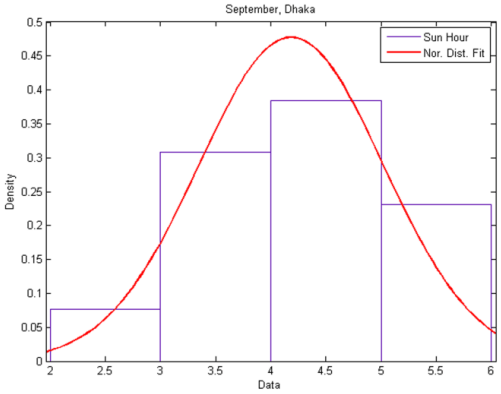

Fig. 5. Normal Distribution Fit of Sunshine Hour, μ= 4.18462 at standard error=0.231729 and variance σ=0.83551 at standard error =0.174216 of Dhaka in September.

IV. Conclusion

In solar energy technology, bright sunshine hour is the key meteorological parameter for harnessing solar energy by solar photo-voltaic (PV) panel. Estimation of solar energy from measured sunshine hour offers an important alternative in absence of measured solar radiation. This paper developed statistical model to figure out monthly approximation of sunshine duration at a particular location. The performance of each model is evaluated and compared using statistical error parameters.

Due to random behaviour of meteorological parameter, the statistical analysis has been chosen and inference models are developed from which sunshine hour can be predicted where no measuring instrument is available. This piece of knowledge could be utilized to assess solar energy potentiality of particular location. Here, four districts are randomly chosen from different geographical locations of Bangladesh to show numerical calculation of solar energy potential using MatLab. And similar study can be done for every district of Bangladesh. Government of Bangladesh is very concern now to generate power from numerous renewable energy sources such as solar, coal and nuclear as electricity generation mix policy. In this regard, this paper can be used as an artificial tool to make decisions in energy generation policy by the incorporation of solar power for green technology and, to reduce the consumption of natural gas.

***Abstract*— Currently, energy security and environmental cleanliness are becoming an important concern to the civilized world due to increasing population and global warming, which motiving the researcher towards finding the alternative energy resources instead of traditional energy source for power generation. Now, Waste-to-Energy technology (WTE) has earned a great deal of attention both the developed and developing countries for an effective waste management system. This study aiming at finding a more suitable and effective method among WTE technologies in perspective of Bangladesh's economy, energy efficiency, and environmental aspects that can sustain with our future energy demand. In this paper we initially compared different types of emerging WTE technologies and then these technologies are applied in Chittagong, a city of Bangladesh in different aspects and finally finding out that Incineration-based WTE technology is the most suitable method because of its operation flexibility, lower cost, higher efficiency, less greenhouse (GHG) emissions, and simplicity in design on here. Thus, the energy produced in this method can contribute significantly to reduce our electricity shortage with an effective waste management system and can be a building block of a green-smart city.**

Keywords*— Energy security, Environmental cleanliness, WTE technology, Bangladesh, Incineration, Green-smart city.

I. INTRODUCTION

According to the International Energy Agency, about 22% of the global population lacks energy access [1]. Also, an average of 34% of people in developing countries lack of waste collection service and the waste generation rate is expected to double by 2025 [2]. Moreover, Bangladesh is a developing country with a large population where only 75.92% of people have electricity access and facing load shedding problem due to its gradually increasing power demand [3].

Waste generation in big quantities and lack of appropriate waste management system is one of the most important issues in the present world. Waste-to-Energy technology (WTE) is an emerging technology of the currently developed country. It can also be a good solution for the scarcity of electricity as well as the management of solid waste in Bangladesh. We know that waste everywhere needs urgent disposal which requires manpower, cost, and proper space; so waste management is a challenge for the government and city authority. Many developed countries such as the UK, Middle East, USA, and Venezuela, etc. have already adopted WTE technology for waste management and to produce significant energy from waste [4-5]. Waste-to-Energy (WTE) technologies consist of any waste treatment process that creates energy in the form of electricity, heat or transport fuels from a waste source [6]. WTE technology produces energy using waste as a feedstock. Waste is generated at a large extent in our day to day life. We just throw away this wastes and the governing authority collects them. Instead, if these wastes are utilized using WTE technology then a large amount of energy can be produced. This generated energy can contribute to the growing power demand in a highly dense populated developing country like Bangladesh where waste generation rate is very high. The waste management system should not be only limited to energy and heat production but it should also be environmentally sustainable and cost-efficient. Therefore, determining a more suitable WTE technology in the perspective of Bangladesh is a great challenge.

In this research paper we initially compared different types of emerging WTE technologies and then these technologies are applied in Chittagong in different aspects and finally finding out that Incineration-based WTE technology is the most suitable method because of its feasible surroundings in economy, energy efficiency, and environmental circumstances in perspective of the present conditions of Chittagong city that can sustain with future energy demand. Thus, the energy produced in this method can contribute significantly to reduce our electricity shortage with an effective waste management system and can be a building block of a green-smart city.

II. OVERVIEW OF EMERGING WTE TECHNOLOGIES

WTE refers to the production of Electricity, Heat and Biomass gas from Municipal Solid Waste. Currently emerging WTE technologies used worldwide for energy generation are mainly [7] —

(a) Incineration
(b) Gasification
(c) Anaerobic Digestion
(d) Landfilling.
(e) Pyrolysis.

The main features of these WTE technologies are summarized in the Table I [8].

Within the given WTE technologies, there have certain differences among themselves. We consider here based on the design maximization, requirement of oxygen, treated flue gases and material handling and preparation processes. The major Key differences between WTE technologies are stated in Table II [9].

Net Energy Generation Potential per Ton MSW of Incineration, Gasification, Anaerobic Digestion and Landfilling is given in the Table III [10].

TABLE I. MAIN FEATURES OF WTE TECHNOLOGIES

Incineration	Gasification	Anaerobic Digestion	Landfilling	Pyrolysis
Thermal Conversion	Thermo-chemical Conversion	Biochemical Conversion	Biochemical Conversion.	Thermal-chemical Conversion
Compete oxidation of waste matter	Partial Oxidation of waste matter	Enzymatic decomposition of waste matter	Partial Oxidation of waste matter.	No oxidation process is used.
End product is steam which is used to produce electricity	End product is syngas. Syngas is primarily CO and H_2. Syngas is used to produce electricity	End product is Methane gas which is used to produce electricity	The end product is ignitable methane gas which converts into gas engine and finally into electricity.	End product is Char, bio-oil and syngas. Syngas is used to produce electricity.

TABLE II. MAJOR DIFFERENCES AMONG WTE TECHNOLOGIES

Incineration	Gasification	Anaerobic Digestion	Landfilling	Pyrolysis
Designed to maximize the conversion of feedstock to CO_2 and H_2O	Designed to maximize the conversion of feedstock to CO and H_2	Designed to maximize the conversion of feedstock to CH_4	Designed to maximize the conversion of feedstock to CH_4 to CO_2.	Designed to maximize the conversion of volatile organic product into low molecular weight gas & char.
Large quantities of oxygen needed	Limited quantities of oxygen	No oxygen needed	No oxygen needed.	No oxygen needed.
Treated flue gas discharged to atmosphere	Treated syngas used for chemical production and power production	Treated flue gas is used at some extent but CO_2 is discharged to atmosphere	Treated flue gas and discharged CO_2 to the atmosphere.	Treated syngas used for power production.
Material handling and preparation is complex	Material handling and preparation is simple	Material handling and preparation problems can arise	Material handling and preparation is complex enough due to the large area requirement compared with others.	Material handling and preparation is complex.

TABLE III. ENERGY GENERATION POTENTIAL PER TON MSW

Technology	Energy Potential (KWh per ton MSW)
Incineration	585
Gasification	660
Anaerobic Digestion	250
Landfilling	105
Pyrolysis	660

III. CASE STUDY-CHITTAGONG, BANGLADESH

In WTE technologies, Municipal Solid Waste (MSW) is used as feedstock. In this study, Chittagong city of Bangladesh is considered for implementation of WTE technology. Chittagong is the second largest city and commercial capital of Bangladesh with a large population. The area of Chittagong City Corporation is 155.4 Sq. km located in between 22°13' and 22°27' north latitudes and in between 91°40' and 91°53' east longitudes. The total Population of Chittagong city corporation was 25, 82,401 in 2011 including the floating population 5, 42,965 according to the information from Chittagong City Corporation's website [11] and in 2015 this amount exceeds on 32, 09, 650 [12]. In the Chittagong area, the demand for power is around 1,000 MW, but the grid provides only 700 to 750 MW [13]. So it is very much necessary to produce more power in order to meet this demand. For the design topology boost up we consider the Municipal Solid Waste for five days at a stretch of Chittagong City in 2018 which is shown in "Figure 1".

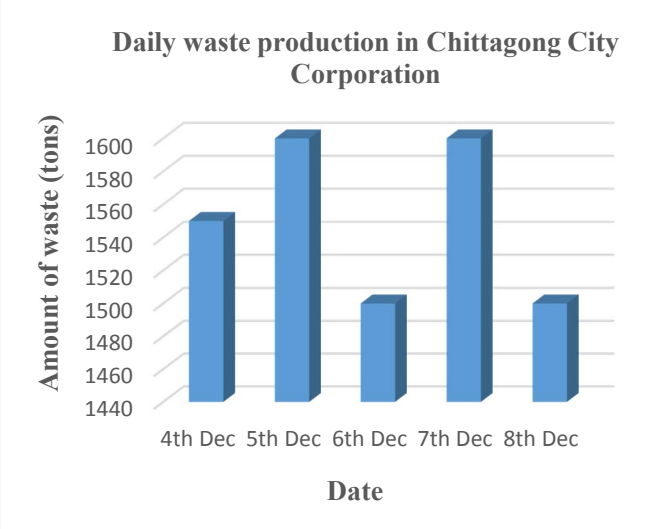

Fig. 1. MSW production in Chittagong city for five days

" Figure 1" provides that the average amount of waste produced in Chittagong city is near about 1550 tons in which we collected the real-time waste production data physically. Satyajit Roy Das et.al. Showed a clear practical analysis about the actual amount of Solid Waste management named after as "Solid Waste Management in Commercial City of Bangladesh" by the Chittagong City Corporation authority and from their analysis we consider here the amount of waste collection is 958 tons per day [12]. There are several types of waste are produced in Chittagong city. The food wastes are the main components of them. The characteristics of MSW of Chittagong city is presented in Table IV [14-16].

"Figure 2" shows the pie chart of typical MSW characteristics of Chittagong city based on the values of wet weight function from Table IV.

MSW generation can be calculated for the perspective city using equation (1) as Historical Trend [17]:

$$PWG = \frac{(PBY + PBY * AGP) * (PCWB + PCWB * AGW) * 365 * 1}{1000} \ldots\ldots (1)$$

Here, PWG is represented as projected wastes generation in a year (tons). Also, PBY, AGP, PCWB, and AGW represent the population in the baseline year, an annual growth rate of population, per capita wastes generation in the baseline year (kg/cap/day) and average growth rate in the per capita waste generation respectively.

TABLE IV. TYPICAL MSW CHARACTERISTICS IN CHITTAGONG CITY

Material	Wet weight fraction (%)	Moisture content (%)	Dry weight fraction (%)
Food wastes	70	74.86	17.60
Plastic	5	0.61	4.97
Paper	10	3.60	9.64
Grass & straw	2	34.18	1.32
Glass & ceramic	1	0	1.00
Metals	4	0	4.00
Textiles	5	7.3	4.64
Others	3	7.24	2.78

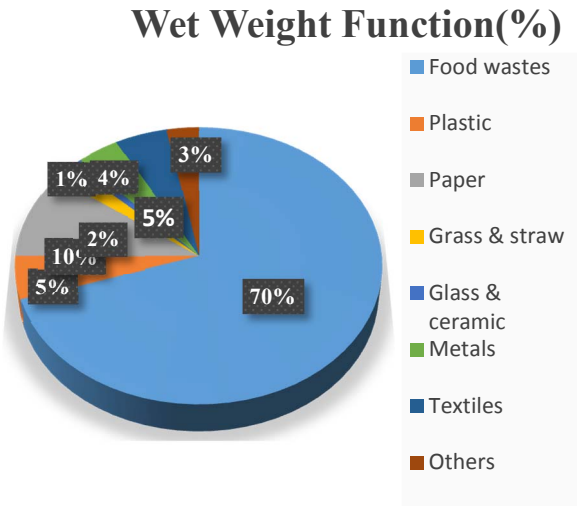

Fig. 2. Amount of different types MSW production of Chittagong city.

Table V shows the differences among various approaches of WTE technologies applied in Chittagong city considering the Case study information, Total cost, and MSW conversion and emission factor. In terms of case study information, we consider waste feed 958 tons/day here in every technology from produced 1550 tons/day according to the information from Satyajit Roy Das et.al [12]. Besides this average distance from transfer point to hub consider here 7 km and also the data's related to vehicles which are used to convey the wastes are also taken from that analysis. In terms of cost parameter, we consider three types of cost here including Average plant Capacity cost (USD/ton waste), Operation and Maintenance Cost (USD/ton waste), Transportation cost (USD/km). Having said that we just have to contemplate the transportation cost in landfilling technologies, the existing method. The major feature we analyzed in Table V is the production of electricity and heat from per ton MSW for different technologies in which we can perceive that there is no electricity or heat produced from the current landfilling process.

IV. RESULTS AND DISCUSSION

By analyzing different technologies including the case study information, Total cost, MSW conversion and emission factor from Table V we determine the results for each scenario which shown in Table VI based on the study done by Satyajit Roy Das et.al [12]. They investigated only the overall data of waste production and transportation costs from each site and finally collected waste disposals to the land. But they didn't propose any effective solutions to the collected waste after dumping them to the land or any other better clarifications than landfilling. Our offerings here to provide an effective method for the management of solid waste in Chittagong city and also by producing electricity, heat and other effective matters from that disposed waste based on Energy, Economy and Environmental strictures analyzed through various emerging technologies and to mark waste as a source of energy. We also analyzed the cost from the waste collection stage to the electricity production stage.

The Advantages and disadvantages of Incineration, Landfilling, Gasification, and pyrolysis are also considered here for the analysis of energy, cost and environmental impact [18-20]. According to the information of Worcester polytechnic institute, we used here, from 1-ton waste Anaerobic Digestion method produces 1.2 m3/ton MSW [21] and for per ton CO2 production in pyrolysis methods are 1682.6 (tCO2/d) [20].

This study emphases on the management of solid waste in Chittagong city and its proper utilization by analysis the comparative studies based on the amount of Energy production, Cost perspective, and Environmental impact. We can easily understand the necessity of changing the existing waste management method known as "Landfilling" method as because it results in a huge negative cost impact of 76,140.4 USD/d including the costs of transportation, tipping fee, operation & maintenance, and also emitted near about 1000 t CO2/d. To overcome this problem we can use WTE method which is much profitable and environmentally friendly too. Based on the five consequences of WTE method applicable in Chittagong in Table-V we could prefer incineration technology in terms of energy generation which includes the production of electricity and heat. Incineration technology is capable to produce a total of 560.43 MWh/d of electricity and 1668.84 GJ/d of heat which trailed by Anaerobic Digestion is shown in "Figure 3". Though the Gasification and Pyrolysis method of technologies provides a little more power than the Incineration technology they don't produce any heat from their process. In terms of cost analysis, the favorable method is Anaerobic Digestion technology because of its lower operating and maintenance cost and the total cost is 84,369.41 USD/d. The second preferred method is incineration technology which slightly higher than anaerobic digestion technology and is near about 94,925.73 USD/d. But the other methods analyzed here is much higher than these two methods exposed in "Figure 4".

However, in considerations of environmental issues we should prefer the Gasification technology due to its higher amount of carbon mitigation and produce only 219.6 tCo2/d and it follows the Anaerobic Digestion, Incineration, and Pyrolysis which is shown in "Figure 5". Whereas Anaerobic Digestion and Incineration technology produces a marginally higher amount of CO2 than Gasification technology.

TABLE V. PARAMETERS FOR THE VARIOUS TECHNOLOGIES CONSIDERED FOR SOLID WASTE MANAGEMENT IN CHITTAGONG.

Parameter	Method				
	Landfilling	**Incineration**	**Gasification**	**Anaerobic Digestion**	**Pyrolysis**
Case study information					
Waste feed (t/d)	958	958	958	958	958
Average distance from transfer point to hub (Km)	7	7	7	7	7
Average vehicle Capacity (t/truck)	3.82				
Number of trips by vehicles	376				
Costs					
Average plant Capacity cost (USD/t waste)	14	2.1074	1.522	6.088	8.595
Operation and Maintenance Cost (USD/t waste)	10	95	115	80	115
Transportation cost (USD/km)	3.45				
MSW conversion factor					
Electricity production (MWh/ t MSW or MWh/m^3)		0.585	0.66	0.25	0.66
Heat production (MWh/ t MSW or MWh/m^3)		1.742		0.2976	
Ash production (t/t MSW)		0.1			
Biogas Production (m^3/t MSW)				1.2	
Digestate production (t/t MSW)				0.3	
Emission factor					
CO_2 emission from processing (t CO_2/t MSW)	0.791	0.28	0.2	0.253	1.7
CO_2 emission from transportation (t CO_2/km)	0.014	0.014	0.014	0.014	0.014
CH_4 emission (t/t MSW)	0.023				

TABLE VI. RESULTS FOR EACH SCENARIO BASED ON ENERGY, COST AND ENVIRONMENTAL EMISSION

Parameter	Landfilling	Incineration	Gasification	Anaerobic Digestion	Pyrolysis
Energy					
Electricity (Mwh/d)		560.43	632.28	287.4	632.28
Heat (Mwh/d)		1668.84		342.12	
Biogas (m^3)				1149.6	
Costing (USD/d)					
Capital cost	13,412	2,018.89	1,458.12	5,832.57	8,234.28
Processing (O & M) cost	9,580	91,010	110,170	76,640	110,170
Transportation cost	16,560	1,896.84	1,896.84	1,896.84	1,896.84
Total cost (USD)	39,552	94,925.73	113,524.96	84,369.41	120,274.12
Environment Emission (tCO_2/d)					
Processing Emission	757.778	268.24	191.6	242.38	1628.6
CH_4	22.034				
Transmission Emission	342	62	28	28	28
Total	1121.812	330.24	219.6	270.38	1656.6

But pyrolysis technology produces a much higher amount of CO_2 and is near about 1656.6 t CO_2/day. Analyzing the above discussion we are proposing Incineration Technology is the best solution for MSW management in Chittagong city based on the three major disputes i.e. Energy, Cost and Environment.

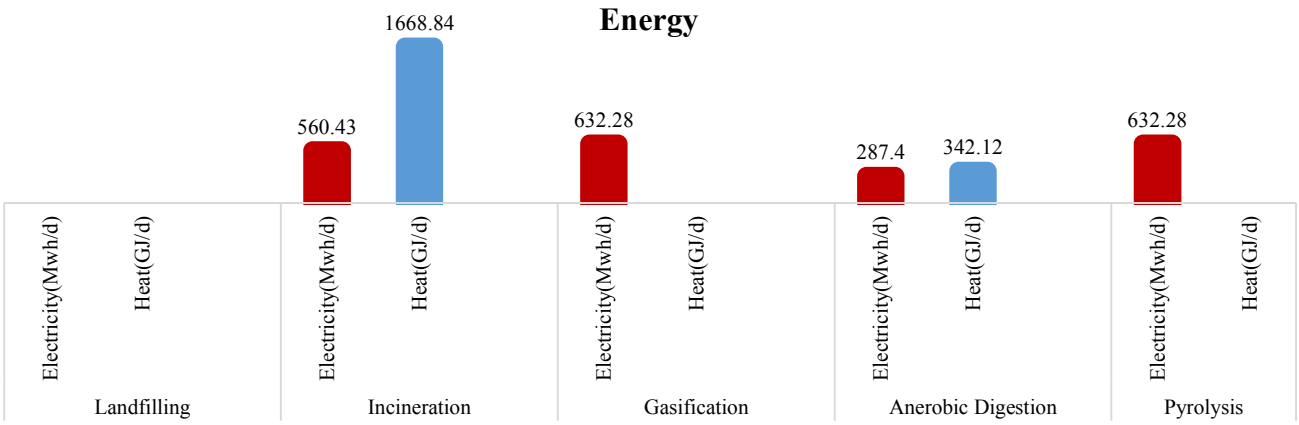

Fig.3. Energy production analysis in n different scenarios of waste management in Chittagong City.

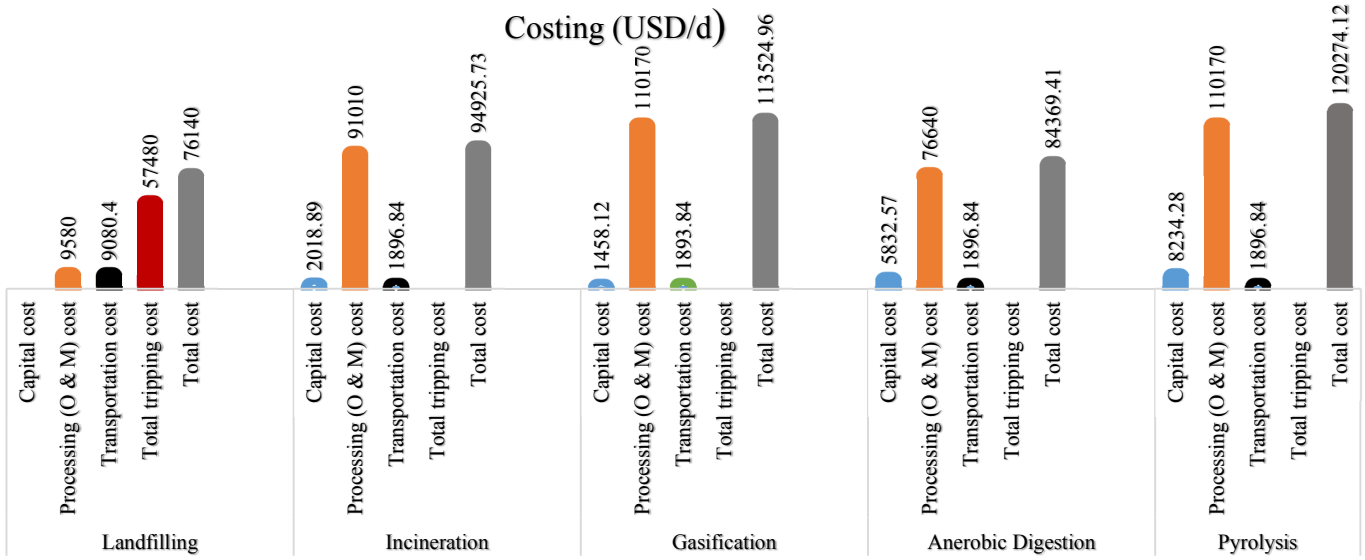

Fig.4. Cost analysis in different scenarios of waste management in Chittagong City.

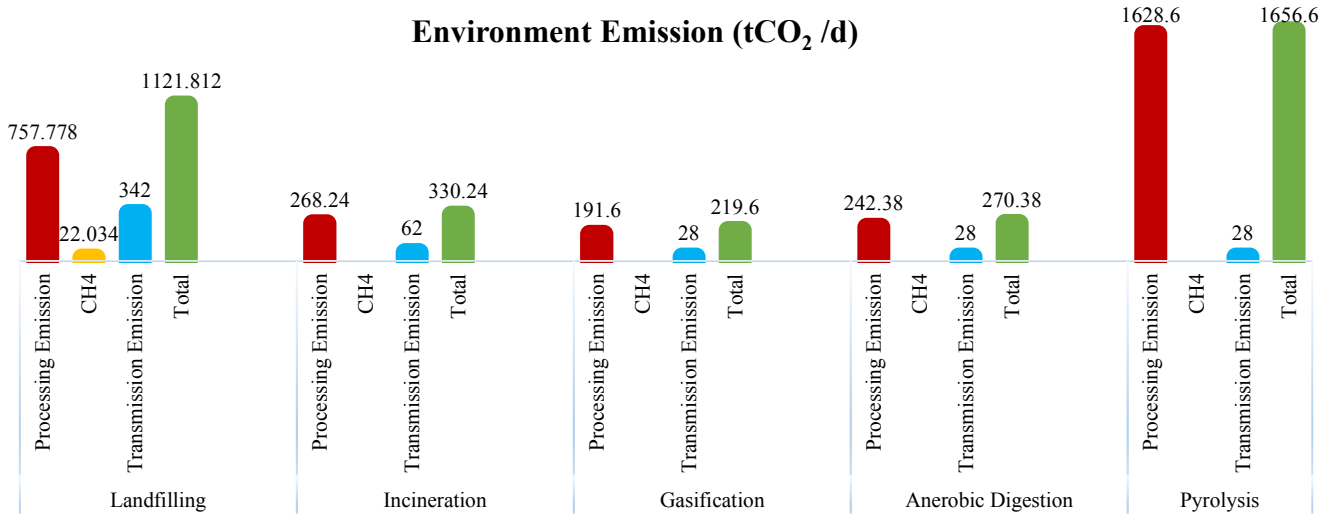

Fig.5. Environment Emission analysis in different scenarios of waste management in Chittagong City.

V. CONCLUSIONS

The municipal waste management system is always a great concern for the authority of any city and also it is much needed for them to clean it properly. In the prospect of Bangladeshi cities, the proper waste management system is still a great challenge. Besides this, the shortage of electricity in our country is still at a very high rate. According to our proposed method, the MSW can easily be managed and also the wastes can be used as a source of energy. According to the overall analysis, we can say that among all of the WTE technologies in perspective of Bangladesh Incineration is the most cost-effective, efficient, and environment-friendly method of waste-to-energy (WTE) technology. Moreover, for our future study, we are thinking to utilize the renewable sources with WTE technology to make a smarter micro grid which can be a building block for a green-clean smart city. We hope that adopting this method will help us to produce electricity using waste for our growing power demand as well as to fulfill our vision of making a green and smart city.

***Abstract*—This paper presents a detailed mathematical model of a doubly fed induction generator (DFIG) based wind turbine system. The controllers associated with this DFIG model are also derived in synchronously rotating reference frame considering Γ-Model of induction generator. A PSCAD/EMTDC simulation model has been implemented based on the proposed DFIG model. The effectiveness of this model is further verified through different case studies where the dynamic response of the implemented PSCAD model is compared with the theoretical model response. The simulation results show satisfactory performance of the proposed model and can be used for evaluation of transient stability of DFIG wind turbine system.**

Keywords—Doubly fed induction generator, grid side converter, rotor side converter, DC-link.

I. INTRODUCTION

The increasing demand of electricity is one of the greatest challenge that the modern world is facing. At the same time, the source of electrical energy has become an important concern in terms of environmental pollution and global warming which are mainly caused by burning fossil fuel in power generation. Thereby the renewable energy sources are taking over the place of conventional fossil fuel based energy generation system for obvious reasons. Among all renewable energy sources, the wind energy has become one of the prominent and dominant technology since last decade [1]. Today variable speed wind turbines equipped with doubly fed induction generator (DFIG) are widely used in wind turbine industries since energy efficiency of a DFIG based wind turbine (WT) system is a few percentage units higher than the wind turbine system controlled by full power converter [2]. In addition, the output power variations generated by wind gust can be significantly reduced in DFIG WT system compared to fixed speed wind turbine system [3]. With the large penetration of DFIG WT system, the study of reliability, ease of controllability, fault ride through capability of WT have become an important area of study. For many years the DFIG WT systems have been investigated for better performance [4][5]. In most of these cases, the simplified converters are used as controllable current sources or voltage sources which make it impossible to investigate the performance of the converters accurately. In this paper a DFIG based WT model is developed mathematically with decoupled control law both for the grid side converter (GSC) and rotor side converter (RSC). A duel overcurrent protection is implemented for the rotor windings and DC-link for damping of excess energy from the rotor shaft during grid disturbances [6]. The proposed DFIG WT model has been implemented in PSCAD/EMTDC simulation tool. The validation of investigated model is further done by the simulation results of different case studies.

II. MODELING OF DFIG BASED WIND TURBINE SYSTEM

A. Components of DFIG Wind Turbine

In a DFIG based wind turbine, the turbine shaft is connected with the generator shaft through a gearbox. The stator windings are connected to the grid via coupling transformer, while the rotor windings are connected with the grid through a back-to-back voltage source converter (VSC) system as depicted in Fig. 1. The DFIG feeds power to the grid from both its stator (approx. 2/3 of P_n) and rotor (approx. 1/3 of P_n) windings.

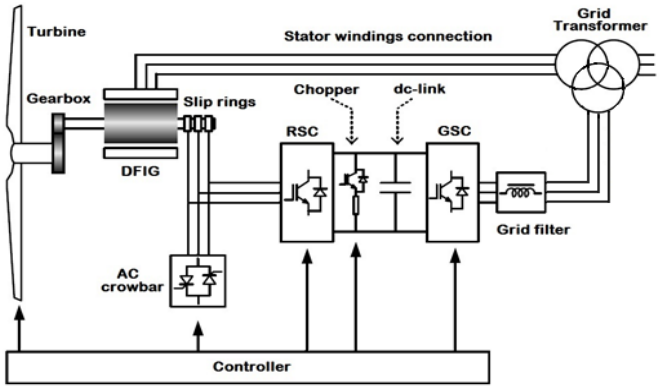

Fig. 1. Components of a DFIG WT system

The purpose of the RSC is to control the rotor currents in such a way that; the desired torque is developed at the shaft of the DFIG. The GSC regulates the dc-link voltage across the DC-link capacitor by exchanging active power with the grid. It can also control reactive power exchanged between the GSC and the grid. Here, both the VSCs operate in 4 quadrants for bidirectional power flow between rotor windings and the grid network [7].

B. Mathematical Model of DFIG

The DFIG model presented in this paper is based on the inverse gamma model (Γ-model). The stator dynamics of the DFIG is ignored in this Γ-model representation. The rotor dynamics of a DFIG are predominantly controlled by the RSC & GSC for stable operation. Therefore, for transient stability analysis, the Γ-model representation of induction generator as shown in Fig. 2 is considerably reasonable choice for mathematical modeling of DFIG WT system [3].

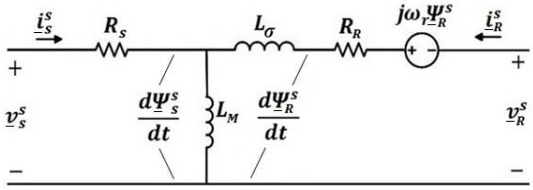

Fig. 2. Γ-model representation of IG in stator coordinates

This model is described by the following differential equations in synchronous coordinates with the help Clark's and Perk's transformation.

$$\underline{v_s} = R_s\underline{i_s} + \frac{d\underline{\Psi_s}}{dt} + j\omega_k\underline{\Psi_s} \tag{1}$$

$$\underline{v_R} = R_R\underline{i_R} + \frac{d\underline{\Psi_R}}{dt} + j\omega_{slip}\underline{\Psi_R} \tag{2}$$

Where v, i and Ψ denote the voltage, current and flux quantity respectively and ω_r is the frequency of the rotor. The subscripts s and R refer to the quantities of the stator and rotor respectively. Moreover, the superscript s is used to identify space vector that refer to the stator coordinate system. Finally, the vectors with no superscript represent quantities refer to synchronous coordinate system. The term ω_k and ω_{slip} represent the synchronous and slip frequencies respectively. The stator flux, rotor flux and electromechanical torque are given by (3), (4) & (5) respectively.

$$\Psi_s = L_M(i_s + i_R) \tag{3}$$

$$\Psi_R = (L_M + L_\sigma)i_R + L_M i_s = \Psi_s + L_\sigma i_R \tag{4}$$

$$T_e = \frac{3}{2}n_p \mathrm{Im}[\Psi_s {i_R}^*] \tag{5}$$

$$\frac{J}{n_p}\frac{d\omega_r}{dt} = T_e - T_m \tag{6}$$

Where L_M is the magnetizing reactance, L_σ is the leakage inductance. Finally, the mechanical dynamics of the induction generator can be described by (6) where, J is the inertia of single mass WT model and T_m is the mechanical torque.

The conversion of different parameters of DFIG from the classical T-model into Γ-model is done as per the following relations as given in [2] where, the "r" in subscript represents the rotor quantities in classical T-model.

$$v_R = \gamma v_r \qquad i_R = \frac{i_r}{\gamma} \qquad \Psi_R = \gamma\Psi_r \qquad \gamma = \frac{L_{s\lambda} + L_m}{L_m}$$

$$R_R = \gamma^2 R_r \qquad L_\sigma = \gamma L_{s\lambda} + \gamma^2 L_{r\lambda} \qquad L_M = \gamma L_m$$

C. Series Filter Modeling for GSC

The GSC is connected to the grid through AC filter in order to reduce current transient. A *L*-filter or *LCL*-filter is mainly used as grid filter for voltage source converter [2]. For simplicity, *L*-filter is used in this DFIG WT model. The series filter impedance ($Z_f = R_f + jX_f$) has been chosen as 10% of base impedance of GSC. Filter losses has been evaluated as 10% of the filter reactance. By evaluating with numerical values, the GSC series filter is found as follows:

$$L_f = 0.0869\ mH \qquad R_f = 3.279 m\Omega$$

III. Control of DFIG Based Wind Turbine System

The control algorithms of the RSC are derived in the stator flux oriented d-q coordinate system. For coordinate transformation of RSC quantities, the phase angle of the stator flux is estimated in an open loop manner by measuring grid voltage and the stator current instantaneously.

$$\underline{\Psi_s^s} = \int (\underline{v_s^s} - R_s\underline{i_s^s})dt = |\Psi_s^s| \angle\mu \tag{7}$$

The output of an integrator (as estimated stator flux) is further passed through a band pass band filter with low cut-off frequency for avoiding the DC offsets, as suggested in [8].

To perform the coordinate transformation, the phase angle of the voltage vector must be known which can be estimated through a PLL in practical applications [9]. Since the GSC control system is aligned with the grid voltage vector, here the PLL is tracking the grid voltage E_g applied to the GSC in the secondary of the coupling transformer yielding $E_g = E_{gd}$ and $E_{gq} = 0$ in steady state condition. The law governing the PLL is considered as the one proposed in [10] where the controller gains are defined as

Proportional gain, $K_{p,PLL} = 2\,\alpha_{PLL}$

Integrator gain, $K_{i,PLL} = {\alpha_{PLL}}^2$

The bandwidth of the PLL for GSC is selected to be low as $\alpha_{PLL} = 34\ rad/s$. Thus the higher order transient of the grid voltage is rejected when the PLL operates with a reduced bandwidth [11]. Also the stability of the WT system improves with low bandwidth of PLL during grid disturbances [12].

A. Control of Rotor Side Controller

To utilize the advantage of variable speed operation of a DFIG based wind turbine, the tracking of optimum torque-speed curve is essential [13]. The speed of the rotor can be adjusted to a desired value by controlling the torque. The optimum power point is tracked by following a predefined torque-speed characteristic of the wind turbine. The turbine output power reference is varied according to the measured

rotor speed. In this DFIG WT model, the following relation between optimum power (P_{opt}) and turbine speed (ω_t) is used.

$$P_{opt} = K_{opt}{\omega_t}^3$$

Where, $K_{opt} = \frac{1}{2}\rho A C_{p_{opt}} \left(\frac{R}{\lambda_{\text{opt}}}\right)^3$ is constant. Also the terms $\rho, A, C_{p_{opt}}$ and λ_{opt} represent air density, swept area, power coefficient and optimum tip speed ratio of the turbine respectively.

Current Control

In order to derive the rotor current control law, (2) can be re-written in terms of state variable i_R and the input signal v_R by substituting the value of (4) into (2) as follows:

$$\underline{v_R} = (R_R + R_s + j\omega_{slip}L_\sigma)\,\underline{i_R} + L_\sigma \frac{d\underline{i_R}}{dt} + \underline{E} \tag{8}$$

Here, E is the back EMF and the term $j\omega_{slip}L_\sigma \underline{i_R}$ is the cross-coupling term. Assuming perfect parameter estimation and cancellation of back EMF the rotor current dynamics formed by introducing active damping (R_a) and cross-coupling term as follows:

$$\underline{v_R}' = (R_R + R_s + R_a)\underline{i_R} + L_\sigma \frac{d\underline{i_R}}{dt} \tag{9}$$

Therefore, applying internal model control (IMC) method [11], (9) yields a PI controller of gain parameters as follows:

Proportional gain, $K_{p,P} = \alpha_{rsc} L_\sigma$

Integrator gain, $K_{i,P} = \alpha_{rsc}(R_R + R_s + R_a)$

The bandwidth of the current controller is selected to be $\alpha_{rsc} = 3000\, rad/s$. Finally, the rotor current law can be rewritten as below and the controller diagram is shown in Fig. 3.

$$\underline{v_R} = \left(K_{p,P} + \frac{K_{i,P}}{s}\right)(\underline{i_R}^{ref} - \underline{i_R}) + \left(j\omega_{slip}L_\sigma - R_a\right)\underline{i_R} + \underline{E} \tag{10}$$

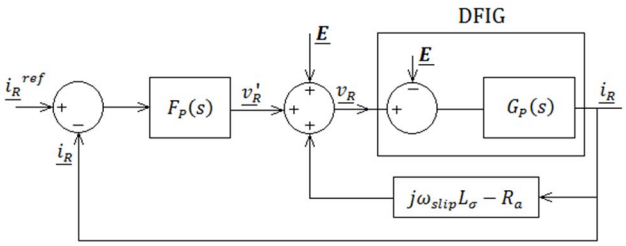

Fig. 3. Diagram of RSC current controller.

Power and Torque Control

In a stator flux coordinated system, $v_{sd} = 0$ assuming the stator resistance is negligible. The active and reactive power of the stator of a DFIG can be expressed in terms of rotor current quantities of synchronously rotating reference frame as follow:

$$P_s = -\frac{3}{2}(v_{sq} i_{Rq}) \tag{11}$$

$$Q_s = \frac{3}{2} v_{sq}(i_M - i_{Rd}) \tag{12}$$

It can be seen that, P_s and Q_s can be controlled independently by regulating the rotor current components, i_{Rq} and i_{Rd} respectively. This model control the torque in an open loop manner by following the electro-dynamical torque T_e expression as follows:

$$T_e = \frac{3}{2} n_p \text{Im}[\underline{\Psi_s}\,\underline{i_R}^*] \approx -3\underline{\Psi_s} i_{Rq} \tag{13}$$

The pole-pair of this DFIG machine under consideration in the PSCAD simulation model is $n_p = 2$ [14].

Speed Control

Based on the mechanical dynamics of the induction machine, a proportional controller is used where the gain parameter is as follows:

Proportional gain, $K_{p,S} = \frac{J\alpha_S}{n_p}$

$$T_e^{ref} = K_{P,S}(\omega_r^{ref} - \omega_r) \tag{14}$$

In this model, the bandwidth of the speed controller is selected as, $\alpha_S = 150\, rad/s$.

B. Control of Grid Side Controller

The GSC control scheme consists of two cascaded control loops. The inner current control loop regulates independently the d-axis and q-axis of the filter current, i_{fd} and i_{fq} respectively. The outer loop regulates the dc-link voltage and the reactive power exchange between the grid and GSC.

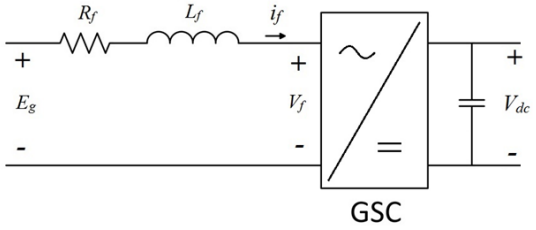

Fig. 4. GSC with L-filter

Fig. 4 shows the simplified model of GSC. The dynamics of the grid filter in synchronously rotating reference frame can be expressed as (15) where ω_g is angular frequency of the grid voltage and $L_f\omega_g \underline{i_f}$ is the cross coupling term.

$$\underline{v_f} = -(R_f \underline{i_f} + L_f \frac{d\underline{i_f}}{dt}) - jL_f\omega_g \underline{i_f} + \underline{E_g} \tag{15}$$

Current Controller

Applying IMC method on (15) yields a PI controller as follows:

$$\underline{v_f} = -\left(K_{f,P} + \frac{K_{f,P}}{s}\right)(\underline{i_f}^{ref} - \underline{i_f}) - j\omega_g L_f \underline{i_f} + \underline{E_g} \quad (16)$$

Where, the GSC current controller gains are defined as

Proportional gain, $K_{p,g} = \alpha_{gsc} L_f$

Integral gain, $K_{i,g} = \alpha_{gsc} R_f$

Bandwidth of GSC current controller,

$$\alpha_{gsc} = 3000\ rad/s$$

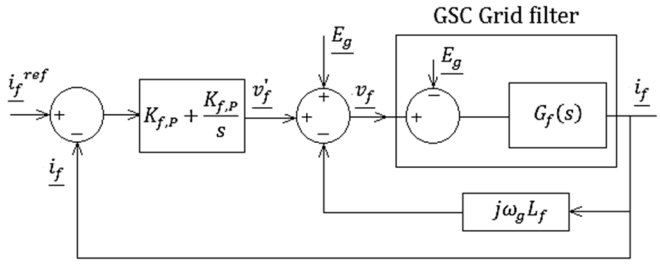

Fig. 5. Diagram of GSC filter current controller.

DC-link Controller

In the simplified DC-link model as shown in Fig. 6, the amount of the power that flows through the DC-link capacitor depends on the power delivered to the DC-link from GSC, P_{gsc} and the power delivered to the rotor of the DFIG, P_r.

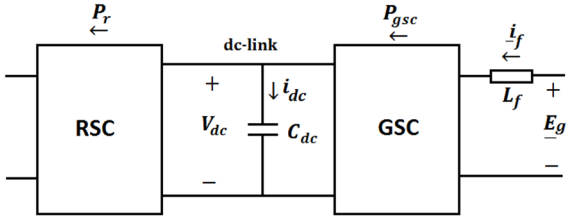

Fig. 6. Simplified DC-link model

Under the assumption that, the GSC is lossless and the DC-link capacitor is constant in time, the power flowing in the DC-link P_{dc} must be equal to the energy stored in the DC-link capacitor, yielding

$$P_{gsc}(t) - P_r(t) = P_{dc}(t) = \frac{dE_{dc}(t)}{dt}$$

$$= \frac{1}{2} C_{dc} \frac{d(V_{dc})^2}{dt} \quad (17)$$

To derive the control law, (17) can be linearized as suggested in [15]

$$\frac{1}{2} C_{dc} V_{dc,0} \frac{d\Delta V_{dc}}{dt} = P_{dc} = \Delta P_{gsc} - \Delta P_r \quad (18)$$

Observed that, the closed loop dynamics depends on the operating point of the dc-link voltage, $V_{dc,0}$. This inconvenience can be avoided by using the square of the dc-link voltage $(V_{dc})^2 = W$ in the control law as suggested in [15]. However, applying IMC the (17) yields a proportional controller with gain $K_{p,dc} = \frac{\alpha_{dc} C_{dc}}{2}$. Therefore, the complete control law is given as

$$P_{gsc}^{ref} = \left(K_{p,dc} + \frac{K_{i,dc}}{s}\right)(W^{ref} - W) + P_r \quad (19)$$

Observed from (19) that, the active power delivered to the rotor (P_r) is included in control law as a feed forward term. Finally, using amplitude invariant transformation, the d-axis grid filter current reference i_{fd}^{ref} can be derived as

$$i_{fd}^{ref} = \frac{2}{3} \frac{P_{gsc}^{ref}}{E_{gd}} \quad (20)$$

The bandwidth of the outer controller should be 5 to 10 times smaller than the inner controller [4]. Here, the bandwidth of the DC-link controller is selected to be $\alpha_{dc} = 300\ rad/s$.

IV. DFIG WT Protection System

In spite of having a number of advantages, a major drawback of DFIG based wind turbine system is their lower LVRT capability. Any voltage dip at grid induces a serious over-voltage as well as over-current in the rotor windings. Moreover, a major part of this over-current will flow through the dc-link capacitor which results an over-voltage in the DC-link [16].

In this DFIG model, an AC crowbar system is directly connected to the rotor windings to prevent the rotor transient over-current to pass through the rotor side converter valves. The selection of the crowbar resistance is made according to (21) as suggested in [16].

$$R_{AC-cb} < \frac{V_{dc,nominal}}{\sqrt{6} I_{rsc,max}} \quad (21)$$

Where, $V_{dc,nominal}$ is the nominal dc-link voltage and $I_{\text{rsc,max}}$ is the maximum allowable rotor current. Normally, the IGBTs in the converter can handle twice as much as the nominal current of the converter for 1 ms. For this reason, the typical set point for the maximum allowable rotor current is considered as 1.8 times the nominal rotor current as suggested in [15]. Therefore, the AC crowbar resistance can be found as

$$R_{AC-cb} < \frac{0.94\ kV}{\sqrt{6}\ (1.8 * 0.84\ kA)} < 0.254\ \Omega$$

In this model the AC crowbar resistance is set to be $R_{AC-cb} = 0.25\ \Omega$.

For the dc-link over-voltage protection, an IGBT controlled DC crowbar is placed across the dc-link buses. When the DC-link bus voltage reaches the maximum allowable voltage set point, the IGBT will act and thereby, the excess energy of the DC-link capacitor will be discharged through the DC crowbar resistance, $R_{dc-link}$ until the DC-link voltage become lower than the maximum set point. In this DFIG based WT model, the maximum dc-link voltage is set at 1.05 pu and the dc-link chopper resistance is chosen as $R_{dc-link} = 1\Omega$. This DC crowbar system will improve the voltage ride through capability of the DFIG WT system which compromises its high installation cost [17].

V. Simulation Results

A. Performance of DC-link Controller

One of the important analysis on the stability of a DFIG WT control system is the performance of the DC-link controller. The DC-link voltage must be kept constant within a predefined limit to prevent the rotor shaft from over-speed caused by undamped excess energy in case of any grid disturbance. Thus the dynamics of the DC-link controller must be fast enough to ensure that the actual DC-link voltage follows the reference in all operating conditions. The performance of the DC-link controller used in this model is analyzed by two different step response of the DC-link voltage reference (a negative step at 3s and a positive step at 3.7s) as shown in Fig. 7.

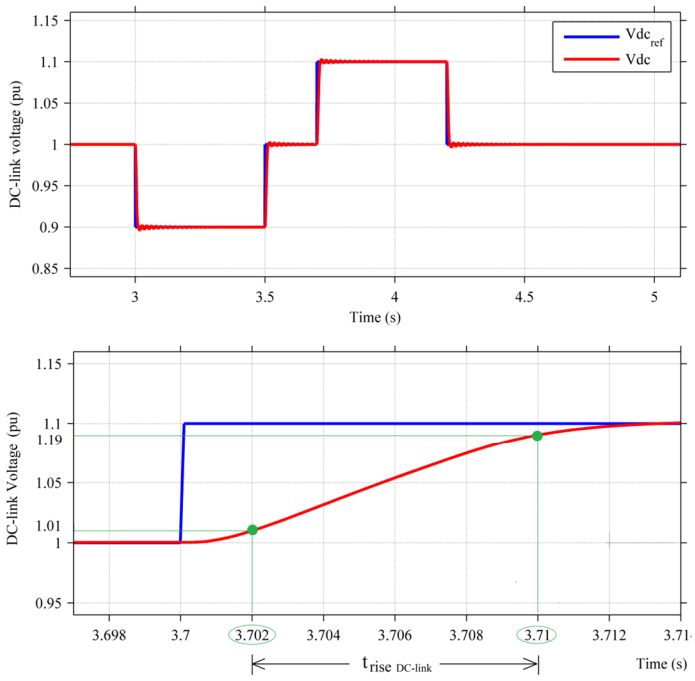

Fig. 7. (a) Performance of the dc-link voltage controller against step variations of the DC-link voltage reference; (b) Rise time of DC-link voltage.

It can be observed from the Fig. 7(a) that, there are small oscillations in the DC-link voltage upon step changes. Although the DC-link model is a first order system, the addition of the small integrator gain in the controller makes the close loop system as a second order system. Moreover, there is a small time delay (1 ms) between the measured GSC power and the GSC power reference ($P_{gsc}{}^{ref}$) imposed by the controller. This is an important factor that causes a very small overshoot and oscillation in the DC-link voltage. However, the DC-link controller is able to damp the oscillation within 150-200 ms, so that, the dynamic performance of the DC-link controller can be considered suitable for the investigated DFIG WT model. Moreover, Fig. 8(b) shows that, the rise time of the actual DC-link voltage is 8 ms; where, the theoretical rise time of the modeled DC-link voltage controller is 7.3 ms $\left(\frac{\ln 9}{\alpha_{dc}}\right)$ according to the selected DC-link controller bandwidth.

B. Verification of DFIG WT Model

Case Study 1

Depending on the mode of operation (i.e. Sub-synchronous or Super-synchronous), the power flow direction between the rotor windings and the grid changes as shown in Fig. 8. Neglecting the losses in the generator and power converter, the relation between the stator power (P_s) and rotor power (P_r) can be seen by [18]

$$P_r = -sP_s \tag{22}$$

where, s is the slip of the DFIG defined as $s = \frac{\omega_k - \omega_r}{\omega_k}$

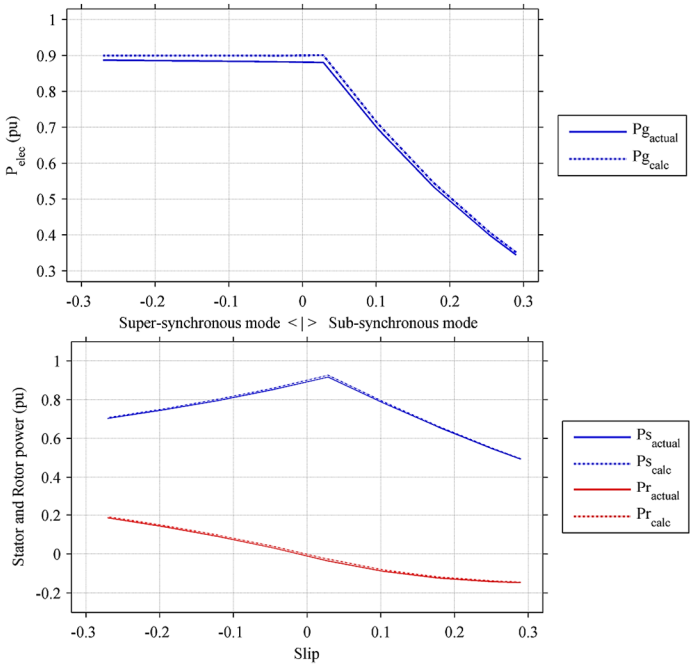

Fig. 8. Steady state power flow of DFIG at different slip: (a) total generated power; (b) stator and rotor power.

Fig. 8 shows the steady state power flow performance with respect to different slip conditions where the incident wind velocities are taken as constant. It can be seen from the plot (a) that, the actual generated power (Pg_{actual}) from the wind turbine at different slip is almost identical to the calculated power (Pg_{calc}). Similarly in plot (b), the actual stator and the rotor power follows the calculated stator and rotor power respectively at different operating conditions. Moreover, the polarity of rotor power changes exactly at slip zero, which further validates the implemented DFIG WT model.

Case Study 2

The dynamic performance of the rotor current of the DFIG model is illustrated in Fig. 9. The DFIG WT initially operates with a rotor speed at $\omega_r = 0.9\ pu$. From $t = 4\ sec$ the speed reference is gradually increased from 0.9 pu to 1.1 pu in 6 seconds which means, the operation mode of the DFIG switches from sub-synchronous mode into super-synchronous mode. During this ramp up time, the wind speed is assumed to be constant.

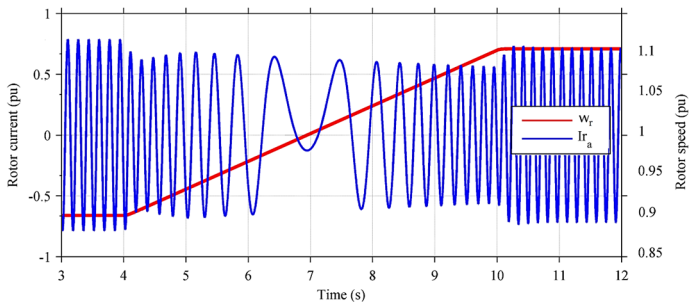

Fig. 9. DFIG rotor acceleration through synchronous speed.

A smooth transition of the rotor current is observed at $t = 6.9\ sec$ from sub-synchronous to super-synchronous mode without being distorted by higher order harmonic which signifies the effectiveness of the RSC controller used in this DFIG WT model.

Case Study 3

In this case study, a symmetrical voltage dip is emulated during which the remaining voltage at the point of common coupling (PCC) is controlled at 0.2 pu. for a period of 200ms as depicted in Fig. 10(a). Before this event, the wind turbine is generating nominal active power of 0.9 pu with unity power factor and with nominal slip equal to 2.7%.

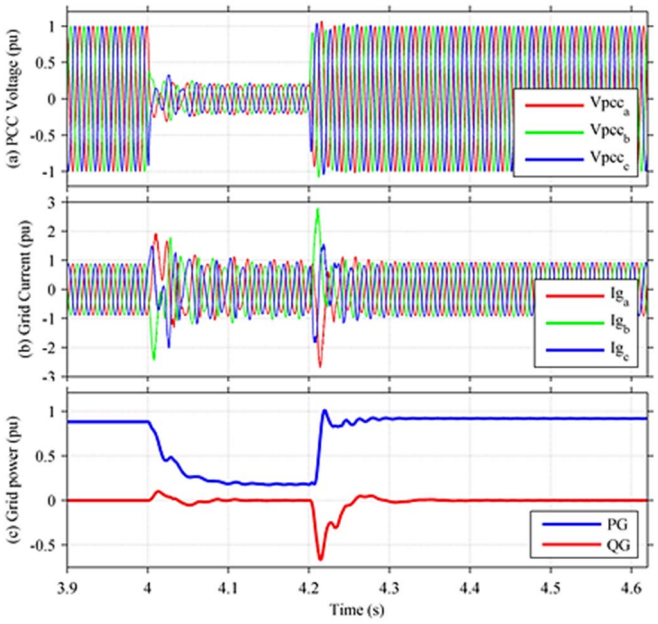

Fig. 10. Responses during symmetrical voltage dips: (a): three-phase terminal voltages; (b): three-phase current (I_g); (c): active and reactive power

As shown in Fig. 10(b), the maximum fault current from the wind turbine reaches 2.9 pu during the recovery of the grid voltage whereas a current peak of 2.4 pu is produced during the first 30ms of the voltage dip. Fig. 10(c) shows that, after the voltage recovery, the active power rises towards its pre-fault value due to the increasing voltage and current transient. As a result the DFIG WT reaches steady state within two electrical periods after voltage recovery. Finally, the reactive power is controlled in zero at steady state.

VI. Conclusion

This paper presents a complete model of DFIG WT with all control systems. The mathematical model is developed in PSCAD/EMTDC simulations. The dynamic response of simulated model with decoupled control of RSC and GSC are found consistent with the mathematical model through different case studies. This model can be used for investigating the transient stability and voltage ride through capability of DFIG based WT systems.

***Abstract*— CdTe is a very potential absorber material for thin film solar cell application. In this work CdTe thin films (TF) were deposited on CdS thin films by close-spaced sublimation (CSS) technique at different source and substrate temperature in inert gas condition. To bring out the optimum temperature set for CSS deposited CdTe films, several experiments were done. The process pressure of the chamber during deposition was maintained at 1.5 Torr in a dynamic condition. The effects of deposition temperature on the electrical properties of the as-deposited CdTe films were investigated by Hall Effect measurement. The films were deposited at 610 ˚C, 630 ˚C, 650 ˚C and 670 ˚C source temperatures. The first three films showed p-type conductivity while n-type conductivity appeared in the film deposited at 670 ˚C. The hole concentration of the as-grown p-type CdTe films followed an upward trend with the increase of source temperature and it reached a peak value at 650 ˚C. The highest hole mobility was observed for the lowest source temperature. However, the resistivity of the CdTe films was found increasing with the increase of source temperature. Thus, the CdTe thin film deposited at 650 ˚C showed better electrical properties for solar cell applications.**

Keywords—CdTe thin film, Close-spaced sublimation, Electrical properties, Hall Effect measurement, Solar cells.

Introduction

CdTe is considered as a leading polycrystalline materials for the fabrication of highly efficient thin film (TF) hetero-junction solar photo-voltaic (PV) cells. Some unique physical properties make it an ideal p-type absorber material for solar PV cells. These properties include a direct band gap of about 1.45 eV which is optimum for the absorption of solar irradiation, an absorption coefficient which can be higher than 5×10^5 cm^{-1} at incident wavelengths of about 700 nm and the highest lattice parameter in the II-VI semiconductor group. Besides these, its formation energy is negative and the lowest among the members of this group. The CdS/CdTe based thin-film solar PV cells have already attained the efficiency over 22% in research level and over 18% in module level [1-2]. There are several techniques to deposit CdTe thin-films on CdS layer in which small-area laboratory solar cell demonstrate efficiency over 10% [3]. The most remarkable ones are CSS, electro-deposition, vacuum evaporation, sputtering, Vapor Transport Deposition (VTD), Metal Organic Chemical Vapor Deposition (MOCVD), Molecular Beam Epitaxy (MBE), and screen printing. All these techniques allow the deposition of high-quality thin films of CdTe which is polycrystalline in nature. However, the most efficient CdTe TF solar cells have been found with CdTe absorber layers deposited using CSS technique till to date [4]. Moreover, this technique is attractive among the researchers because of its high deposition rate, the simplicity of operation, and lower vacuum level during deposition and easiness of fabricating large volume commercial modules [5-6]. The most vital deposition parameters of CSS equipment are included; the temperature of source and substrate, the chamber pressure, the deposition time and the deposition atmosphere [7-11]. The photovoltaic conversion efficiency depends on the microstructure, optical and electrical properties of the as-grown CdTe thin film absorber layers which can be regulated by the deposition parameters. Researchers around the world are trying to find out the relationship between these properties and the deposition parameters [12]. The built-in bias voltage at equilibrium open circuit voltage V_{bi} is related to the carrier concentration of absorber and window material according to (1) [13].

$$V_{bi} = \frac{k\,T}{q} \ln\left(\frac{N_d N_a}{n_i^2}\right) \tag{1}$$

Where k is Boltzmann constant, N_a, N_d, and n_i are acceptor, donor and intrinsic carrier concentration per cm^3 of absorber and window layer, q is the charge of electron and T is the temperature. Larger built-in potential is desirable for separating light generated electron-hole pair in the absorber material. The short circuit current density Jsc is related to the parasitic series (R_s) and shunt resistance (R_{sh}) according to (2) [13].

$$J_{sc} = J_o\left[e^{\frac{(q(V-R_sJ_{sc})}{AkT}} - 1\right] - J_L + \frac{(V - R_sJ_{sc})}{R_{sh}} \tag{2}$$

Where A is the diode quality factor and J_o is the saturation current density. In this work, the CdTe thin films were deposited on 100 nm thick CdS thin films for four different source and substrate temperature. The temperature difference (ΔT) between source and substrate of the CSS equipment was kept at 30 ^{0}C. The source temperature was gradually increased from 610 ^{0}C to 670 ^{0}C in a steps of 20 ^{0}C. The dependence of several electrical properties such as carrier concentration, resistivity and carrier mobility of the as-deposited CdTe thin films were investigated by Hall Effect measuring system.

I. Experiment

The 3 cm × 3 cm borosilicate glass substrate was used to deposit CdTe TF by CSS techniques due to its better optical transmittance in the visible wavelength and higher strain point than soda lime glass [15]. The substrates were subject to cleaned by standard cleaning procedure. The substrates were scratched by the pen cutter in one side for marking and then scrubbed manually for 30 s each side with a nylon brush in soapy water. After that, the substrates were rinsed with warm deionized water and then cleaned ultrasonically by methanol, acetone, methanol and deionized water respectively at a temperature 50 ^{0}C for 15 minutes each. The clean substrates were dried with N_2 gas and then air anneal in a hot plate at 100 ^{0}C for 5 minutes. Finally, four cleaned substrates were mounted to the substrate holder in an RF sputtering machine. The distance between target and substrate was kept 7 cm. A 100 nm thick CdS film was deposited on each clean substrate by RF sputtering under 3.9 mTorr working pressure for 30 minutes using 99.99% pure CdS target of 2-inch diameter. During deposition Ar gas flow was maintained to 16 sccm through MFC controller. The RF power of the plasma gun was kept to 30 W while the substrate temperature was at 100 °C. The as-deposited CdS film shown in Fig. 1.

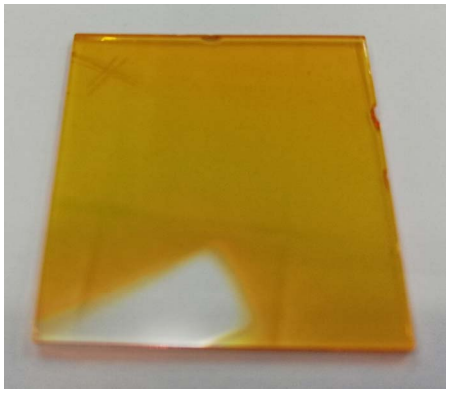

Fig. 1 RF sputtered as-deposited CdS films

The thickness of the CdS film was measured by the Quartz Crystal-deposition Monitor (QCM). The deposited CdS films were stored in a vacuum desiccator for avoiding the detrimental effects on the film-quality. The schematic diagram of traditional CSS equipment is shown in Fig. 2. The CSS equipment deposits CdTe film on one CdS film at a time. The 4N analytical grade CdTe powder was used as source material.

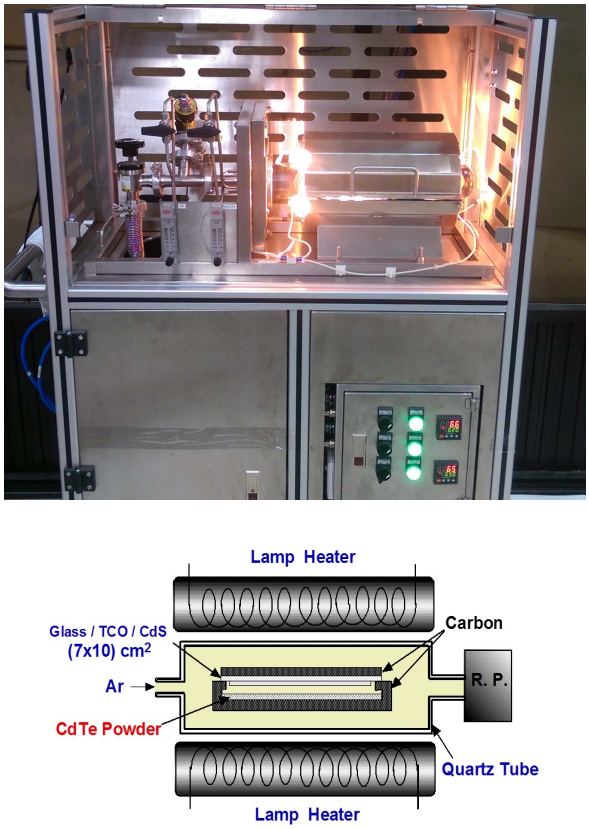

Fig. 2 CSS equipment with schematic diagram of chamber

The CdTe powder was poured into a graphite susceptor having 2.85 cm × 2.85 cm width, and 0.6 mm depth. The source powder was then compacted by a 2 cm× 5 cm glass slider. Finally, the CdTe powder was sintered to form a hard CdTe compound at 700 ^{0}C temperature for 30 minutes in Ar ambient. After that, the CdS film faced down towards the CdTe source as shown in Fig. 3.

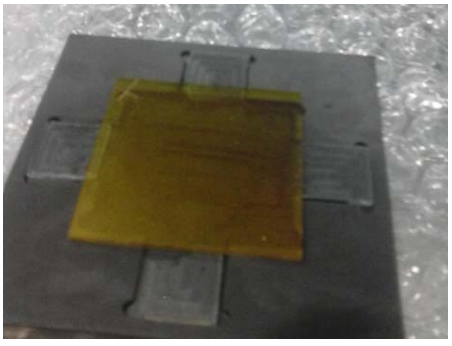

Fig. 3. CdS Films facing towards the CdTe Solid.

The important process parameters for depositing high-quality CdTe TF include the temperature of the source (T_{sou}) and substrate (T_{sub}), the spacing between source and

substrate, process pressure and process gas (Ar, He, or Mix) [3, 5]. The spacing between source and substrate was fixed at 2 mm and the process temperature was monitored by inserting thermocouple into the graphite susceptor and controlled by a PID controller. Two 2 kW tungsten halogen lamps were used, one at the bottom and the other at the top of the quartz tube for heating the source and substrate as illustrated in Fig. 2. The chamber was kept at a vacuum of 10 mTorr by a rough pump before deposition and then purged with highly pure N_2 gas. After that Ar gas was applied to the chamber. During the deposition, the chamber pressure was monitored by Instrutech pressure gauge and maintained at 1.5 Torr by regulating a throttle valve connected between the rough pump and the chamber. The CdTe films were deposited at four different source temperatures starting at 610 °C and then increased to 670 ^{0}C in three steps of 20°C equal increment while keeping the difference between the source and substrate temperature constant at 30 °C. The deposition time of each films were maintained to10 minutes. The as-deposited CdTe TF is shown in Fig. 4.

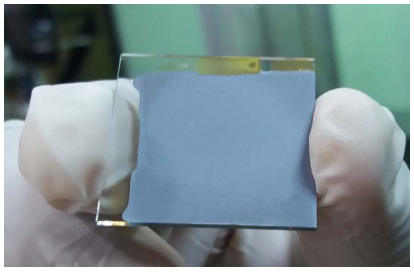

Fig. 4 As-deposited CdTe films on CdS films

II. Results and Discussion

The three major electrical properties including carrier concentration, mobility and resistivity of the as-deposited CdTe thin films were observed at room temperature by Hall/resistivity measurements. The ECOPIA Hall effect measurement system (HMS-3000) which is integrated with a resistivity measurement tool was used for this purpose. The system uses the van der Pauw method which is a four-probe method for the Hall measurements. During the measurements, a constant magnetic field was produced by using a pair of permanent magnets and then applied orthogonally to the upper surface of the films. Meanwhile, a DC (direct current) was made to pass through the thin film samples by using one of the two diagonal pairs of gold electrodes, electrically connected to a constant dc current source. The induced hall voltage was detected by the remaining electrode pair. The magnitude of the applied magnetic field was constant at 0.51 T. The type (p or n) of the CdTe films was denoted by the system using a positive (+) or negative (-) sign preceding the numerical value of the carrier concentration. The details results are discussed in the following subsections.

A. Effect of Temperature on Carrier Concentration

The calculation of the carrier concentration and mobility was done by the system itself using the magnitude of the induced hall voltage. Fig. 5 shows the effects of source temperature on the majority carrier concentration in the CdTe films. It is evident from Fig. 5 that the carrier concentration increases with the increase in source temperature. The values of carrier concentration were found 6.38×10^{11} cm^{-3}, 4.2×10^{12} cm^{-3}, 7.7×10^{12} cm^{-3}, and -6.78×10^{12} cm^{-3} for the samples deposited at source temperatures of 610 ^{0}C, 630 ^{0}C, 650 ^{0}C and 670 ^{0}C respectively. The highest carrier concentration was found in the sample deposited at 650 ^{0}C source temperature. As the photovoltaic conversion efficiency is directly related to the carrier concentration, the CdTe films deposited at this source temperature are expected to yield the more efficient solar cells than the films deposited at other source temperature which is very consistent with the results reported by the other researchers [4-6].

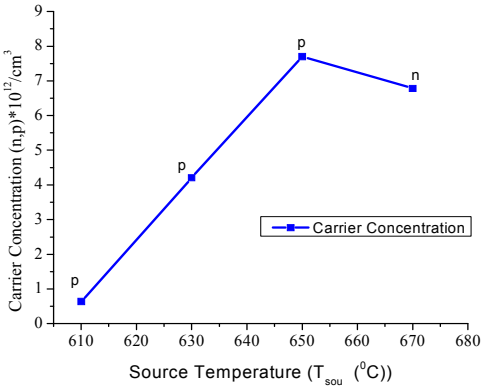

Fig. 5 Effect of temperature on CdTe TF carrier concentration

Another interesting observation is that, the CdTe films deposited at source temperatures higher than 650 ^{0}C become n-type semiconductor which is not expected in case of CdTe thin film solar cells because the CdTe is usually used as the p-type absorber layer. These might be happened for source temperature higher than 650 ^{0}C, where the sublimation rate of the cadmium atoms on the CdS layer surpasses that of tellurium atom. As a result, the percentage of cadmium becomes higher than the tellurium in the CdTe films and thus the films become n-type.

B. Effect of Temperature on Carrier Mobility

The variation of majority carrier mobility with the source temperature is shown in Fig. 6.

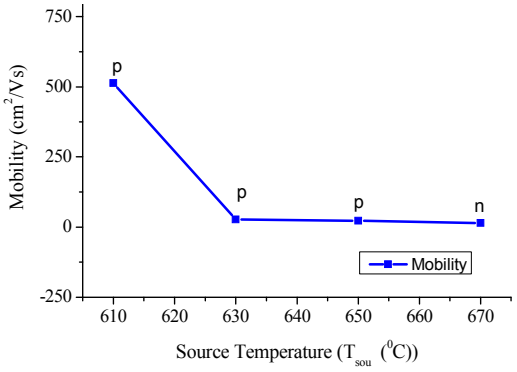

Fig. 6 Effect of temperature on CdTe TF carrier mobility.

In the figure it is observed that, hole mobility is highest (512 cm^2/Vs) in the sample deposited at 610 ^{0}C source temperature. As the source temperature increases from 610 ^{0}C to 630 ^{0}C, the hole mobility decreases significantly from

512 cm^2/Vs to 25 cm^2/Vs. After that, the rate of decrease in mobility become not significant. For the source temperature of 630 ^{0}C and 670 ^{0}C, the mobility was found to be 22 cm^2/Vs (hole) and 15 cm^2/Vs (electron) respectively. The decrease in carrier mobility with the increase in source temperature is agreeable with the theory. As the source temperature increases, the carrier concentration also increases. As a result the mean free path of the carriers decreases and the total number of collisions per carrier to travel a certain distance increases consequently decreasing the carrier mobility.

C. Effect of Temperature on Resistivity

The Fig. 7 demonstrates the change in film resistivity with the increase in source temperature is shown. It is clear from Fig. 7 that the resistivity shown an increasing trend with the increase in source temperature.

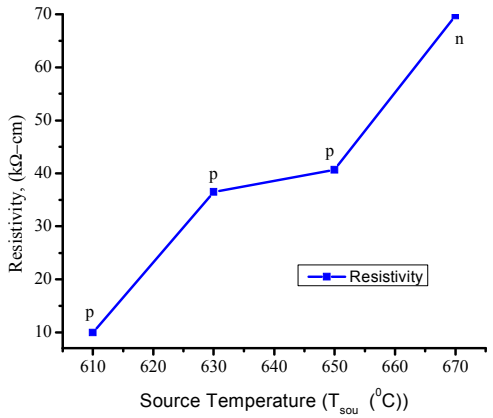

Fig. 7 Effect of temperature on CdTe TF resistivity

The resistivity was found 9.96 kΩ-cm, 38.6 kΩ-cm, 40.7 kΩ-cm and 70 kΩ-cm for the samples deposited at source temperature of 610 ^{0}C, 630 ^{0}C, 650 ^{0}C and 670 ^{0}C respectively. Among the p-type CdTe films, the highest resistivity was found in the sample for 650 ^{0}C source temperature. The resistivity of as-deposited CdTe films were lower than the results reported by the other researcher [15-18]. The n-type CdTe thin film offers the highest resistivity among the four CdTe TF samples. This may be because of the lowest mobility found in n-type CdTe as-deposited films.

In general, a higher carrier concentration, lower resistivity and higher mobility are desirable for the absorber layer to increase open-circuit voltage V_{oc}, fill factor FF and short-circuit current density J_{sc} of the solar cell. It is very difficult to achieve all these suitable properties in a single film. Therefore, in practice rigorous optimization is recommended for this purpose. Considering all the electrical properties finally it is concluded that, the CdTe film deposited at 650 °C source temperature is suitable as the absorber layer in solar cell applications.

III. CONCLUSION

The performance parameters of CdTe solar cell are directly depends on the micro-structural, electrical and optical properties of different functional layers. In CSS technique the direct phase transition occurs between the CdTe solid to gas state congruently. The main focus of the work was to investigate the temperature dependence of electrical properties of as grown CdTe TF. Both the p-type and n-type conductivity of CdTe TF were found for different source and substrate temperatures. The carrier mobility of the CdTe TF dramatically decreases for the source temperature increasing from 610 °C to 630 °C, whereas the resistivity of the CdTe TF increase with source temperature. The effects of the source and substrate temperature on the electrical properties of CdTe films were found consistent with the other related published works. The electrical properties of the CdTe TF at 650 °C source temperature were found to be better than the counterparts deposited in dynamic condition.

***Abstract*—In recent years Organic Solar Cells have become a prominent topic of research to achieve an optimum efficiency at low cost. By using the GPVDM software on this paper, we have analyzed the effect on power conversion efficiency, changing simultaneously both the polymers and blending layer thickness of P3HT:PCBM based solar cell. Our main goal is to find which layer change keeps the power conversion efficiency output better. After comparing them, the result shows that setting the active layer (P3HT:PCBM) in an optimum fixed value and varying the polymer layer (PEDOT:PSS) gives a better output of PCE. In our paper, from the data in both cases, The highest efficiency is 4.50 percent where P_3HT:PCBM layer thickness is 2.2×10^{-7} m and PEDOT:PSS layer thickness is 1×10^{-7} m.**

***Keywords*—P3HT:PCBM, PEDOT:PSS, PCE, Organic solar cell, active layer, blending layer, polymer layer.**

I. INTRODUCTION

Organic bulk heterojunction (BHJ) solar cells will have a very large impact on renewable energy in near future. Being flexible and semitransparent, organic solar cells are different from the inorganic solar cells[1]. In organic solar cells, organic polymers are used to absorb the light and for transporting the charge in order to produce electricity. They can cover larger range of surfaces than inorganic solar cells and the manufacturing costs are significantly lower than the conventional inorganic cells[2],[3]. They also can be processed easily than inorganic solar cells [7]. It is called bulk heterojunction solar cells as electron acceptor and donor materials are blended in a disordered orientation which limits its Power Conversion Efficiency (PCE)[4],[5].

In order to improve the performance and power conversion efficiency, we have changed the layer thickness and observed the characteristics curve which we have generated using General-Purpose Photovoltaic Device Model (GPVDM)[6]. It is a free general-purpose software (a potential device simulator) for photovoltaics where the model has been tested in steady state time domain (usfs time scales and fx domain) by doing various experiments. Drift diffusion model, Maxwell's equation based optical model, SRH (Shockley-Read-Hall) model which has been used in this software, has been crosschecked with analytical solutions. In our work, by changing the layer of thickness of PEDOT: PSS (poly(3,4-ethylenedioxythiophene)) and the active layer P_3HT: PCBM (poly (3-hexylthiophene): phenyl-C61-butyric acid methyl ester) we have investigated the power conversion efficiency.

II. DEVICE SIMULATION PARAMETERS

A. Structure of GPVDM Software model

To see the changing effect of layer thickness, we have established a simulation model using GPVDM. The model has two parts, I) The graphical interface, II) The back-end solver. Graphical interface is where we edit all the input parameters. It also shows us the result by using python program. Back-end solver is the place where all the calculations of GPVDM is done. It is written in C program.

B. Electrical Model

To perform the device simulation, the built-in potential, charge carrier transport, carrier tapping, free to free carrier recombination of the device are needed to be calculated. In GPVDM software, solar cell simulation is done by solving these basic equations. Poisson's equation is given by-

$$\frac{d}{dx}\,\varepsilon_0\varepsilon_r\,\frac{d\phi}{dx} = q(n-p) \qquad (1)$$

Where ε_0 is the permittivity of free space, ε_r is relative permittivity, ϕ is the voltage profile, q is the elementary

charge of electron, n is the free electron concentration and p is the free hole concentration. Equation (2) and (3) are the bipolar drift and diffusion equations for electrons and holes respectively[6].

$$J_n = q\,\mu_e\, n\frac{dE}{dx} + qD_n\frac{dn}{dx} \qquad (2)$$

$$J_p = q\,\mu_p\, p\frac{dE}{dx} - qD_p\frac{dp}{dx} \qquad (3)$$

Where J_n is the electron current density, μ_e is the electron mobility, D_n is the electron diffusion coefficient, J_p is the hole current density, μ_p is the hole mobility, D_p is the hole diffusion coefficient and E is electric field. Equation (4) and (5) are the electron and hole continuity equations in 1D and time domain.

$$\frac{dJ_n}{dx} = q\left(R_n - G + \frac{dn}{dt}\right) \qquad (4)$$

$$\frac{dJ_p}{dx} = -q\left(R_p - G + \frac{dp}{dt}\right) \qquad (5)$$

Where, R_n is the net recombination rate for electrons, R_p is the net recombination rate for holes and G is the free carrier generation rate. The details of the above equations can be found.

The 3-D graphical representation of the planner heterojunction architecture of our solar model is shown in figure-1. Here P_3HT:PCBM is the active layer. The layers configuration used in this simulation are respectively ITO/PEDOT:PSS/P3HT:PCBM/Al. Here, ITO (Indium Tin Oxide) is the oxide layer, PEDOT:PSS is the polymers blending with P3HT:PCBM and Al is the metal layer. Initially the layer thickness of PEDOT:PSS is preset to 1×10^{-7} m, P_3HT:PCBM to 2.2×10^{-7} m, ITO and Al both are preset to 1×10^{-7} m by default in the simulator. The values are given below in Table-1.

TABLE I: SIMULATION PARAMETER

Layer Name	Thickness (m)	Layer Type
ITO	1×10^{-7}	Contact Layer
PEDOT:PSS	1×10^{-7}	Polymer Layer
P_3HT:PCBM	2.2×10^{-7}	Active/Blending Layer
Al	1×10^{-7}	Contact Layer

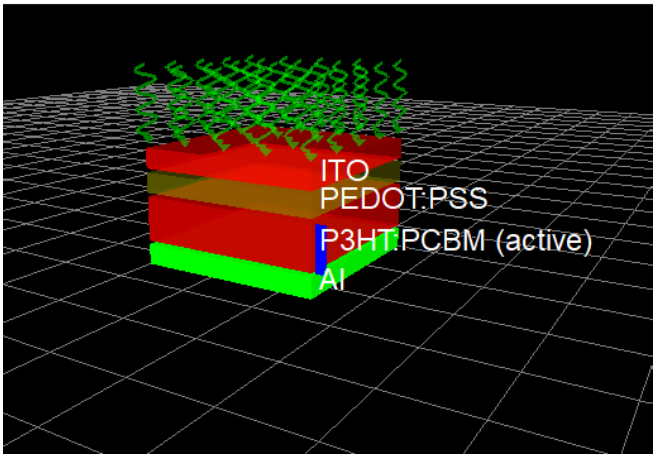

Fig-1: The planner heterojunction architecture of P_3HT:PCBM based solar cell.

In our work, we have varied both the active layer and the polymer layer thickness. We first kept PEDOT:PSS layer fixed at 6 different thicknesses and varied P_3HT:PCBM layer under each thickness (case-I). Then again we kept P_3HT:PCBM layer fixed at 6 different thicknesses and varied PEDOT:PSS layer (case-II). For individual data sets, we have obtained PCE curves.

III. Result And Discussion

In general studies, a common model P_3HT:PCBM (only active layer) structure is used [5]. But here, in case-I, we varied P_3HT:PCBM (active layer) for 6 different values of PEDOT:PSS (polymer layer). Varying P_3HT:PCBM layer thickness from 1.2×10^{-7} m to 10.2×10^{-7} m while PEDOT:PSS layer is fixed at 1×10^{-7} m we have obtained the maximum efficiency curve. From our data we observed that P_3HT:PCBM layer thickness of 2.2×10^{-7} m and PEDOT:PSS layer thickness of 1×10^{-7} m gives us the maximum PCE point of 4.50% (which is by default set in GPVDM), with voltage at maximum power = 0.468738 V, an open circuit voltage of = 0.602238 V and a short circuit current of = -111.634936 A/m^2. Figure-2 shows the graphical comparison among different layer thickness and their effects on PCE. It can be seen from Figure-2 that when PEDOT:PSS layer is fixed at 2×10^{-7} m, there is a sudden increase in PCE at 8.2×10^{-7} m layer thickness of P3HT:PCBM, but not so significant (2.4%). In case-II, we kept P_3HT:PCBM layer fixed at 6 points and varied PEDOT:PSS layer from 1×10^{-7} m to 10×10^{-7} m and plotted the values following the same procedure. Figure-3 shows the PCE curve of data from case-II.

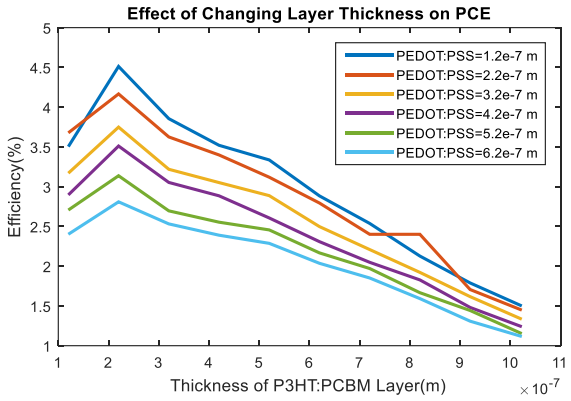

Fig-2: case-I where PEDOT:PSS layer is kept fixed and P_3HT:PCBM is varied for each thickness-PCE curve.

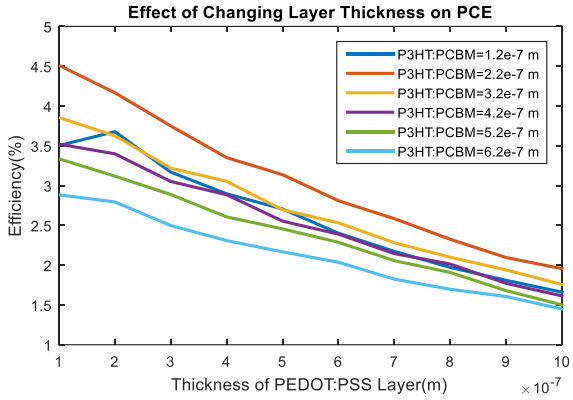

Fig-3: case-II where P_3HT:PCBM layer is kept fixed and PEDOT:PSS is varied for each thickness-PCE curve.

In case-II we can note that when P_3HT:PCBM layer thickness is 2.2×10^{-7} m and PEDOT:PSS layer thickness is 1×10^{-7} m PCE reaches to the maximum of 4.50% which is similar as case-I, then decreases gradually. If we compare the two curves, we can distinguish the better PCE output easily. It is clear from both curves that the rate of decrease of PCE in case-I is higher than case-II. The lowest PCE in case-II is 1.449% which is higher than the lowest PCE found in case-I, 1.121%. The I-V characteristics curve at maximum efficiency point is given in Figure-4.

IV. Conclusion

We have analyzed the Power Conversion Efficiency of a P_3HT:PCBM based BHJ solar cell in our work. The results show that a proper choice of active layer and blending layer thickness can give us an optimum output and increase the efficiency. From the layer thickness- PCE curve, we can note that increasing layer thickness can drop the PCE ratio drastically, as BHJ solar cells deal with thin films.

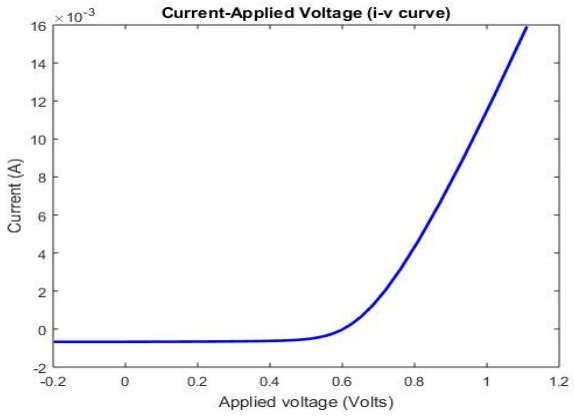

Fig 4: I-V characteristics curve at maximum efficiency point where PEDOT:PSS layer thickness is 1×10^{-7} m and P_3HT:PCBM layer thickness is 2.2×10^{-7} m

We also can conclude from our analysis that changing the polymer layer (PEDOT:PSS) thickness keeping the active layer (P_3HT:PCBM) fixed can give a better PCE output rather than changing the active layer thickness. So, if we keep the active layer in an optimum value and change the polymer layer, better PCE can be obtained. In near future more PCE improvement can be done by changing the active material layer and polymer layer.

***Abstract*—The Copper Zinc Tin Sulfide (CZTS) is considered as one of the promising semiconductor materials in Kesterite family for potential solar cells absorber material. This work focuses on the numerical model and simulation of efficient CZTS based thin-film solar cell. Popular thin-film solar cell simulator wxAMPS was used for simulation of (Al:ZnO/i-ZnO/CdS/CZTS/Mo)structured solar cell and the effects of different layer properties on cell performance parameters were analyzed. An optimized cell with 15.84% (%FF=72.86, *Voc*=0.78Volt and *Jsc*=27.98 mA/cm^2) energy conversion efficiency has proposed. The temperature coefficient (TC) of 0.02%/°C had shown the higher stability of the proposed cell. All of the simulated results had encouraged towards fabrication of high performance thin-film CZTS solar cells.**

Keywords*— *Thin-film solar cell, CZTS, Numerical Simulation, wxAMPS, Conversion efficiency

I. Introduction

The world is approaching towards big crisis of energy as most of the conventional energy resources are going to be depleted. In this situation, solar photovoltaic is one of the most effective ways for the direct power generation from the sunlight. In recent years, photovoltaic keeps on being one of the quickest developing ventures with development rates beyond 40% per year [1].

Among the photovoltaic technologies, Thin-film Solar Cells (TFSCs) have gained popularity for its material usage in a lower scale. Popular TFSCs are Chalcopyrite based polycrystalline binary semiconductor material CdTe (Cadmium Telluride) and quaternary semiconductor material $Cu_2In_xGa_{1-x}Se_2$ (CIGS) is commercially successful. However, there are some restrictions on the usage of limited material Indium (In) and Tellurium (Te) which are raised problems about restriction on generation limit of Photovoltaic (PV) cells.

For solving the issues, Cu_2ZnSnS_4 (CZTS), a quaternary semiconductor material consists of earth abundant material Zn and Sn is one of the hot candidates for PV technology. Abundance of Sn and Zn in earth is very much higher than In (45 times and 1500 times correspondingly) and the price of Indium is almost in the order of twice higher than Sn and Zn [2]. Bandgap energy of CZTS is in the range of 1.4eV to 1.5eV which is suitable for photovoltaic conversion [3]. Furthermore high absorbance capability (absorption coefficient, α is more than 10^6/m) ensures the good possibility of photovoltaic conversion.

Multiphase defects or impurities like ternary and quaternary compounds are more easily formed than CZTS formation. So, pure CZTS crystal formation is a very challenging task and it is formed in a narrow region [2-3].

Highest conversion efficiency of CZTS based photovoltaic solar cell is 10% (confirmed) and 11% (notable exceptions) were fabricated by UNSW [4], Australia whereas William Shockley and S. J. Queisser gives the limiting value of conversion efficiency of single junction solar cell is 30% [5-6]. So there is a huge scope to explore the performance of CZTS based photovoltaic solar cells.

In this research paper, Numerical simulation of CZTS based solar cells has been done with solar device simulator wxAMPS. The cells are simulated by varying the properties of different layers and the important performance parameters were analyzed.

II. Device Structure and Materials

A. Basic Format of CZTS solar Photovoltaic Cell

The photovoltaic effect in heterodiode consists of transparent conducting oxide: Cadmium Tin Oxide (CTO) and CZTS thin film is first reported by Ito and Nakezawa [7]. P-CZTS material is the main absorber layer in CZTS solar cell. The general structure of CZTS based solar cell (Aluminum doped ZnO/intrinsic-ZnO/CdS/CZTS/Mo/Glass substrate) is shown in Fig.1.

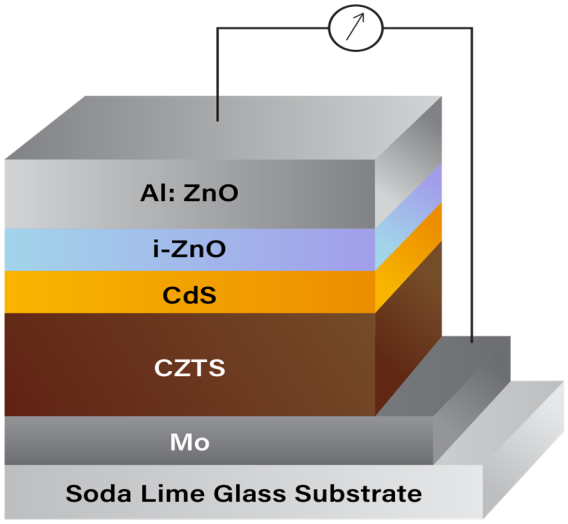

Fig.1. CZTS solar cell structure (thickness is not scaled)

CdS and CZTS are the buffer and absorber layer respectively form the p-n junction and constitute the key part of the device. Aluminum doped ZnO is transparent conducting oxide which creates an n-n+ junction before metal semiconductor contact junction, ensures a low resistive contact for electron transport. The whole structure should be grown layer by layer into a substrate to form a stable structure, because the layer thickness is in the order of nm to µm scale, the cell has no rigidity or mechanical strength of

its own. Usually cell deposited on glass substrate for mechanical strength.

B. Device Modeling and Simulation

Before any type of expensive fabrication, the performance of a cell can be estimated by numerical simulation. For simulation, electrical modeling of layers is needed. Popular solar cell simulator wxAMPS (Analysis of Microelectronic and Photonic Structures with wxWidgets) was used in this work. The wxAMPS is a refresh variant of well-known simulator AMPS (Analysis of Microelectronic and Photonic Structures) created by S. Fonash and refreshed by Angus Rockett [8]. Calculation of wxAMPS is altered by consolidating Newton and Gummel techniques and is a decent apparatus to break down various sorts of solar photovoltaic cells, for example, CdTe and CIGS thin films and different materials. Intra band tunneling model in wxAMPS works extremely well for solar cells of low deformity, for example, CIGS and CdTe Solar cells [9].

In this paper we consider a basic structure of CZTS absorber material based TFSCs consists of CdS heteropartner as described in Fig.1. Material properties utilized in this simulation, which depended on literature, experiments [10-13] and in some case, based on reasonable estimations. Electrical properties of different layers are shown in TABLE I.

TABLE I: OPTIMIZED ELECTRICAL PROPERTIES OF DIFFERENT LAYERS OF CZTS PV CELL

	Layers			
Layer Properties	Al:ZnO	i-ZnO	CdS	CZTS
Thickness (μm)	0.1	0.06	0.06	1.8
Energy Bandgap, E_g (eV)	3.3	3.3	2.4	1.5
Electron Affinity, χ (eV)	4.4	4.4	4.2	4.3
Relative Permittivity, ε_r	9	9	10	7
Density of states in CB, N_c (cm^{-3})	2.22×10^{18}	2.22×10^{18}	2.22×10^{18}	2.22×10^{18}
Density of states in VB, N_v (cm^{-3})	1.78×10^{19}	1.78×10^{19}	1.78×10^{19}	1.78×10^{19}
Electron and Hole Mobility, μ_n and μ_p ($cm^2/v/s$)	100 and 25	100 and 25	100 and 25	100 and 25
Doping Density, N_a or N_d (cm^{-3})	10^{20} (D)	10^{18} (D)	10^{18} (D)	10^{16} (A)

The symbol D means donor and A means acceptor in TABLE I.

The simulation works are done by indicating the device structure and electrical and optical parameters of materials as input contentions of the test system. At that point determined the energy band diagram, recombination profile and transport properties are determined based on the Poisson equation just as continuity conditions. Recombination in profound mass dimensions and their occupation are portrayed by Shockley-Read-Hall (SRH) recombination concept.

III. RESULT AND DISCUSSIONS

Simulations were done in wxAMPS environment to examine the effect of different layer properties on cell performance. Further the results were analyzed to fit an optimized result.

A. Effect of thickness of Al:ZnO(AZO)

To investigate the effect of Aluminum doped ZnO (AZO) layer thickness on the performance parameters of the cell, simulations were done in wxAMPS for different thickness of AZO varying from 50 nm to 500 nm while all other properties of different layers of the cell were kept constant. The simulation results are shown in Fig.2.

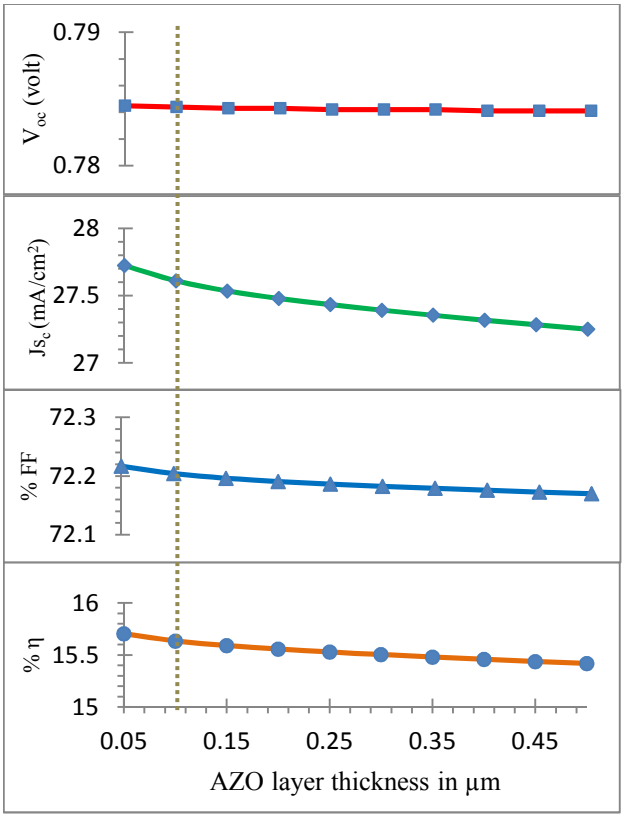

Fig.2. Performance parameters versus AZO layer thickness

The simulation result shows that V_{oc}, J_{sc} and FF are shrinked with the growth of AZO due to the higher absorption of light in the low wavelength region of sun spectrum. So the AZO thickness has been chosen in the lower value (100 nm) which can be easily deposited by popular deposition technique sputtering.

B. Effect of thickness of CdS layer

Cadmium Sulfide (CdS) having a bandgap energy of around 2.42eV, guarantee most of the incident light assorted towards junction. Hypothetically, n-layer thickness ought to be minimal to recoil the series resistance of the device. In the meantime a decreased thickness of CdS allows low absorption in the blue region of the sun spectrum as well as improved short circuit current density, J_{sc}.

Simulations were done by varying the thickness of CdS from 50 nm to 200 nm and the effects in performance parameters were observed. Obtained simulated results are shown in Fig.3.

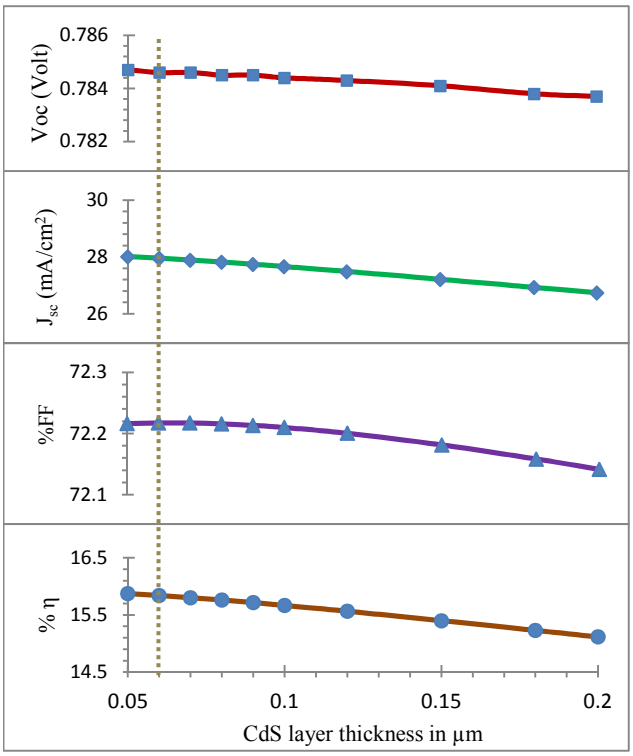

Fig.3. Effect of CdS layer thickenss on cell performance

The simulation results shows that V_{oc}, J_{sc} and FF are shrinked with the growth of CdS as described in the previous paragraph. So the CdS thickness has been chosen in the lower value (60 nm) which can be easily deposited by very popular and cheap deposition technique named Chemical Bath Deposition (CBD).

C. *Effect of absorber layer (CZTS) thickness*

To get acceptable photo conversion efficiency with thin absorber layer is one of the main challenges of thin-film PV cells. The reliance of performance of CZTS solar PV cell on the absorber thickness is considered by changing the CZTS layer thickness differs from 0.1µm to 3 µm while other parameters of the layer as well as other layers are kept unaltered. The results are shown in Fig.4.

It is noted that the V_{oc} and J_{sc} increased with absorber layer thickness due to the large amount of absorption in the longer wavelength region of the sun spectrum and more electron-hole pair generation. Due to the increment of both V_{oc} and J_{sc}, efficiency has been also improved with increasing thickness of the absorber layer. For CZTS thickness greater than 1.8µm, efficiency has shown a decreasing trend due to the bulk recombination and then the decreasing trend of fill factor dominates for thicker absorber layer. Bulk use of materials means more costly device, then the cost of device plays an important factor and a trade of between efficiency and cost should be considered in design.

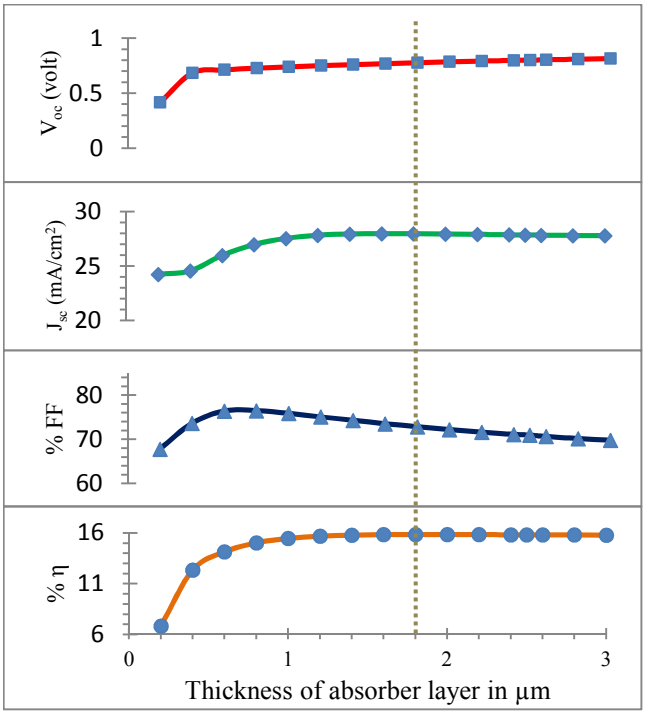

Fig.4. Dependency of Performance parameters on absorber layer thickness

D. *CZTS doping density*

Further simulations were done in wxAMPS to investigate the effect of absorber layer doping profile from 10^{14} cm^{-3} to 10^{17} cm^{-3} in the performance parameters while all other properties of CZTS as well as other layers were kept unchanged. The results are shown in Fig.5.

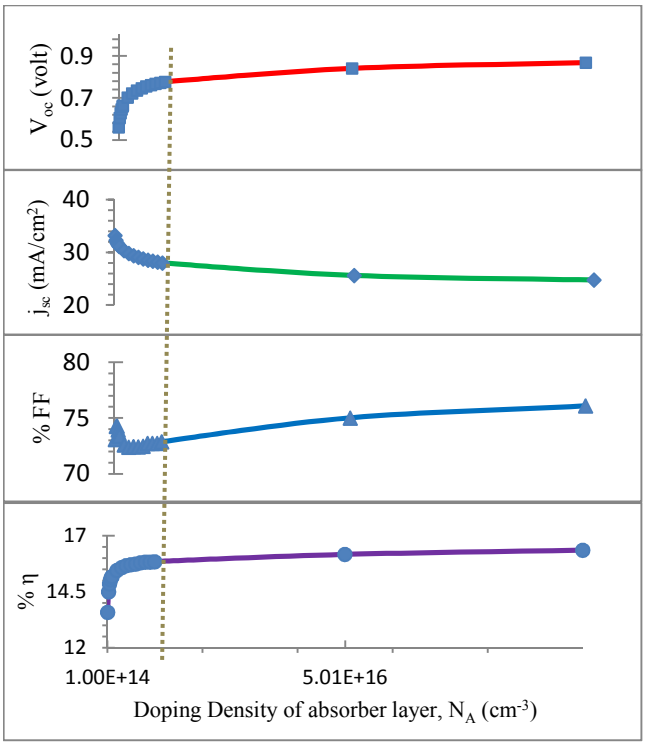

Fig.5. Performance parameters versus absorber layer doping profile

Fig.5. illustrates that the open circuit voltage has increased while the short circuit current density has decreased with the doping profile of CZTS. Fig.6. is an alternative representation of the dependency of V_{oc} and J_{sc} with doping profile of absorber layer. A series of J-V curves are illustrated in a same plot for different doping profile of CZTS absorber.

Dependency of V_{oc} with absorber doping (N_A) can be analyzed as in (1), where I_L is photo generated current and I_o is diode saturation current which is inversely proportional to doping concentration, N_A.

$$v_{oc} = \frac{KT}{q} \ln\left(\frac{I_L}{I_o} + 1\right) \quad (1)$$

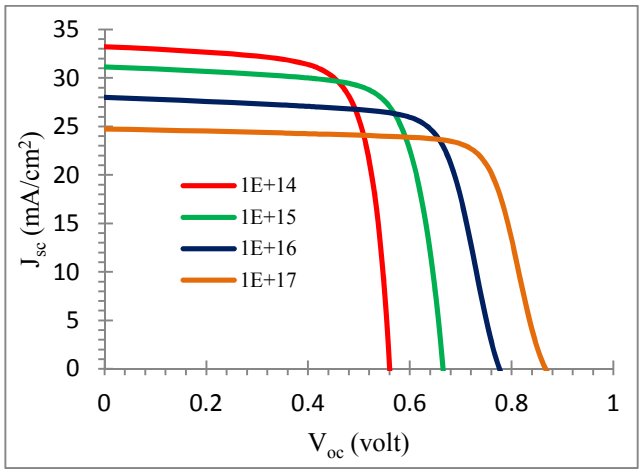

Fig.6.Representation of J-V curves for different doping profile of CZTS absorber layer

It is clear from Fig.6 that I_o is decreased with larger doping profile of the absorber layer and further reduction in I_o causes higher V_{oc} for higher N_A according to the equation 1 as well as simulation results show the same trend of V_{oc} as shown in Fig.5. and Fig.6. Short circuit current density, J_{sc} is decreased with increasing doping density due to the enhanced recombination probability. This will create an obstacle in the path of electron transport and hence reduces the J_{sc}. Disturbance in carrier transport as well as recombination also reduces the external quantum efficiency. The value of N_A had set at 10^{16} cm^{-3} because fabrication of CZTS with heavy doping is very tough.

E. Effect of absorber layer defect density in cell performance

There are so many studies in literature demonstrated that the donor type imperfections were formed strongly than the acceptor type in CZTS material [10]. So the single acceptor type defect is introduced to analyze the defect state of CZTS absorber. The effect of defect density of CZTS in performance is presented in Fig.7.

It is observed that the V_{oc} and J_{sc} are not affected strongly in low level defect but for the defect level 10^{14} and higher, the V_{oc} and J_{sc} were abruptly affected by the defect states as well as the cell performance was strongly diminished. The possible reason is a large no of trap states which further causes huge recombination of photo-generated carrier as well as reduction in J_{sc}, V_{oc} and finally the conversion efficiency.

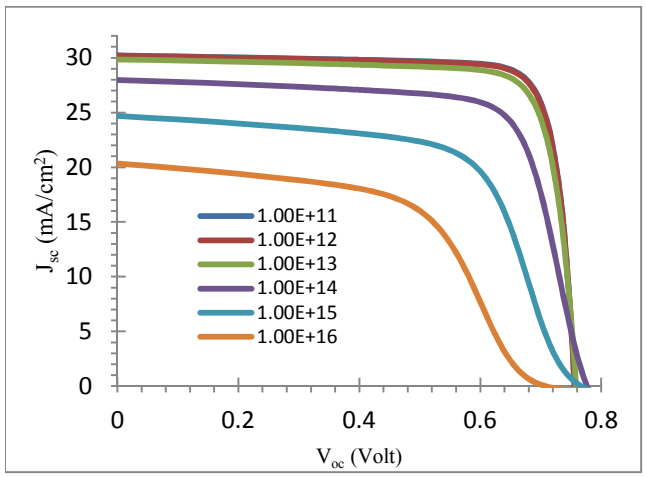

Fig.7. A series of J-V curves with variety of CZTS defect density

F. Effect of absorber layer thickness on Quantum Efficiency

Fig.8. shows a series of external quantum efficiency curves for different thickness of CIGS absorber layer. Visible change in quantum efficiency has occurred up to 1.5µm thickness of CZTS absorber. Variation in CZTS layer thickness affects the external quantum efficiency because higher absorber layer thickness results in more photon generated carrier which offers good possibility to get more carriers in the external circuit.

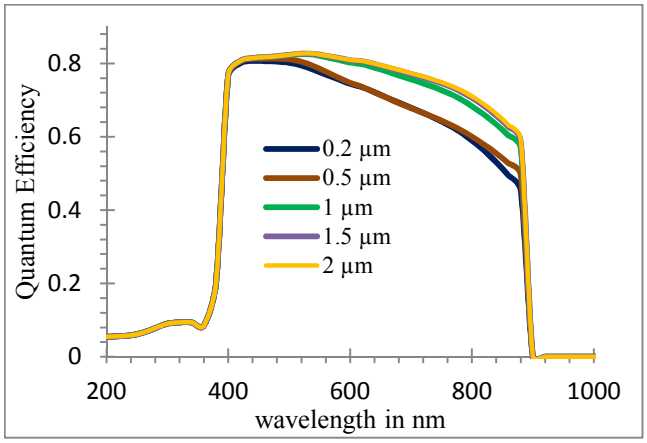

Fig.8. External Quantum Efficiency of CZTS solar cell for different thickness of CZTS

But no visible change has been observed in the quantum efficiency curve for CZTS thickness of more than 1.5µm due to the dominating bulk recombination than the photon generated carrier.

G. Thermal stability of the proposed cell

So as to investigate the stability of the optimized CZTS solar photovoltaic cell with increasing operating temperature, simulations were done in wxAMPS by varying the operating temperature of the cell from 25°C to 125°C and the result is shown in Fig.9.

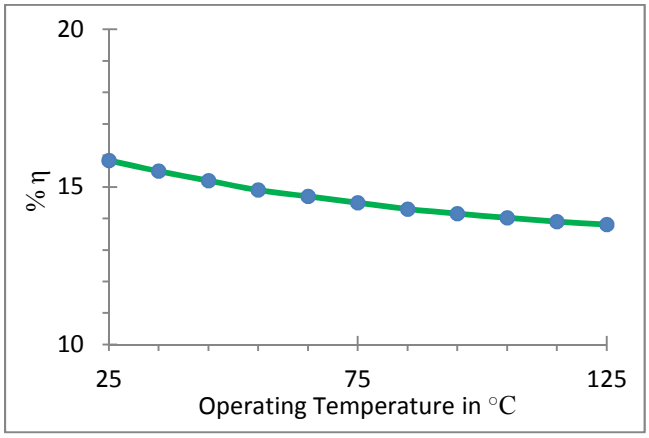

Fig.9. Thermal stability analysis of the optimized CZTS cell

The simulation result points that the optimized CZTS solar photovoltaic cell shows very superior stability with higher operating temperature. The temperature coefficient was calculated as 0.02%/°C from the numerical simulation.

H. Energy band structure of the simulated cell

Energy band structure of the simulated cell as illustrated in Fig.1. is shown in Fig.10.

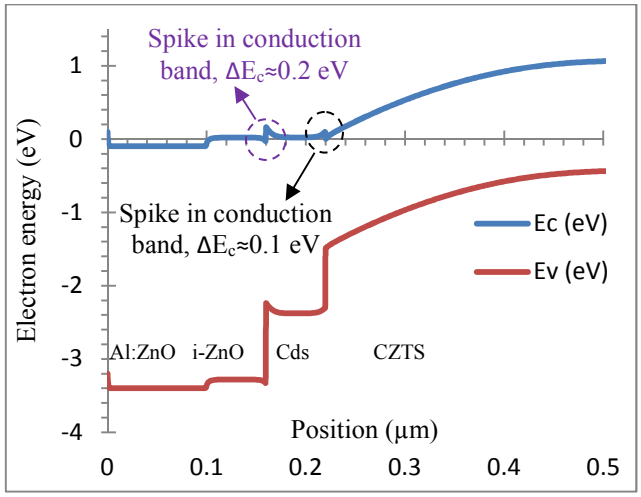

Fig.10. Energy band structure of CZTS solar cell as shown in Fig.1

Positive conduction band discontinuity ($\Delta E_c = \chi_1 - \chi_2$, where χ_1 and χ_2 are electron affinities of CZTS and CdS layer correspondingly) creates a spike in the conduction band in the CdS-CZTS heterointerface and also in CdS-i:ZnO heterointerface as shown in Fig.10. A cliff in the conduction band near absorber layer enhances interface recombination in chalcopyrite based solar photovoltaic cell consists of wide bandgap material [14]. As ΔE_c is 0.1 eV and 0.2eV here and the spike energy more than 0.3 eV is not good for carrier transport, so it doesn't create any obstracle in carrier transport and additionally it creates an electric field which further accelerates carrier transport in the heterointerface.

IV. Conclusion

Basic structure of thin-film CZTS solar cell with CdS buffer layer was modeled and simulated by varying different layer properties. The impact of different layer thickness on conversion efficiency and othe performance parameters were investigated. The dependancy of doping concentration and defect dencity of CZTS absorber layer were also investigated and analyzed. Simulation shows that 15.84 % (*FF*=72.86%, J_{sc}=27.98 mA/cm^2, *and* V_{oc}=0.78 Volt) conversion efficiency has been achieved for the optimized cell. The simulated cell with optimized layer properties presents a better conversion efficiency of 15.84% as compared to the counterparts [4] and the layers as well as the device can be fabricated by different popular deposition techniques like sputtering and chemical bath deposition.

***Abstract*—The use of Electric Vehicles (EV) as transport is an eco-sustainable and plausible way to protect the reserved energy of developing countries such as Bangladesh. Being a tropical country, Bangladesh is remarkable for its abundance of solar radiation. By using this enormous amount of renewable energy, we can reduce the current power crisis. At present, EVs are running in Bangladesh are auto rickshaw and easy bike. Although these easy bikes and auto rickshaw seem eco - friendly, they are partly responsible for environmental pollution as they use grid power. Under this circumstance, the establishment of Solar Charge Station (SCS) for EVs will be a perfect solution. Because it reduces the additional pressure on the grid by charging directly the EVs and thus saves the environment is polluted.**

Keywords—Solar Charge Station, Electric Vehicles, Grid Power.

I. INTRODUCTION

In the most recent decade, two critical issues developed in the wording of vitality all through the world. The first one is running out of limited petroleum in the near future and the other one is carbon discharge result in a worldwide temperature alteration. Numerous nations at this time rely vigorously on oil, coal and aerosolized gasoline for its energy source. Petroleum derivatives are non-renewable. Non-renewable energy sources are non-sustainable, they draw on restricted assets which will, within the future, diminish, turning into too expensive or too earth harming, creating it not possible to recover. There are many petroleum consumption sectors. Transportation is one of them. As reported by The Energy Information Administration (EIA), around 29% of U.S. energy expenditure in 2017 was for transporting individuals and product from one place to another [1]. At present main transportation vehicles are running by a combustion engine. This combustion engine is 25-30% efficient [2]. In contrast, EV is more efficient up to 85% due to high motor efficiency[3]. According to The National Transportation Research Center (NTRC), World consumes 27706.5 Trillion Btu of energy for transportation and about 6.6 GT CO_2 is emitted [4] whereas EV is environmentally friendly and has a low noise level. Developing countries such as Bangladesh have faced power crises from the last twenty years [5]. Charging these electric vehicles causes an additional load on the national power grid and, as a result, an enormous load shadow experience for the people of the country. It is, therefore, necessary to recharge these EVs from an alternative energy source such as the country's renewable energy resources. Of all renewable energy sources in Bangladesh, solar energy has the highest potential. Therefore, Solar Charge Station (SCS) is a sound solution to this problem.

II. ELECTRIC VEHICLE

Electric vehicles use Electric motors to power their wheels. They drive part or all of the energy from large rechargeable batteries. Electric vehicles are a promising technology to reduce emissions of greenhouse gases and other environmental impacts due to road transport. Each vehicle consumes at best five watts of electricity during off-peak hours to recharge the batteries and 50,000 bikes consume at best 25 megawatts [6]. This causes an additional load on the national power grid. Totally driving an EV from the grid is certainly not a decent way that is followed in Bangladesh. That's why simply it is good thinking to implement solar charge station by using unused place and on the roof fueling station.

III. SITE SELECTION

The choice of the location for an EV charging station is an important factor. A good location can increase both the demand for charging stations and their popularity [7-8]. In this paper, a few criteria are resolved for choosing the area of EV Charge Station Factors of Location Selection [9-10]:

- Level of Charger
- Type of Destination
- Clientele
- Cost of Installation and Operation
- Local Infrastructure and Future Plans
- Engineering Feasibility
- Service Availability
- Geographical Environment

The site meets the above criteria; it will be perfect for solar

charge station. One place can't fulfill above all conditions. Therefore, optimization on the basis of the available location is necessary. For the Charge Station, our selected location is 'Faridpur Engineering College, Faridpur'. Field data were collected from this site and this data may differ slightly from other sites in Bangladesh.

A. Potential of Solar Energy

Bangladesh is located between 20°34′ to 26°38′ north latitude & 88°01′ to 92°41′ east longitude and has a total area of 1.4757×10^8 m^2. On an average of 5 kWh /m^2 solar radiation falls on this country over 300 days per annum. Solar Energy is a pollution free source of renewable energy and it is available everywhere. At present condition, usage of energy in Bangladesh is about 0.15 watt/sq. meter land area, whereas the opportunity is on top of 208 watts/sq. meter [11]. Therefore, this abundant solar energy has a large potential to be used in a various sector in Bangladesh reducing the traditional fossil fuel-based power consumption and ensuring a green environment for the future generation. According to NASA Surface, Meteorology and Energy solar monthly averaged radiation incident (kWh/m^2/day) is shown below throughout the year (January 1984-December 2013) in Faridpur is shown in Table I below [12].

TABLE I. SOLAR RADIATION THROUGHOUT THE YEAR IN FARIDPUR CITY

Month	Average Solar Radiation (kWh/m^2/day)	Month	Average Solar Radiation (kWh/m^2/day)
January	6.18	July	2.58
February	6.15	August	2.77
March	6.08	September	2.93
April	5.58	October	4.42
May	4.49	November	5.74
June	3.03	December	6.47

B. Potential of Wind Energy

Wind turbine systems give a supply of renewable energy. they're most adapted to gusty rural areas. At optimum action, the efficiency of a aerogenerator in converting wind energy to electricity is about 45% [13]. Studies have found that wind energy can play a vital role as an assistance resource for solar energy to generate power for this charge station [14].

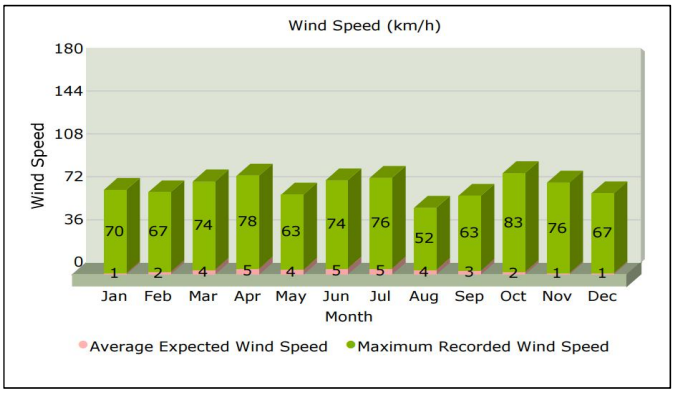

Fig. 1. The Wind Speed (km/h) Data in Faridpur

The potential of wind energy in the coastal areas of Bangladesh is very high but experimentally measured wind speed data are not available over Bangladesh. Wind energy potential in our proposed location is the moderate level. The Wind Speed (km/h) data for various months throughout the year in Faridpur is shown in Fig.1 [15].

IV. METHODOLOGY

PV Panel is the main element of the Solar charge Station. It is connected Series and parallel to equivalent the system voltage by array connection box. To maintain the DC battery charging system and DC load, the MPPT charge controller is used. A 3-phase pure sine wave inverter inverts DC to AC for operating the AC load from main distribution to the sub-distribution board.

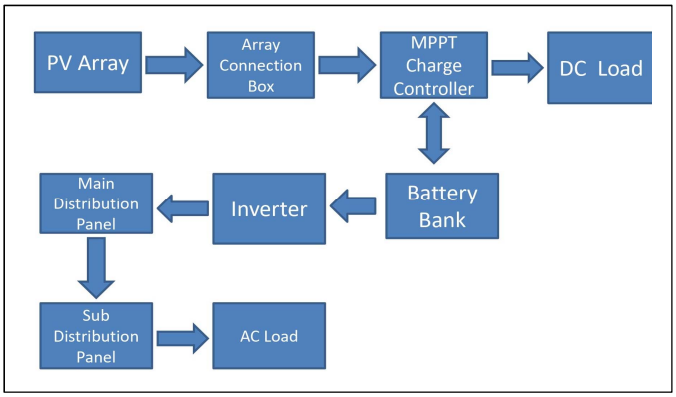

Fig. 2. The Basic Operational Block Diagram

V. ENERGY CONSUMPTION OF ELECTRIC VEHICLE

At present EVs are used in Bangladesh are easy bikes and auto rickshaws. This paper apprizes the approximate energy consumption of an easy bike used in Bangladesh.

Number of Battery used in an easy bike = 5 pcs

The rated voltage of battery = 12 V

The current capacity of battery = 140 Amp-hour

So, the energy stored in each battery

$= \{(140 \times 12) \div 1000\}$ kWh
$= 1.68$ kWh

Now, the total energy consumption of an easy bike

$= (5 \times 1.68)$ kWh
$= 8.4$ kWh

Let the efficiency of solar charge controller is about 90%.

So, charge controller loss = $\{(10 \div 100) \times 8.4\}$ kWh = 0.84 kWh

Therefore, overall energy consumption of an easy bike

$= (8.4 + 0.84)$ kWh
$= 9.24$ kWh

The proposed solar charge station can able to charge a maximum of twenty vehicles at a time. So, the maximum demand of energy consumption is 184.8 kWh. By considering some extra demand, the capacity for reliable operation of the SCS is 200 kWh.

VI. Modelling Of Pv Module

We take a solar PV module, model of SM280-18V with rated power (Pp) of 280W. The average sun hour (ASH) in the selected location is 8 hours. The peak watt Pp is given under standard cell temperature condition (Tc = 25°C), but solar cells are usually 10-30°C hotter than the day time ambient temperature due to solar heating. If the ambient air is 30°C, the cell temperature, Tc could be expected to rise to 40-60 °C [16]. So temperature correction is required. The number of required modules considering the cell temperature (Tc) effect and overall efficiency (η), is then given by [17]

$$N = \frac{Daily\ load\ energy\ demand\ in\ kWh}{Panel\ rated\ power \times AverageSun\ Suning\ Hour}$$

$$= \frac{load\ demand\ in\ kWh}{Pp \times ASH \times [1-(Tc-25)\ 0.5\%] \times \eta}$$

$$= \frac{load\ demand\ in\ kWh}{2.20kWh \times [1-(Tc-25)\ 0.5\%] \times \eta}$$

$$= \frac{200\ kWh}{2.20kWh \times [1-(60-25)\ 0.5\%] \times 0.8}$$

$$= 135.85 \approx 136$$

For the system voltage is 60 V, the required charging voltage is about 70 V. The rated output voltage of the panel is 18 V. The series of 4 solar PV module give 72 V. Hence the number of parallel string = (136 ÷ 4) = 34. So, the total number of solar panel required = 136.

VII. Modelling Of Battery Bank

The number of the battery (N_b) required for a PV system is calculated by considering daily load energy demand, Rated battery voltage (V_b), Battery ampere hour rating (B_{ah}) & overall efficiency of the battery (η_b = 90%) prescribed.

$$N_b = \frac{Daily\ Load\ Enegy\ Demad}{Vb \times Bah \times \eta b} = \frac{200kWh}{12 \times 130 \times 0.9} = 142.15 \approx 145.$$

Then the number of battery required = 145. To maintaining charging system voltage, 5 batteries are connected in series by 29 rows.

VIII. Cost Analysis Of Charging Station

The cost of various components with respect to quantity are given in Table II. The installation, civil work, wiring and maintenance cost is considered approximately. The cost of those components may be varied according to its brand, quality and place.

TABLE II. Components Cost Of SCS System

Components	Model	Quantity	Price (BDT)
Solar Panel	SM280W-18V	136	1713600
Battery	PT-130	145	1740000
Battery Stand	Hand made	5	100000
Solar panel Stand	Hand made	10	100000
Charge Controller	Hand made	8	15000
Inverter	Local Made	1	60000
Wiring	Hand made	-	15000
Civil Work	Approximate	-	100000
Technical Cost	Approximate	-	30000
Capital Cost			3873600

The one-year electricity generation data is calculated by daily and monthly in Table III.

TABLE III. Daily And Monthly Electricity Generation

Month	Sun Daylight (hr.)	Daily Energy Generation (kWh)	Monthly Energy Generation (kWh)
January	8.87	337.77	10470.87
February	9.4	357.95	10022.60
March	10.02	381.56	11828.36
April	10.02	381.56	11446.80
May	11.27	429.16	13303.96
June	11.55	439.82	13194.72
July	10.43	397.18	12312.58
August	10.95	416.98	12926.38
September	10.3	392.22	11766.60
October	9.63	366.48	11360.88
November	9.02	343.48	10304.40
December	8.87	337.77	10470.87
Total Generation (kWh)			139409.02

The annual depreciation value of the charging station is calculated for various components in Table IV.

TABLE IV. Depreciation Cost On SCS Component

Equipment's Name	Investment (BDT)	Life Time (Years)	Depreciation Charge (A/S)	Annual Depreciation (BDT)
Solar Panel	1713600	25	0.55%	94248.8
Charge Controller	15000	5	15 %	22580
Battery	1740000	5	15 %	261000
Civil work	50000	25	0.55%	275
Inverter	60000	5	15 %	9000
Total annual depreciation on equipment				281949.8

The total annual operating cost of charging station is determined in Table V.

TABLE V. Annual Operating Cost Of SCS

Total Cost List	Rate of Quantity	Amount in BDT
Annual labor cost	15000 x 12	180000
Maintenance cost at 1.5% of total capital	0.015×3873600	58104
Annual depreciation	-	281949.8
14% Interest of total capital	0.14×3873600	542304
Total fixed charges		1062357.8

The per unit generation cost of annual operation is determined in Table VI.

TABLE VI. Cost Of Per Unit Generation

Total Cost List	Amount of Parameters
(a) Total annual fixed charges	1062357.8 BDT
(b) Energy generation per year	139409.02kWh
Cost of generation (a/b)	7.62 BDT/Unit

IX. Payback Time Calculation

After a fixed time, Cost will be recovered from this project. So, the payback time is very important for any cost implementation project. The payback time is calculated to the capital cost of a system divided by annual cash outcome.

$$\text{Payback Time} = \frac{Capital\ Cost\ of\ Project}{Annual\ Cash\ outcome}$$

If we consider the five-taka unit as electricity price for this charging system-

Then the total annual income = (5 × 39409.02) BDT
= 697045.1 BDT

The system total capital cost = 3873600 BDT

Payback Time = (3873600 ÷ 697045.1) = 5.5 Years

X. Recent Built Solar Charging sation In Bangladesh

With the monetary help of IDCOL and World Bank, Solar E-Technology has started on a tryout project at Chuadanga and organized an exhaustive R & D workout on a solar powered battery charging station as another choice to charge batteries for easy bikes [18].

Fig. 3. Solar Powered Battery Charging Station R & D site at Chuadanga

XI. Conclusion

Day by day, the number of EVs increased rapidly in Bangladesh. It is good news for EVs future but it creates additional demand on the grid & partially liable for power crisis. Although these EVs seem eco - friendly, they are partly responsible for environmental pollution as they use grid power. Because this grid power is generated by natural gas, oil, coal etc. At this moment, if the proposed SCS can full fill the current demand of EVs, it will get its popularity. Then it will be easy to develop a project system model and reduce generation cost.

Abstract— **Hybrid renewable energy systems (HRESs) have a great potentiality to provide a more reliable power supply, when compared to a system based on a standalone source. The hybrid system supports the modular design that can mitigate problems associated with the use of individual sources by combining them all in a systematic procedure. In this paper, comparative study for analyzing the effects of four different systems namely: photovoltaic (PV) stand-alone with storage unit, PV-battery-grid system, PV-diesel-battery system, and PV-diesel-grid system are carried out using the HOMER software. Furthermore, an optimal cost analysis is also conducted based on net present cost (NPC). In addition, using real satellite footage with the help of HELIOSCOPE software, an effective configuration of PV array is designed based on real solar irradiance data. The cost optimization of the HRES is developed on the basis of the sets of real data collected from Khulna University of Engineering and Technology (KUET), Khulna, Bangladesh. The study reveals that the approach with PV-diesel-battery system has comparatively lower NPC, less fuel cost, and a limited carbon footprint along with excess electricity to contribute to the national grid.**

Keywords— HOMER, NPC, HELIOSCOPE, Micro-grid, Hybrid Renewable Energy System.

I. INTRODUCTION

The limited availability of fuel and a gradual increase in its cost has made it necessary to utilize renewable energy for electrical power production [1]. Being inexhaustible in nature and also for overcoming environmental constraints, renewable energies are getting much more interest. Renewable energy system (RES) also provides flexibility of being complimentary, as the integration between them shows tremendous promises [2]. Despite the availability of solar photovoltaic and wind energy, a PV or a wind generator system acting as stand-alone, cannot meet-up the 24 hours demands [3]. This is the reason why research on HRES has come in vigilant.

A HRES usually consists of multiple renewable energy sources carried out together to provide sustainable energy production as well as economic efficiency [4-7]. Additionally, it can also offer extra power to the national grid after meeting up self- demands. But for designing an effective HRES, a lot of factors need to be considered based on load analysis, geographical location as well as weather conditions [8]. Many researchers have already investigated the HRES system model based on different circumstances[9-10]. Economic cost analysis of PV array and wind generator based HRES system for remotely located village has been proposed earlier [11]. But, for areas or institutions such as KUET, which has more sophisticated load demand and also would like to approach toward self-sufficiency in regard to electricity; the implementation of HRES has not yet been studied.

The main purpose of this study is to design, simulate and optimize a system to meet the electrical load demand of KUET premises. In terms of system reliability, economy and environmental issues related to decentralized electrification, evaluations are made to overcome the existing constraints and finding out the best-suited hybrid system configuration. By considering the geographical position of KUET and the existing climate conditions, solar energy has been selected as a promising form of source for power production. Along with it, battery storage system and diesel generator have also been considered for designing the HRES system. Four possible case studies have been analyzed to determining the most effective combination using HOMER software. Additionally, using HELIOSCOPE—another advanced solar design software—

different configurations of PV array on different buildings of KUET have been simulated and analyzed by feeding real solar Irradiance data for that location. By considering the effectiveness and cost-efficiency, the more suitable PV lay-out has been proposed. The protocol that has been proposed here can also be applicable for other institutions and also in industrial premises having the similar kind of load profiles.

The rest part of the paper has been organized as follows: in section II, system modeling along with case study analysis has been provided. Detailed PV array configuration with necessary mathematical illustration has been demonstrated in section III. The later section explains the economic cost analysis for required optimization. Simulation results of the proposed system have been presented in section V. This section also describes the numerical comparison of different cases based on the system parameters. Finally, in section VI, the key features along with brief details have been described as a conclusion.

II. System Modeling and Case Study Analysis

In this paper, systematic model design of a renewable hybrid energy system for KUET campus is configured and optimized using the HOMER software. Alternative system configurations based on different other well-known systems in conjunction with the solar system are also modeled and compared. In general, four different configurations are proposed entitled with case number and thereafter evaluation and comparison are made with some fundamental criteria such as energy efficiency, financial viability, and environmental impact. In Fig. 1, the grid monthly input data has been shown which have been collected from KUET substation. The average demand of KUET in kWh/d is 4907.6 and the peak demand is 967 kW. To analyze and find out the optimal solution using NPC in HOMER software these grid monthly input data has been used. The other input parameters that have been considered for sizing cost and other parameters are standardized from National Renewable Energy Laboratory (NREL) [12]. In Table I, the standard capital costs, replacement costs, and operational and maintenance costs for different units are listed [13]. For all the systematic analysis same PV and diesel parameters are used in all four different cases whenever required.

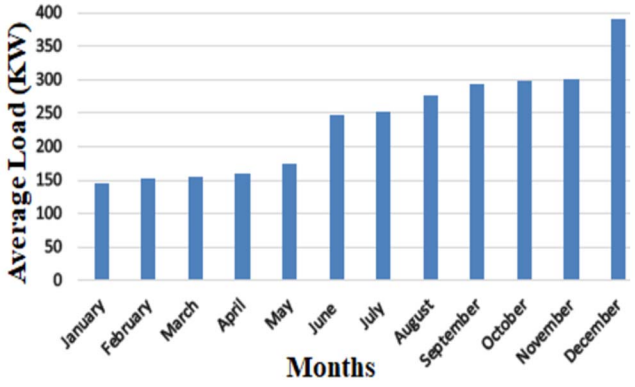

Fig. 1. Monthly load profile of KUET

TABLE I. Input Data for Cost Analysis

Units	Capital Cost	Replacement Cost	Operational & Maintenance Cost	Expected Life time
Diesel Generator	$125/kW	$125/kW	50.15/Hour	9.60y
Battery	$75/Battery	$75/Battery	$2/Battery/Year	510kWh
PV	$7500/kW	$7500/kW	0	25y
Converter	$1000/kW	$1000/kW	$100/Year	15y

In case 1, to meet up the electrical demand of KUET, two solar micro-grids rated at 630 kW and 680 kW along with associated converters and storage units have been considered. As a storage unit 1108 kW battery and 1000 kW converter has been adopted. The hours of operation considered for the converter, having a capacity factor of 23.2%, is 8760 h/year, whereas for PV array it is 4371 h/year. Individual contribution of the two solar micro-grid is to produce 160,612 kWh/year, nevertheless case 1 faces a capacity shortage of around 1448 kWh/year, making it less compatible as a PV stand-alone system. On the other hand, in Case 2, the configuration is same as of Case 1 with an addition of grid connection. In this case the energy is exchanged over the grid i.e. energy is taken from grid when required and also sale to the grid when surplus energy is produced. The purchase and sellback price for this case has been considered as $.10 /kWh and $.05/kWh respectively. The system is designed to feed electricity from the grid during night when the PV is off. The two PV micro-grids produce 7.65% of power separately per year, whereas the rest 84.7% power is purchased from grid.

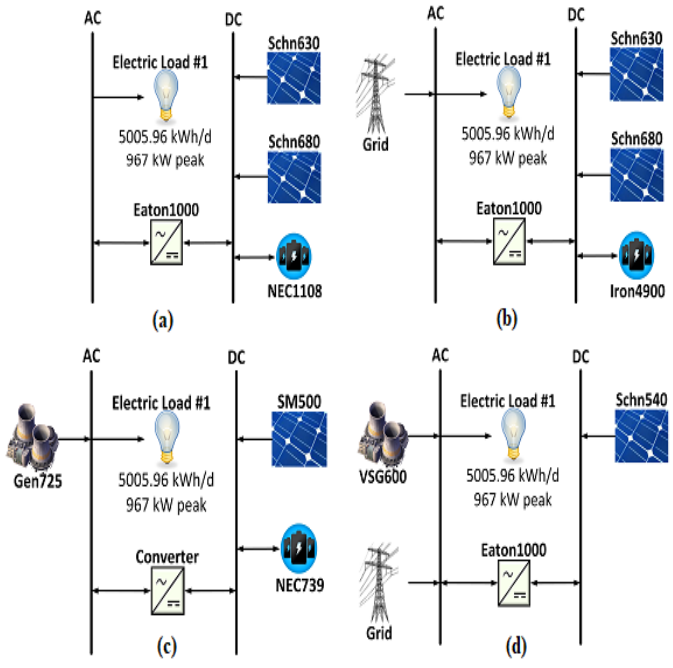

Fig. 2. Proposed hybrid system configurations. (a) PV only with storage system, (b) PV with grid and storage system, (c) PV, diesel generator with storage system, and (d) PV, diesel and grid system

For Case 3, a 725 kW diesel generator along with 500 kW solar micro-grid, 739kW battery storage system, and 1000kW converter are used to mitigate the same load profile. When the solar system is off, the load demand is supplied from diesel generator and storage units. The PV array generates 46.4% of power annually, while the remaining 53.6% production is met by the diesel generator. Lastly, a 600 kW diesel generator, a 540 kW solar micro-grid, the grid connection, and DC/AC converter have been used for Case 4 in the same load profile of the existing electric system of KUET. In this model, 72.1% power per year is required to purchase from grid, the rest are generated by PV cells (8.75%) and diesel generator (19.2%). The model configurations (i.e. cases) are labeled as (a) to (d) and are shown in Fig. 2, by using generic HOMER components. However, it is noteworthy that for all the cases, a 6 percent annual interest rate and built-in constraints have been considered.

III. PV Array Configuration

The solar resource input data for HOMER is made up of monthly averaged daily insolation incidents on a horizontal surface (kWh/m^2/day) from the NASA Surface Meteorology and Solar Energy website [14]. It is noted that NASA provides monthly averaged values from 22 years of data. The standard solar radiation data for the location of KUET ($22°54.0'N, 89°30.1'E$) is shown in Fig. 3. As shown in the figure, the solar radiation is dependent on the day time and pattern of cloud in the geographical area like Bangladesh. HOMER evaluates PV array power for the year on an hourly basis, and uses latitude value to calculate the average daily radiation from the clearness index and vice versa. The annual averaged daily solar insolation in this area was found to be 4.56 kWh/m^2/day.

To find out a sustainable and inoffensive appearance to the beauty of KUET green campus, the proposed solar panels must be arranged thoughtfully. Therefore, careful designs were made to utilize the rooftops of different building of KUET campus. For the 1st and 2nd cases, a 1.3 MW PV array design configurations, and for the 3rd and 4th cases, another 655.2 kW PV array design configuration is required. A specialized software 'HELIOSCOPE' has been employed for this purpose. The HELIOSCOPE design of both the 1.3 MW and 655.2 kW PV array configurations has been illustrated in Fig. 4 and Fig. 5 respectively.

The calculation of output power provided by installed PV array has been determined by utilizing the following equations [15]:

$$T_c = T_a + g(t) \times \left(\frac{T_N - 20}{0.8}\right) \quad (1)$$

$$I = g(t) \times \left(I_{sc} + K_c \times (T_c - 25)\right) \quad (2)$$

$$V = (V_{oc} + K_v \times T_c) \quad (3)$$

$$FF = \frac{V_p \times I_p}{V_{oc} \times I_{sc}} \quad (4)$$

$$P_{pv}(g(t)) = n_{cell} \times FF \times V \times I \quad (5)$$

The above-mentioned parameters are briefly summarized on Table II.

TABLE II. SUMMARY OF DIFFERENT PARAMETERS.

Parameter	Meaning
T_c	cell temperature [°C] of the PV panel
T_a	ambient temperature [°C]
$g(t)$	random irradiance
T_N	nominal temperature for the operation of the PV cell [°C]
V_{oc}	open-circuit voltage [V]
I_{sc}	short-circuit current [A]
K_c	current temperature coefficient [mA/°C]
K_v	voltage temperature coefficient [mV/°C]
V_p	voltage at peak power [V]
I_p	current at peak power [A]
FF	Fill factor
n_{cell}	number of PV cells
V	terminal voltage [V]
I	PV cell current [A]
P_{pv}	PV power output [W]

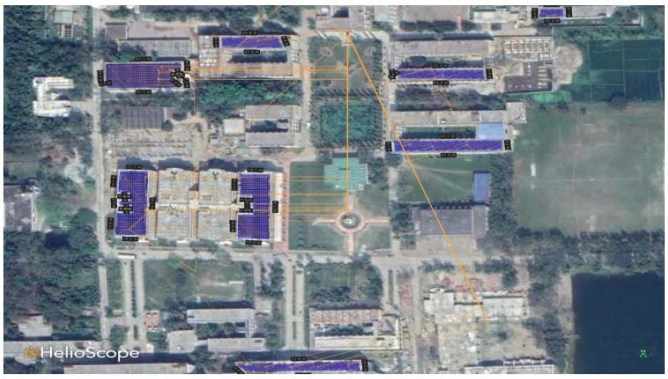

Fig. 5. PV panel installation for cases 3 and 4.

IV. Economic Modeling With Optimization

For optimization, one of the important parameters—low NPC—has been considered for attaining economic feasibility. The value of NPC is determined from all the costs and revenues of the life-cycle of the system. The calculations also accounted for the initial capital cost, maintenance cost, component replacement and fuel costs using the discount rate to calculate the future cash-flows.

The NPC is calculated using the following mathematical relation,

$$NPC = \sum_{t=0}^{T} C_{ct} + C_{om,t} + C_{r,t} + C_{f,t} - R_{s,t} \qquad (6)$$

Here, T is the lifetime of the project, C_{ct} represents the capital cost for the system in year t, $C_{om,t}$ represents the cost of operation and maintenance in year t, the replacement cost at year t is $C_{r,t}$. The other parameters, $C_{f,t}$ is the cost of fuels in year t, and $R_{s,t}$ represents the salvage price in same time period *t*. HOMER performs time series simulation on hourly basis for every possible system configurations, and thereafter finds the optimal solution where the system meets the total energy demand and achieves the least possible NPC. The optimization also provides a list of configurations sorted by the Cost of Electricity (COE) for each of the optimized systems and offers the opportunity to prioritize the system on COE for evaluating the financial feasibility [17]. The COE represents the average production cost of each kWh useful electrical energy produced by the system. COE is basically a ratio of annualized cost of producing electricity to the total useful electric energy production. The relationship of these terms are given as,

$$COE = \frac{C_{tot}}{E_{PAC}+E_{PDC}+E_d+E_g} \qquad (7)$$

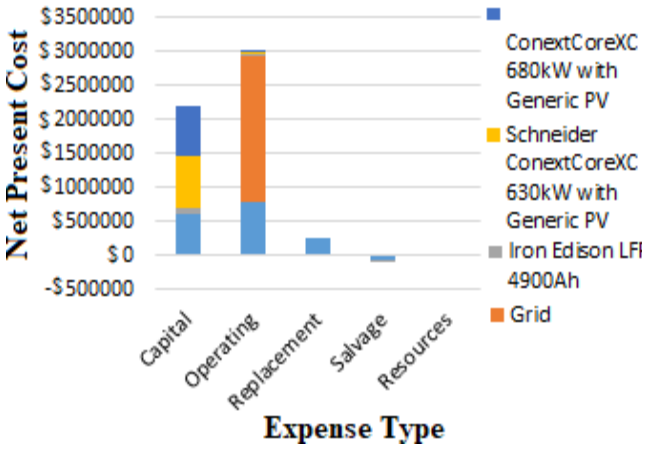
Where C_{tot} is the aggregative amount of the cost of investing is, installing, operating, and maintaining the energy system, E_{PAC} represents the AC electricity demand of the primary load, E_{PDC} is the DC electricity demand of the primary load, E_d denotes the electricity demand of the deferrable load, and E_g represents the electricity sold to the grid.

Another aspect of optimization is to consider the environmental effect for the four cases. As for case 1 and case 2, the produced power mainly depend on solar power, therefore, no CO_2 emission occurs in the process. But for case 3 and case 4 diesel generators are mainly responsible for producing CO_2 emissions. For determining the rate of emission of CO_2, the fundamental step is to evaluate the specific fuel consumption rate for two different cases. The specific fuel consumption (F_{sfc}) can be determined in the following manner [13]:

$$F_{sfc} = \frac{F_T}{E_g} \qquad (8)$$

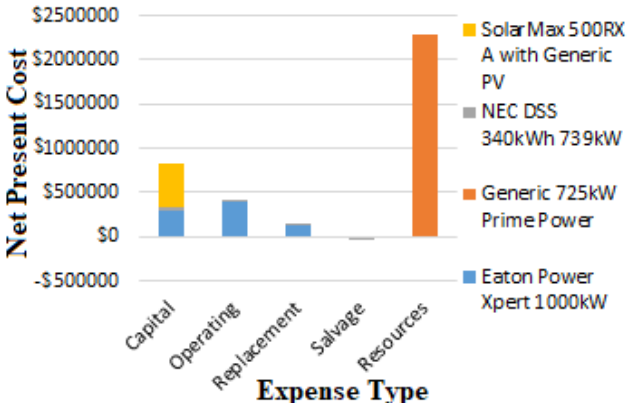
Where, F_T is the total annual fuel consumption [L/year] and E_g represents the annual electrical production [kWh/year], of the generator. Finally, the emission of CO_2 due to fuel consumption can be calculated by taking benefit of the value of specific fuel consumption as shown below [16]:

$$E_{CO_2} = F_{sfc} \times EF \qquad (9)$$

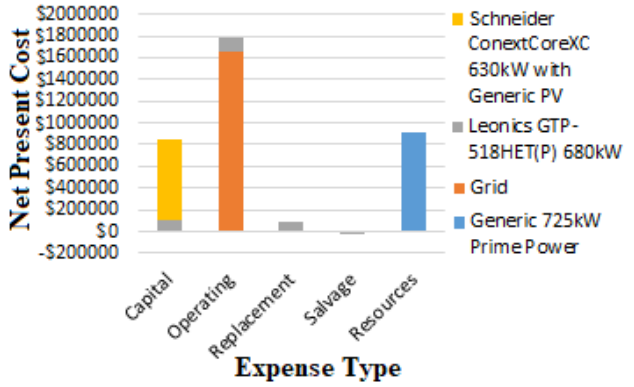


Where, E_{CO_2}: represents the emission of CO_2 [kg/kWh],
EF: Emission factor [kg/L],
F_{sfc}: Specific fuel consumption [kg/kWh].
It is notable to mention that, the emission factor for diesel fuel has been considered as 2.66 kg/L in this paper for calculation.

V. Simulation Results and Discussions



To find out a comprehensive comparison among the proposed cases systematic investigations were carried out. The analysis includes the basic parameters such as NPC, CO_2 emission, and other parameters related to the cost are calculated using HOMER. On the other hand, the system loss due to the fact such as shading, inverter, converter, reflection etc. has been simulated and calculated using HELIOSCOPE. A detailed analysis of the NPC profile is shown in Fig. 6 separately for all the four cases. As it is shown in the Fig. 6(a), the capital cost is much higher than other expenses for case 1, where only two solar micro-grids were used. On contrast, operating costs for 4 is very high due to the running cost of diesel engine. However, most resources with the lowest capital cost are required for case 3 which combined solar, diesel and storage systems.



(a)

(b)

(c)

(d)

Fig. 6. Simulation results of net present cost (NPC) for different expense types: (a) case 1, (b) case 2, (c) case 3, and (4) case 4.

A detail comparison of the costs for the four individual cases is summarized in Table III. The simulation reveals that the case 3 involves an initial cost of $0.83M which is the lowest initial one amongst the four cases. Since the system totally depends on renewable resources in Case 1, the involvement of large number of storage unit i.e. battery led to a higher initial cost. As smaller solar micro-grid integration is considered in Case 3, the initial cost has not been increased significantly. Among the four cases, the fuel cost is involved with the systems with diesel generators. When the renewable fraction increases the fuel cost reduces. Neither the fuel cost nor CO_2 emission is associated with the solar PV only micro-grid configurations. One of the noteworthy features of the analysis is that, despite of having no fuel cost and negligible maintenance cost for the solar PV only micro-grid, it has the highest NPC compared to the other cases mainly due to the high initial cost. On the contrary, the hybrid configurations in case 3 and case 4 have much lower NPC than the other two. The PV with diesel micro-grid configuration (i.e. case 3) offers least initial investment along with moderate CO_2 emission of 1395.70 lb/MWh. According to final "Carbon Pollution Standard for New Power Plants", Environmental Protection Agency (EPA) has confirmed a limit of the emission of CO_2 gas for renewable and fuel-based power plants [18]. For renewable power plants the limit is no more than 1000 pounds (lbs) of CO_2 emission per MWh of electricity produced, whereas for fuel-based power plants, the restriction is within 1400 lbs/MWh [16]. By considering this fact, case 3 ensures CO_2 emission to be within this limit. Though case 4 offers the least cost of energy ($0.157) among the four cases, its CO_2 emission profile (1542.31 lb. /MWh) is quite above the aforementioned boundary. Furthermore, in terms of excess electricity case 4 has also been proved to be lagged behind comparatively, making it a less suitable system to prefer. On the contrary, case 3 produces the second highest excess electricity of 4142 KWh/year when compared to the other cases and has a higher PV penetration rate of 44.9%. Although case 2 ensures the highest excess electricity among these four, its high NPC, initial cost as well as cost of energy has made it less appropriate.

TABLE III. SUMMARIZED RESULTS OBTAINED BY HOMER

Item	Case 1	Case 2	Case 3	Case 4
Initial Cost($)	3.30M	2.21M	825625	850125
Cost of Energy ($)	0.216	0.203	0.157	0.153
NPC($)	5.11M	5.39M	3.62M	3.63M
CO_2 Emission (lb. / MWh)	0	0	1395.70	1542.31
Excess Electricity (kWh/year)	0	5888	4142	13.30
PV Penetration	8.79%	8.79%	44.9%	8.99%

For the optimization of the system, different types of system losses must be included in the analysis. A number of sources such as reflection, shading, soiling, irradiance, inverter, clipping etc. are mainly responsible for the losses. Fig. 7 clearly depict the losses in a pie chart. For all the cases, temperature rise results in most of the system losses. The other sources like AC system, reflection, and converter account for moderate losses. As it is shown in the figures, for case 1 and case 2, the collective loss is 31% [see Fig. 7(a)]. On the other hand, for case 3 and case 4, these losses account for 30.1% [see Fig. 7(b)].
By considering all above-mentioned fact, it can be clearly depicted that PV-diesel based micro-grid system (Case 3) offers the most balanced profile out of this four and has been proposed in this paper as the most suitable system to be adopted.

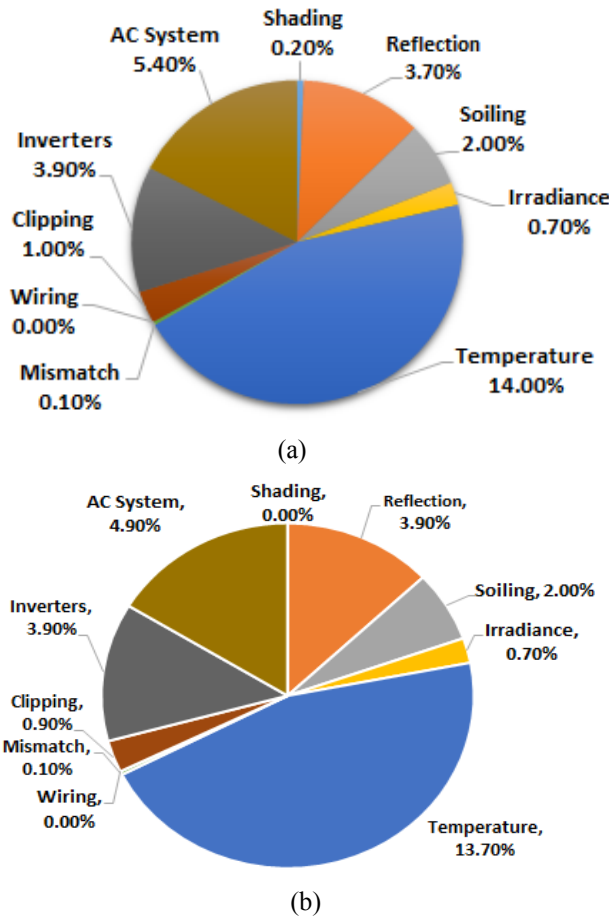


Fig. 7. Sources of different system losses. (a) For case 1 and case 2, (b) for case 3 and case 4.

VI. Conclusion

In this paper, we have systematically designed four combinations of HRESs for successfully meeting the electrical energy demand of a sophisticated load profiling area such as KUET. The combinations have been designed using the existing grid supply, solar micro-grid units, diesel-electric conversion system (i.e. generator), and storage battery system to optimize and find out a suitable hybrid system for KUET. The combinations have been entitled with case numbers and these include solar PV only with storage system (case 1); PV with storage and grid system (case 2); PV with diesel generator system (case 3); and PV with grid and diesel generator system (case 4). Simulations have been carried out for the aforementioned cases to find out the suitable and optimized combination using HOMER and HELIOSCOPE software. Parameters such as NPC, per unit cost of energy, CO_2 emission, initial cost etc. have been considered for the choice of suitable HRES. It was found that PV-diesel based micro-grid system i.e. case 3, proved to bet the most suitable choice having comparatively lower NPC ($3.62M), lower initial cost ($0.83M), lower system losses, moderate CO_2 emission along with better excess electricity profile (4142kWh/year). Additionally, the real solar irradiance data has been taken into account and most effective and cost-efficient PV array-lay out have been proposed. The protocol proposed by this study can also be applicable to areas or institutions having similar kind of load profile.

***Abstract*—Fabrication of Zinc Selenide (ZnSe) thin film having different thickness has been performed on glass substrate using thermal vacuum evaporation technique by evaporating ZnSe powder and is further characterized by X-ray diffractometer (XRD) and UV-VIS-NIR spectrophotometer. XRD patterns revealed that ZnSe thin film has face centered cubic (fcc) structure with variable miller indices at maximum X-ray intensity as the thickness changes. Substrate temperature is fixed at 290°C and all films are annealed for 60 minutes at 300°C. We have got peak value of intensity in XRD patterns which drops as the thickness of ZnSe thin film reduces. Optical properties like transmittance, refractive index, energy bandgap and reflectance have also been extracted in both simulation and experiment and found promising results. Transmittance in near-infrared region for all the films are greater than 63 % in simulation and fewer less in experiment, variable reflectance of (7-31) %, optical bandgap from 2.44 eV to 2.64 eV and fluctuation in refractive index from 2.31 to 2.70 as the film thickness changes. Optical bandgap goes wider for higher thickness films and gets lower as the film thickness decreases.**

Keywords—ZnSe thin film, thermal vacuum evaporation, X-ray diffraction, UV-VIS-NIR spectrophotometer, transmittance

I. INTRODUCTION

Thin film refers to a layer having infinitesimal physical thickness and which is formed by depositing a simple or compound materials. This thin film technology has wider applications in optoelectronic devices like LED, transistor, solar cell and storage [1].

As a compound semiconductor, Zinc Selenide (ZnSe) has intrinsic and wide bandgap properties which is comprised of group IIB element Zinc (Zn) and group VIA element Selenium (Se). Energy-momentum (E-k) diagram of Zinc Selenide (ZnSe) shows that maximum of valence band aligns with the minimum of conduction which makes ZnSe as a direct bandgap semiconductor [2].

Researchers had performed many researches on thin film due to its potential applications particularly in the field of thin film solar cells, large area electronic devices like detection of radiator, LED, field effect transistor, non-linear integrated optical devices and LASER heterostructure to improve the performance of these devices.

These works are: J. Wang and J.B. Neaton studied the effect of thickness dependent magnetism to the polarization of its lattice parameters preformed on heterostructure $BiFeO_3$ multiferroic epitaxial thin film [3]. Another investigation was done by U. Helmersson and PO Kall towards the optical behavior of TiO_2 thin films spin coated on Si substrate which were annealed in air at different temperatures and they found a homogenous and carbon free TiO_2 films with high refractive index profile [4]. Again M.W.J. Prins and R.M. Wolf discovered the consequence of transparent oxidic thin films to the operation of field effect transistor and obtained an intrinsic memory function because of these films of ferroelectric insulator [5].

Like others, H.H. Gullu and M. Parlak had scrutinized the effect of post annealing process of Zinc Selenide (ZnSe) thin film under Nitrogen atmosphere and got the deposited films nearly stoichiometric with increase in Zn and decrease in Se contents [6]. Partial similarity of our proposed work had been performed by SJ Ikhmayies and RN Ahmed on fabrication and characterization of CdTe thin film deposited by vacuum evaporation at ambient temperature and they found CdTe thin film possessing polycrystalline Zinc Blend structure also with uniform lattice structure [7]. These shortly described works were on different thin films and their properties at different external phenomena like annealing temperature, fabrication techniques and magnetic effects.

Again, compound semiconductor such as Cadmium Sulfide (CdS) [8], Cadmium Selenide (CdSe) [9] have lower transmittance and also because of their surface roughness, these two materials are not so much effective in several applications. In our research, we have thoroughly studied the response of ZnSe thin film at several thicknesses. We have found relatively higher transmittance, small bandgap and less reflectance for the ZnSe thin films having lower thickness and vice-versa.

II. EXPERIMENTAL DETAILS

Zinc Selenide (ZnSe) thin film has been fabricated by thermal vacuum evaporation technique evaporating 99.99 % pure ZnSe powder. In this evaporator, Molybdenum (Mo) boat is used as evaporation source and a glass substrate placed directly above this source. This glass substrate is polished by acetone solution and dried in sample drier.

Evaporating ZnSe powder in the vacuum chamber beyond its boiling point and fixing chamber pressure at 2×10^(-5) torr, a thin layer of ZnSe is deposited on the glass substrate. Thickness is monitored by a crystal sensor which is already connected to a digital monitoring system. During this fabrication process, substrate temperature is fixed at 290°C and after this fabrication, ZnSe films have been annealed for 60 minutes at 300°C. Using thickness monitor, we have fabricated five types of ZnSe thin films having various thickness (90 nm, 70 nm, 50 nm, 40 nm and 30 nm) by this vacuum evaporation technique and this whole fabrication process is depicted below in “Fig. 1,”.

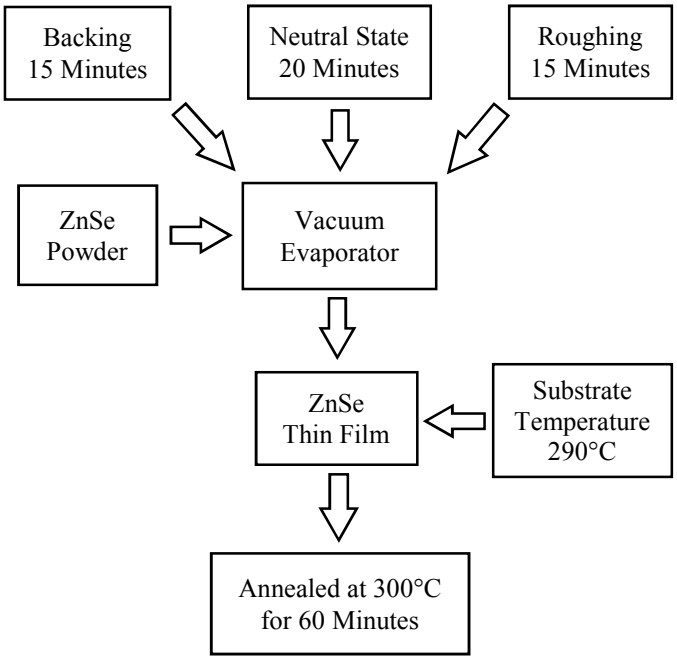

Fig. 1. Block diagram of ZnSe thin film deposition by vacuum evaporation technique.

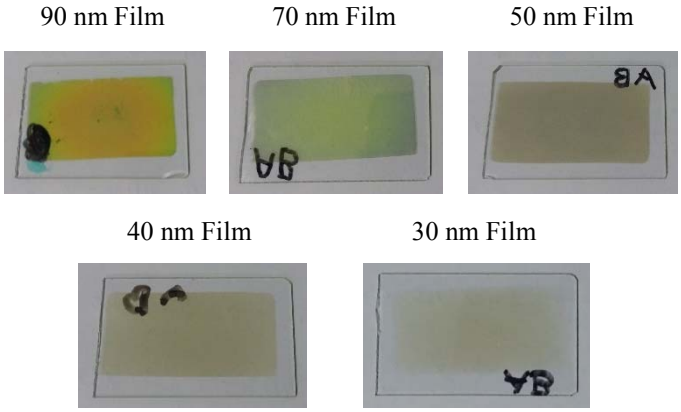

Fig. 2. Deposited ZnSe thin films on glass substrate at different thickness.

Deposited ZnSe thin films are shown in "Fig. 2", from which we can observe that as the film thickness reduces, corresponding visual intensity of film on the glass substrate decreases. That's for 90 nm film, visual intensity on glass substrate is maximum and for 30 nm film it is minimum.

III. RESULTS & DISCUSSION

After deposition, we have studied the structural and optical characteristics of five types of ZnSe thin films. Structural characterization is performed by X-ray diffractometer and UV-VIS-NIR spectrophotometer is utilized for optical characterization.

A. Structural Characterization

On the basis of X-ray diffraction principle, diffractometer operates for observing materials lattice structures. Here we have used this X-ray diffractometer to perform structural characterization of our developed films and to realize the effect

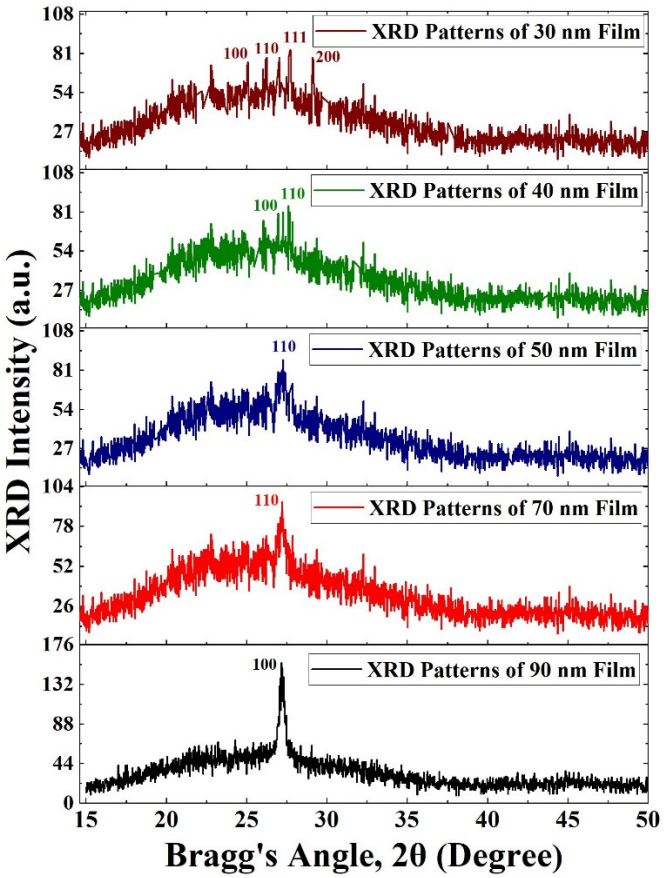

Fig. 3. X-ray diffraction patterns ZnSe thin films.

of thickness on ZnSe thin films. "Fig. 3", shows XRD pattern for all the five types of ZnSe thin films from which we can notice that ZnSe films with 90 nm thickness has maximum XRD intensity. As the film thickness decreases, maximum XRD intensity gets lower with different Bragg's angles.

90 nm ZnSe thin film has maximum XRD intensity of 156 a.u. (Arbitrary Units) at Bragg's angle 2Θ = 27.17° for 100 plane, for 70 nm film it is 94 a.u. at 2Θ = 27.49° for 110 plane. Again, 50 nm ZnSe film has maximum XRD intensity of 88 a.u. at 2Θ = 27.61° for 110 plane and which is 81 a.u. at 27.60° Bragg's angle for 40 nm film with two separate planes 100 and 110. At last, 30 nm ZnSe film shows maximum XRD intensity of 77 a.u. at Bragg's angle 2Θ = 27.68° consisting of four types of planes: 100, 110, 111 and 200.

These XRD data provide us the atomic configuration of these 5 films that ZnSe thin films having higher thickness possesses more stacked or immobile electrons in lattice because X-ray photons only interact with stacked electrons and reflected back to detector placed in the diffractometer. Using these XRD patterns we have calculated plane spacing, $d_{spacing}$ = 3.29 Å (Angstrom) which is almost same for all the five films and lattice constant, a = 5.6113 Å. For convenience, a unit cell structure of our developed ZnSe thin film is presented in "Fig. 4". From this unit cell structure, we can clearly identify that our fabricated ZnSe thin film has face centered cubic (fcc) structure.

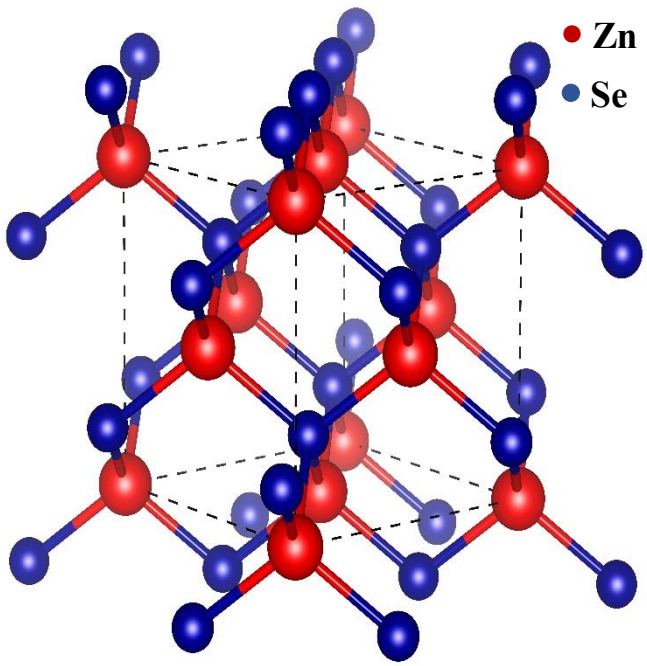

Fig. 4. Unit cell structure of ZnSe thin film.

B. *Optical Characterization*

Variable thickness of ZnSe thin film influences it's optical parameters like transmittance, bandgap, refractive index and reflectance. These optical properties are practically measured by UV-VIS-Near-infrared spectrophotometer and also simulated by Essential Macleod. First of all, lets discuss about both simulated and experimental transmittance of ZnSe which is graphically shown in "Fig. 5", and "Fig. 6", respectively. From "Fig. 5", we can notice that all the films have almost linear upward tendency of transmittance in near-infrared region and small fluctuation in visible region for higher thickness films.

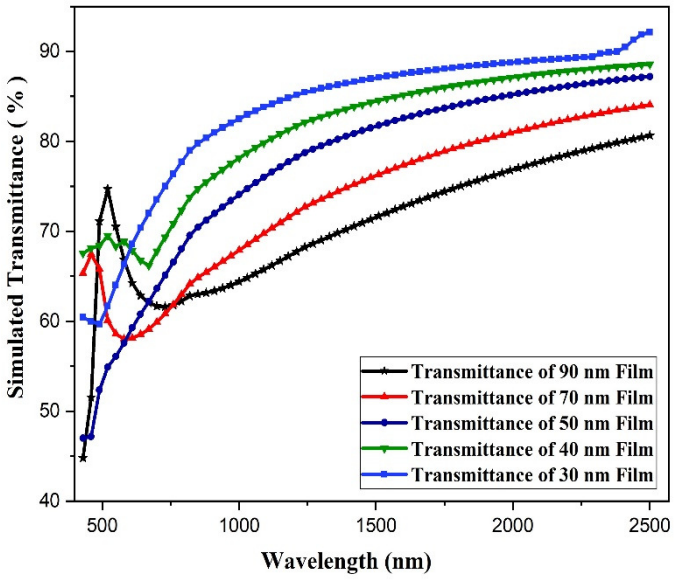

Fig. 5. Simulated transmittance of ZnSe thin films.

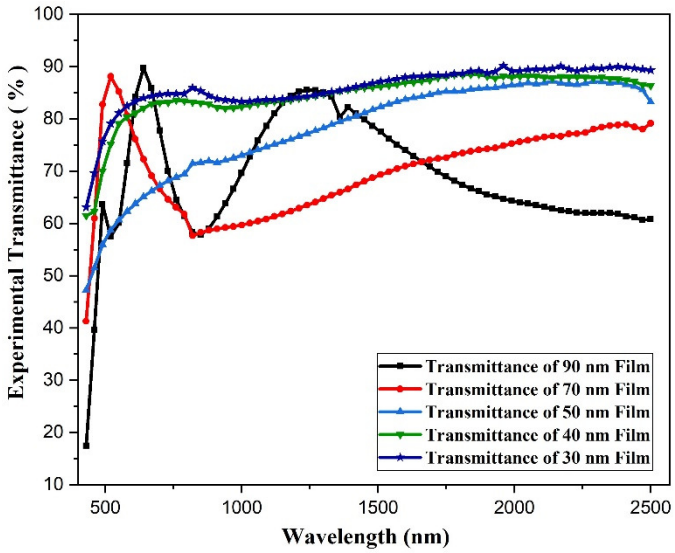

Fig. 6. Experimental transmittance of ZnSe thin films.

Another important factor we can notice from "Fig. 5", that as the film thickness decreases, corresponding transmittance increases which is maximum of 93% for 30 nm film and minimum for 90 nm film at a certain wavelength. "Fig. 6", shows practical transmittance of ZnSe thin film where 90 nm and 70 nm films have small variations in near-infrared region.

Higher thickness films have larger XRD intensity i.e. greater number of stacked electrons than free electrons. That's why these films have lower electrons in conduction band than valence band to conduct electricity.

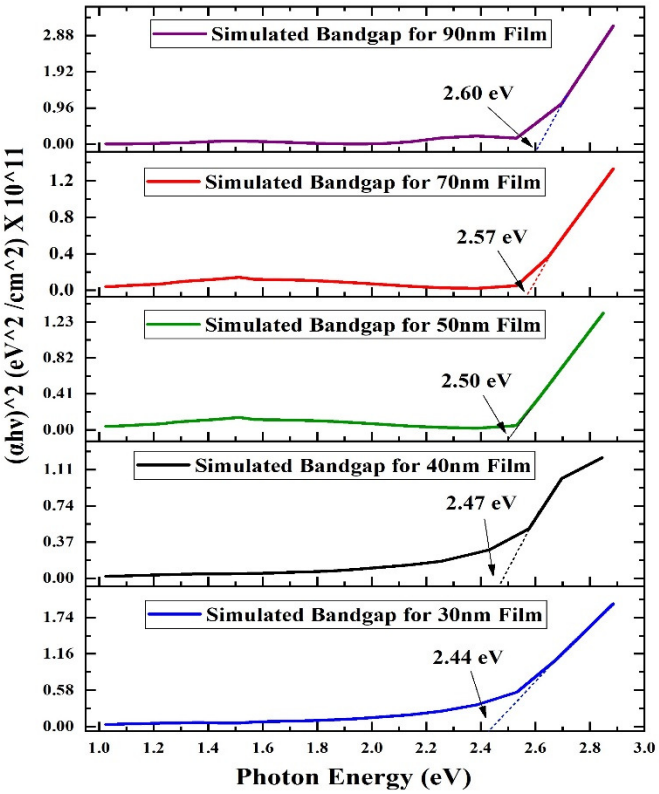

Fig. 7. Bandgap comparison of ZnSe thin films by simulation.

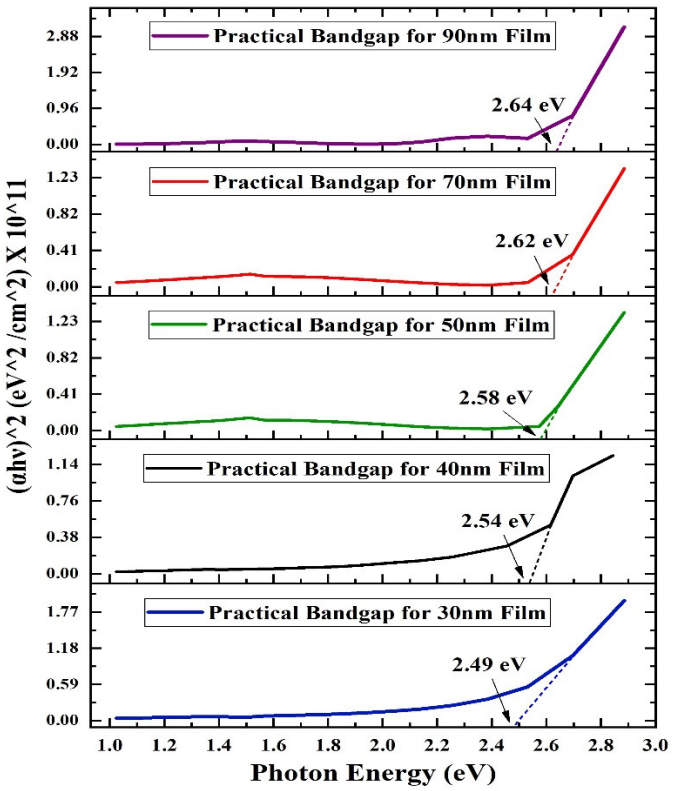

Fig. 8. Experimentally measured bandgap of ZnSe thin films.

This shortage of electrons in conduction band makes its optical bandgap wider. So ZnSe thin films with higher thickness have wider optical bandgap than films with lower thickness. Bandgap comparison for five films by both simulation and experiment is shown in "Fig. 7", and "Fig. 8", respectively and also in tabular form in "TABLE I".

Thickness also influences reflectance in such a way that for higher thickness films it is larger and for lower thickness films it gets lesser which is just opposite of transmittance. Due to the majority of stacked electrons in 90 nm film, most of the incoming photons in spectrophotometer is reflected by these stacked electrons. For this, 90 nm film has relatively the highest reflectance and 30 nm film has the lowest reflectance in the whole near-infrared region. Simulation as well as practical results of reflectance among the five ZnSe thin films are graphically shown in "Fig. 9", and "Fig. 10", respectively. Though simulation data provides smooth behavior, practical reflectance shows fluctuation for higher thickness films due to some experimental leakages.

TABLE I. OPTICAL BANDGAP FOR ALL THE FILMS

ZnSe Thin Film	Simulation Bandgap	Practical Bandgap
90 nm	2.60 eV	2.64 eV
70 nm	2.57 eV	2.62 eV
50 nm	2.50 eV	2.58 eV
40 nm	2.47 eV	2.54 eV
30 nm	2.44 eV	2.49 eV

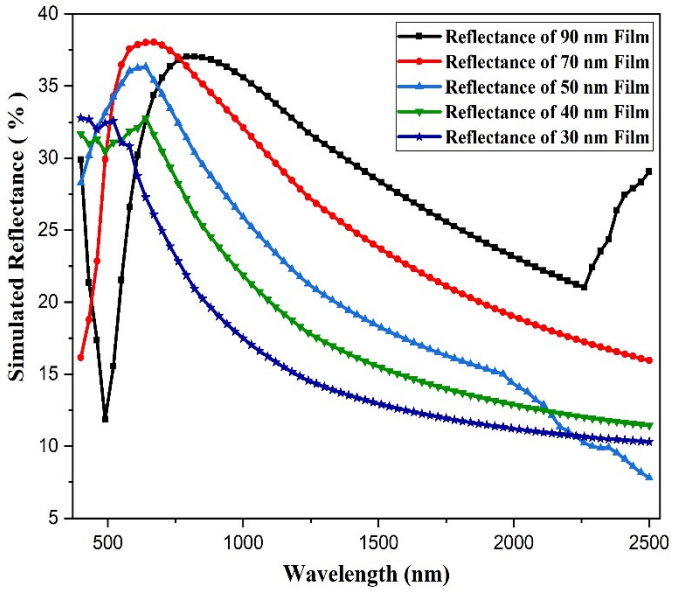

Fig. 9. Reflectance by simulation for all the five ZnSe thin films.

Photon energy of incoming light in UV-VIS-NIR spectrophotometer is related by the following equation with wavelength:

$$\text{Photon energy} = (4.135\times300) / \lambda \qquad (1)$$

Here λ is the wavelength of light in UV-VIS-NIR spectrophotometer. Refractive index (n) has been obtained from reflectance (R) and a new parameter extinction co-efficient (k). "Equation (2)" has been utilized to calculate both practical and simulation refractive index [10]:

$$\text{Refractive Index, } n = \frac{1+R}{1-R} + \sqrt{\{\frac{4R}{(1-R)^2} - k^2\}} \qquad (2)$$

For convenience, refractive index profile is shown in "Fig. 11", for both simulation and experiment. Like reflectance, refractive index increases as the film thickness increases in simulation as well as experiment.

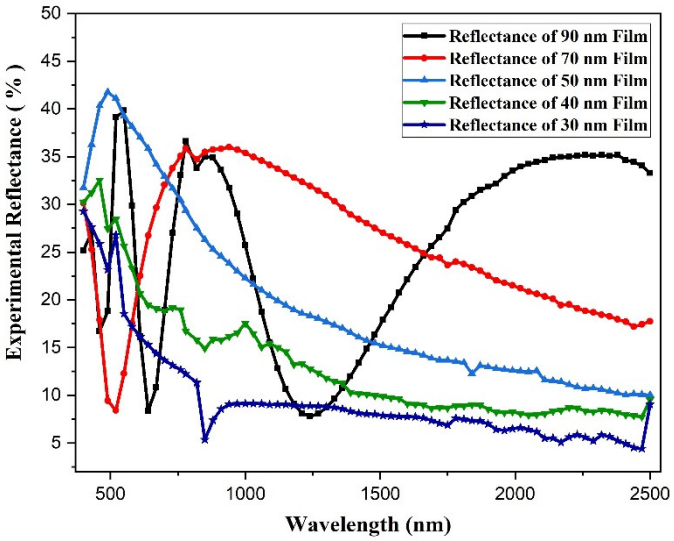

Fig. 10. Experimental reflectance for all the five ZnSe thin films.

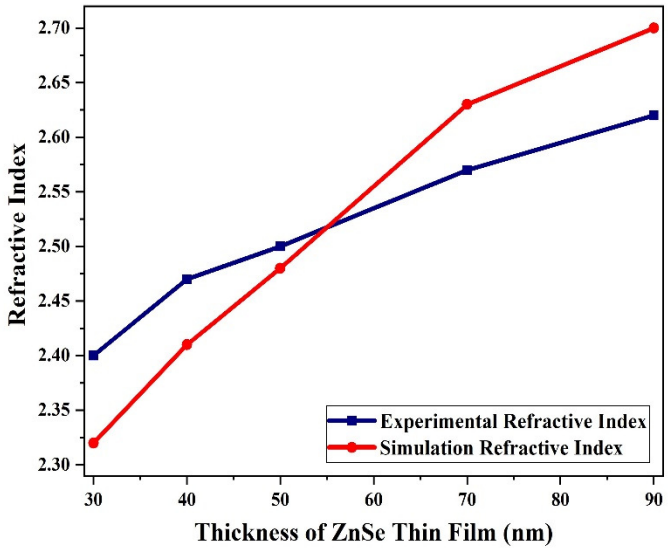

Fig. 11. Refractive index profile for all the five ZnSe thin films.

"Equation (3)" shows a way to calculate absolute dielectric constant which is composed of two parts: real and imaginary part [10]. Refractive index (n), extinction coefficient (k) and using real and imaginary part of dielectric constant we have calculated absolute dielectric constant by this complex number formula:

$$\text{Dielectric Constant (Real)} = n^2 - k^2$$

$$\text{Dielectric Constant (Imaginary)} = 2nk$$

$$\text{Absolute Dielectric Constant, } dk = \sqrt{\{(n^2 - k^2)^2 + (2nk)^2\}} \quad (3)$$

"Fig. 12", shows a graphical comparison of absolute dielectric constant in both simulation and experiment for the five ZnSe thin films. From which we have got a decreasing tendency of dielectric constant as the film thickness reduces.

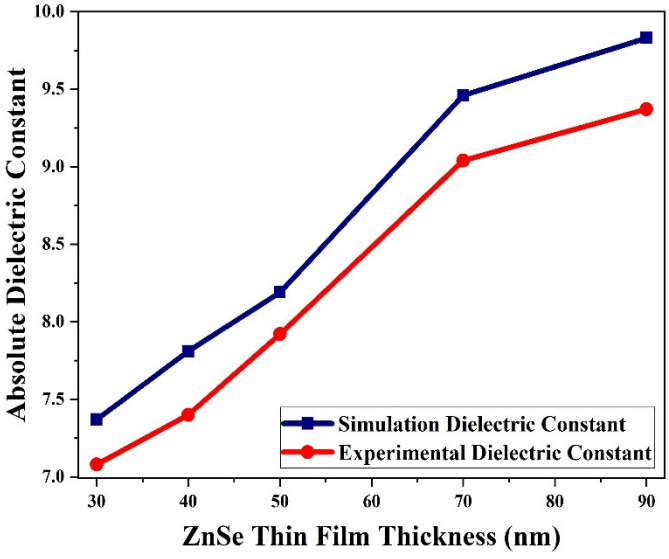

Fig. 12. Absolute dielectric constant for all the five ZnSe thin films.

IV. Conclusion

For investigating the effect of thickness in ZnSe thin film, we have performed this research and have found something promising. As the thickness of ZnSe thin film increases, optical bandgap increases creating an opportunity to apply it in wider bandgap applications such as LED, transducer and also in high electron mobility transistor (HEMT). XRD data revealed that lower thickness reduces the number of stacked electrons and turns ZnSe lattice into porous form. Again, XRD analysis and unit cell structure have proved ZnSe thin film has polycrystalline as well as face centered cubic structure. Because of this porous cubic polycrystalline structure, ZnSe thin films with lower thickness have high transmission coefficient, low reflection coefficient and reduced optical bandgap. These make lower thickness films more suitable than higher thickness films to use as a transmitting layer in several optoelectronic applications.

***Abstract* - The political and socioeconomic challenges in Somaliland have caused a lack of scaled and interconnected power infrastructure which resulted in a power shortage with power loss in transmission. The fluctuating cost of diesel fights to move away from the recovery of the post-conflict situation to a relatively rapid economic development. The reliance of the majority of the population on biomass to meet their urban and rural energy demands has depleted the forest and used crop residues, however, the use of biomass has recently decreased in urban cities. This paper presents a feasibility study of Solar Photovoltaic, wind turbine, and generators based on hybrid electric supply system to Burao Somaliland urban center (9.5259° N, 45.5346° E). This study has been carried out to show the supply of electricity to a small residential load and the target to reduce the cost of energy. Besides, a comparative study was carried out with renewable resource-based microgrid hybrid energy system compared to a current diesel-only micro-grid, hence in this case study, the best cost-effective solution is considered by using different renewable energy sources. Solar and wind potentials have been estimated from NASA surface meteorology. HOMER has been used for optimization and sensitivity analysis for the hybrid system.**

Keywords—Burao, Micro-Grid system, Renewable Energy, Optimization, HOMER, Wind Energy, PV, Biomass.

I. INTRODUCTION

The consumption of total fossil energy around the globe is 80% which contains fossil fuel energies, i.e., oil, coal, and natural gas [1]. However, the fossil energy is limited in supply, and it reduces the fossil fuel resources; thus, alternative energy to fossil energy is a crucial point of discussion as the fossil energy sources will be depleted one day compared with consumption rate [2]. Also, the fossil fuel burning is the main cause for growing the total of Greenhouse Gases (GHGs) in the atmosphere and another motive to think of alternative solution. The hybrid system and renewable energy can be of great aid in this condition for its environmental nature and eco-friendliness.

Recently, renewable energy becoming popular around all over the world to confirm the excellent development of getting or greeting the resource of the environment, e.g. sun or wind etc. through as electricity. The introduction of new technology which provides renewable energy is allowing both isolated and urban communities to increase their quality of life by finding renewable and reliable energy systems. Increasingly, Communities require to investing in off-grid Renewable energy facility systems. Burao is located in the region of Somaliland (09°31′27″N 45°32′13″E) and has a total population of 288,211 residents, and it is the second-largest city in Somaliland. The average daily solar global radiation for Burao ranges from 4.99 to 6.41 kWh/m2/day, and monthly average wind speed varies from 4.2 to 8.2 m/s [3]. The cost of generating energy from the above hybrid system was different COE US$/kWh Based on the cases). But for the diesel, the only option in the existed arrangement leveled cost of energy for Burao $1.0/kWh and sometimes less than 0.8 $ /liter. The problem of high-cost diesel has affected the production and business activities which requires affordable electricity to continue their day-to-day productions and works, in some cases their outsource operations to other countries with a lot of reasonable power facilities. Two hundred eighty-eight thousand two hundred eleven residents, it is the second-largest city in Somaliland.

The people need electricity at a cheap rate and also keep environment pollution free. The diesel based generators increase carbon dioxide in atmosphere catastrophically. But using the resources of a renewable energy does not affect environment or there is almost zero carbon dioxide emission. This paper focuses on the feasibility d analysis and economic impact assessment of microgrid renewable energy systems in Burao, Somaliland whereas the cost of electricity is high from national grid also the private grids.

The cost of energy is the lowest (USD 0.2522/kWh CEOs) of the hybrid micro-grid system. The optimum system configurations varied based on assumption of diesel pricing, but hybrid energy systems are the most economically viable solution comparing with diesel driven arrangements. Moreover, the majority of people living in rural and urban areas have no access to electricity, although the power is only available in city center and in practically totally generated by diesel imported from foreign countries [4]. The people live in the city, or urban areas are paying some of the highest prices in all over the world for a limited ($0.80 to $1.50) [5] per kilowatt hour, and sometimes the services are not reliable and there are electricity outages and its unreliable service on productivity in the developing world mostly it leads to substantial aggregate effects of economics.

II. Electrical Load Profile

In this project, the electrical load consists of residential demand and some business stores. The average load of each residence is considered to be 50 kWh/day. The characteristics of the load are estimated according to TABLE I.

TABLE I. LOAD MEASUREMENT FOR DIFFERENT FAMILIES

No. of residences	100
Peak demand	532.75[kW]
Duration of peak demand	1800-2200
Duration of low demand	0000-0004
Annual Average Load	2588[kW]

The yearly daily load profiles of 100 residences are shown in Fig. 1. The horizontal axis represents hours, and a vertical axis corresponds to the kW of consumption.

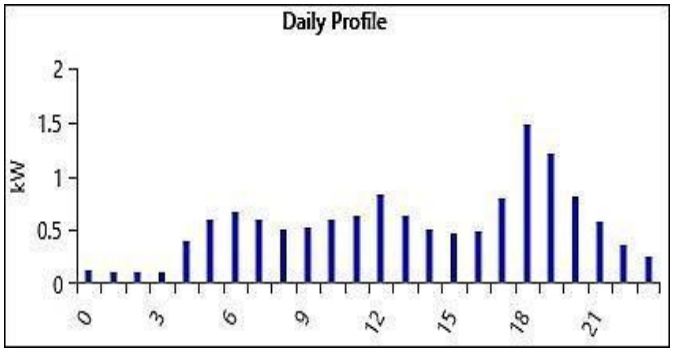

Fig. 1 The daily load profile of 100 residences.

During night the annual power consumption is high.

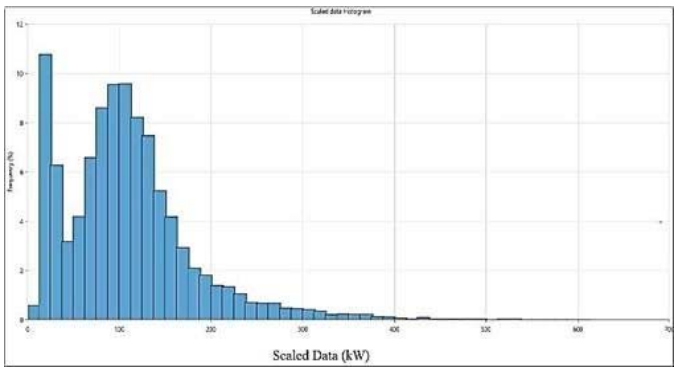

Fig. 2 Frequency histogram of annual power consumption of the 100 Residences.

III. Renewable Resources

The annual horizontal level of radiation in the area is 5.960 kWh/m^2/day [6]. In Fig 3. shows the monthly level of solar irradiation. The monthly variations of solar radiation and Clearness Index (CI) are given in TABLE II.

TABLE II. MONTHLY SOLAR RESOURCES IN BURAO

Months	Clearness Index(CI)	Solar Radiation (kWh/m^2/day)
January	0.589	5.270
February	0.631	6.060
March	0.625	6.410
April	0.587	6.170
May	0.604	6.280
June	0.616	6.300
July	0.605	6.210
August	0.611	6.350
September	0.619	6.360
October	0.580	5.660
November	0.602	5.460
December	0.574	4.990

HOMER needed numerous data of solar irradiation to calculate the solar power generated using the panel. The monthly mean solar radiation data has been taken from NASA surface meteorological department. It has monthly averaged global horizontal radiation for periodic of 20 years.

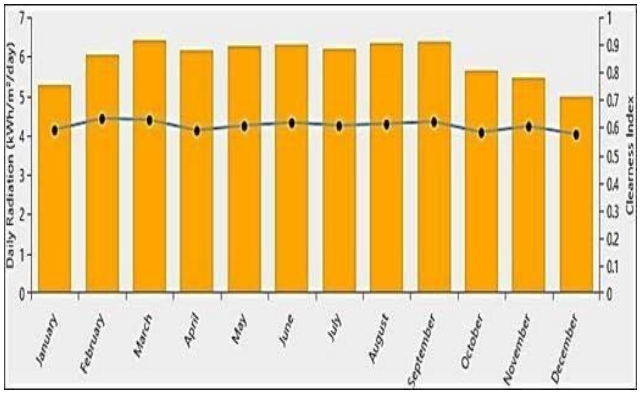

Fig. 3 Graphical presentation of solar radiation per month.

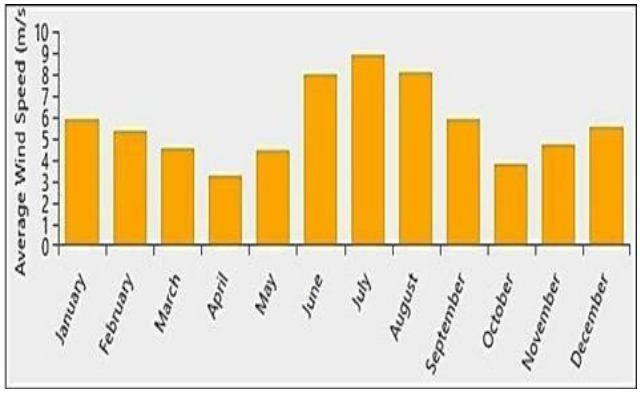

Fig. 4 Graphical presentation average wind speed per month.

The average wind velocity has considered to be 5.710 m/s annually [7]. It is observed from Fig. 4 that the wind velocity remains in the range of 5-6 m/s throughout the year. This range is very appropriate for the implementation of wind power project.

In Fig.5. demonstrates a combined hybrid system designed to fulfill electrical power demand in Burao. That is the Diesel Generator, Bio-gas generator, Wind Turbine, PV and Battery. The designed configuration has a total Net Present Cost (NPC) of $3,079,776.00 and the Cost Of Energy (COE) of $0.2522/kWh [8].

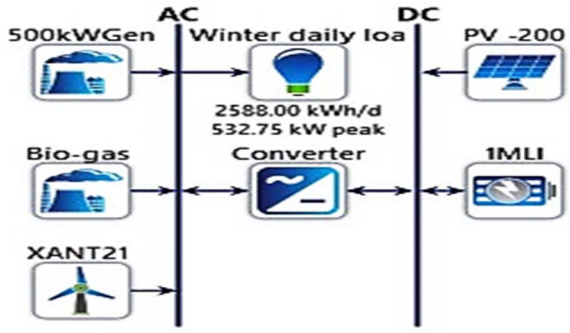

Fig. 5 Designing of hybrid energy system in Burao.

A. Photovoltaic System

To produce electrical power from solar energy a Generic flat plate Photovoltaic (PV) has incorporated in the proposed designing. 200 kW PV arrays has used that have 20.1% capacity factor that could supply around 40.2 kW. Fig.6 depicts the output power of the arrays that used in proposed model. The cost of installation for the PV array is around 1,035,000.00$ with a lifetime of 20 years. To ensure the best use of day lights the sun tracker attached with PV panels also moves on horizontal axis every day. In each year the PV modules produce around 351,778 kWh by the optimized model that is almost 32 percent of the total electrical power generation by the proposed system.

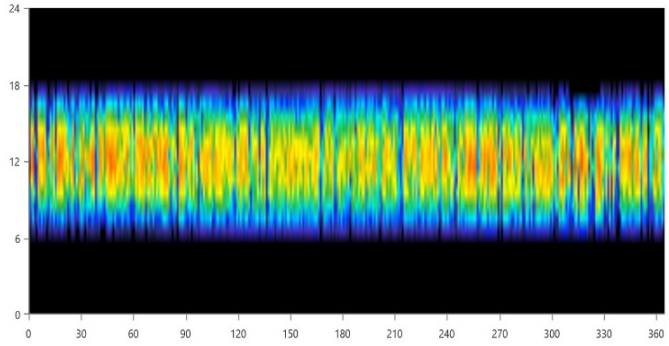

Fig. 6 Power output of generic flat plate PV

B. Wind Turbine

In this proposed hybrid model a XANT21 wind turbine has used to convert available wind energy to electrical power. Every wind turbine 200 kW rated that can supply about 44.6 kW along with 22.3% capacity factor. Twenty-five wind turbines (WT) had incorporated in proposed hybrid model considering 25 years' project lifetime. The initial installation cost is around 53,333$, and O & M cost is about 215$ per year has considered. In this optimized model, the twenty-five WT generate around 390,336 kWh annually via 6967 hours'/year operation.

C. Diesel Based Generator

To generate the electricity from the diesel generator, we have used Generic 500kW Fixed Capacity Genset with a fuel curve of intercept 7.00L/Hr. and the fuel curve slope is 0.244L/hr/kW. The capital cost of a diesel generator is $81,468.00. And the emission of a carbon dioxide is (g/L fuel) 13.566 and the lifetime hours is 15,000hrs.

D. Li-Ion Battery as a Storage

However, the renewable energy sources provide average quantity energy for an extended period, hence it must need energy storage devices to supply uninterrupted power to the customers or buyers when the resources furnish low amount of power. We have used three batteries that is a Generic 1MWh Li-Ion unit to store the energy of PV panel which at a 12V nominal voltage. Two groups separate panels have used in every string to assure 24V at each bus. The capital cost of a battery is $233,333.33, and cost of replacement for each cell is $98,997.23.

E. Converter Arrangement

The converter can be employed to convert both DC to AC or AC to DC which implies the converter serve as either rectifier nor inverter. In the design model, it is needed to convert the DC voltage supplied by the PV modules and batteries as the energy is used by Alternating Current loads. So, in this research 100kW converter has used for the conversation purpose. The capital cost or the amount required is $55,904.26 and the replacement cost for the converter is $23,718.71. This converter has considered 90% efficient for 15 years of a lifetime.

F. Biogas Generator

To produce electrical power from household and other wastage a generic biogas Genset has considered with minimum 50% load ratio. The first investment cost is 3,000$ per kW where 5$/hour Operation and Maintenance (O&M) cost has taken in consideration for 20 thousand hours' life span. Also, 5.5 MJ/ kg lower heating value of the biogas considered that contain 5.5% carbon content. The people of Somaliland depend on live stocks like Camels, Cattle, sheep, and Goats; also the second most important resource is crop farming, i.e., Sorghum and Maize which play the role of economic activities even its considerable underdeveloped potential especially the cover plants annual average produce 0.710 Tons, so it is possible to create an electric potential by using a Biogas Generator.

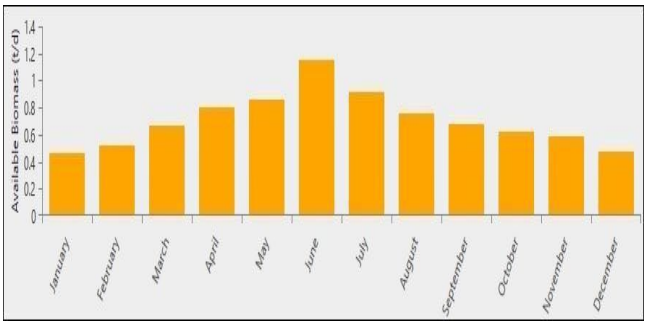

Fig. 7 Variation of Average Biomass Resources in Burao throughout the year.

The monthly biomass resource production is shown in fig.7. The highest output is found in June. At that time there are many waste plants and animals like the cover of sorghum and maize and the lowest month is January.

IV. RESULT ANALYSIS

The optimal configuration obtained from the simulation is considered as follows:

- ✓ Diesel power project 500 kW
- ✓ Solar energy project 200 kW
- ✓ Wind power generator 200 kW
- ✓ Biogas Generator 100 kW

In this project, the income obtained from electricity consumption of 100 residences gives a monthly amount of USD 0.2522$. Therefore, the system is going to collect USD $25.22 and during the 20 years USD 6052.8$. This cost is enough to cover the cost due to maintenance and operation. The summary of the values of the initial capital cost is given by Fig 10. Although the significant cost to implement the proposed hybrid model is the capital cost and it is around 1.77 million dollars. Though the installation cost seems high, during the 20 years, the total cost for O & M services are $238,842.76.

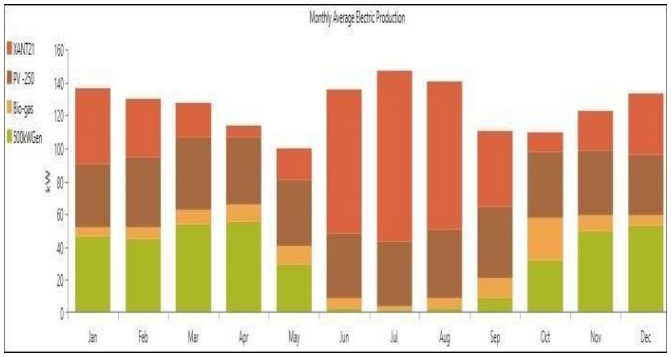

Fig. 8 Monthly average electricity production from different types of Resources.

The NPC of the project is $3,079,776.49 which is less than the rural electrification budget USD $29,368,000.00 million [9, 10]. Hence it is economically feasible. Fig. 8 depicts the average generation of electric power per month of numerous types of resources.

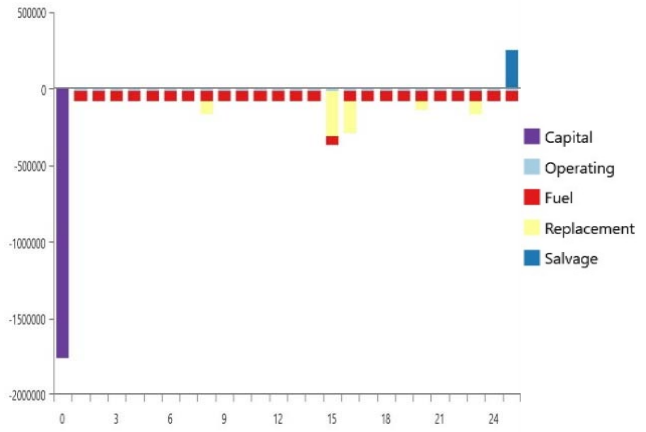

Fig. 9 Cash Flow.

V. ENVIRONMENTAL AND SOCIAL ASSESMENT

In this project environmental assessment of micro-grid is also discussed. Somaliland is a developing country that affects climate change. This is mainly due to the high reliance on fossil fuel.

A. Environmental Assessment

The use of power from renewable energy will decrease or reduce the number of gaseous pollutants in the atmosphere. Diesel fuel contains 80,658L of pure carbon. A liter of an Atomic carbon forms 3.78541gallon of carbon dioxide when oxidized with O2 considering 99% of the fuel is oxidized the amount of carbon dioxide per gallon becomes 305,322.793litre [11]. Table V the amount of carbon dioxide produced by 500kW generator if operated alone and when integrated with renewable resources. It is noticeable that the amount of carbon dioxide and carbon monoxide is reduced when the diesel generated energy is combined with Renewable Energy. Nowadays the electricity generation in Somaliland is generally done through diesel generators. However, it has one of the highest electricity rates in the northwestern Somalia; however, the source of renewable energy is the energy that is collected from renewable resources, and it has a high in solar radiation all the months or the year, and also three months are the most top resources of wind speed (June, July, and August) as we have seen in Fig. 4 [12], and the other months also it's available the resource of renewable energy. Using the diesel generator, it has a lot of effects or allots of carbon dioxide or emission, but renewable energy sources have no impact of the environment problem, the comparison of electrical production in renewable energy sources and also diesel generator are the following in TABLE III.

TABLE III. ELECTRICAL POWER GENERATION

Production	kWh/yr	%
Generic Flat Plate PV	351,778	32.0
Generator 500kW	274,309	24.9
Wind turbine	390,336	35.5
Biogas Generator	84,080	7.64
Total	1,100,503	100

There is a slight difference between the production of renewable energy and the diesel generator, although we are using a considerable difference capacity between the diesel generator and solar or wind [13]. Here we understood the benefits of renewable energy are higher than the diesel generator. TABLE VI shows that the integrated renewable energy systems will reduce CO_2, CO, SO_2, and NO_2 more than four times and five times respectively than existing diesel-based generator systems.

TABLE VI. COMPARISON OF EMISSIONS: DIESEL VS INTEGRATED RENEWABLE ENERGY

Production	Alone	Integrated
Gal/Hr	227.124	227.124
Hrs/Yr	3100	2124
CO_2	967,333kg/yr.	211,551 kg/yr.
CO	5,004 kg/yr.	1095kg/yr.
Unburned Hydrocarbons	266kg/yr.	58.1kg/yr.
Particulate Matter	42.8kg/yr.	9.36kg/yr.
Sulfur dioxide	2,365kg/yr.	517kg/yr.
Nitrogen Oxides	959 kg/yr.	210kg/yr.

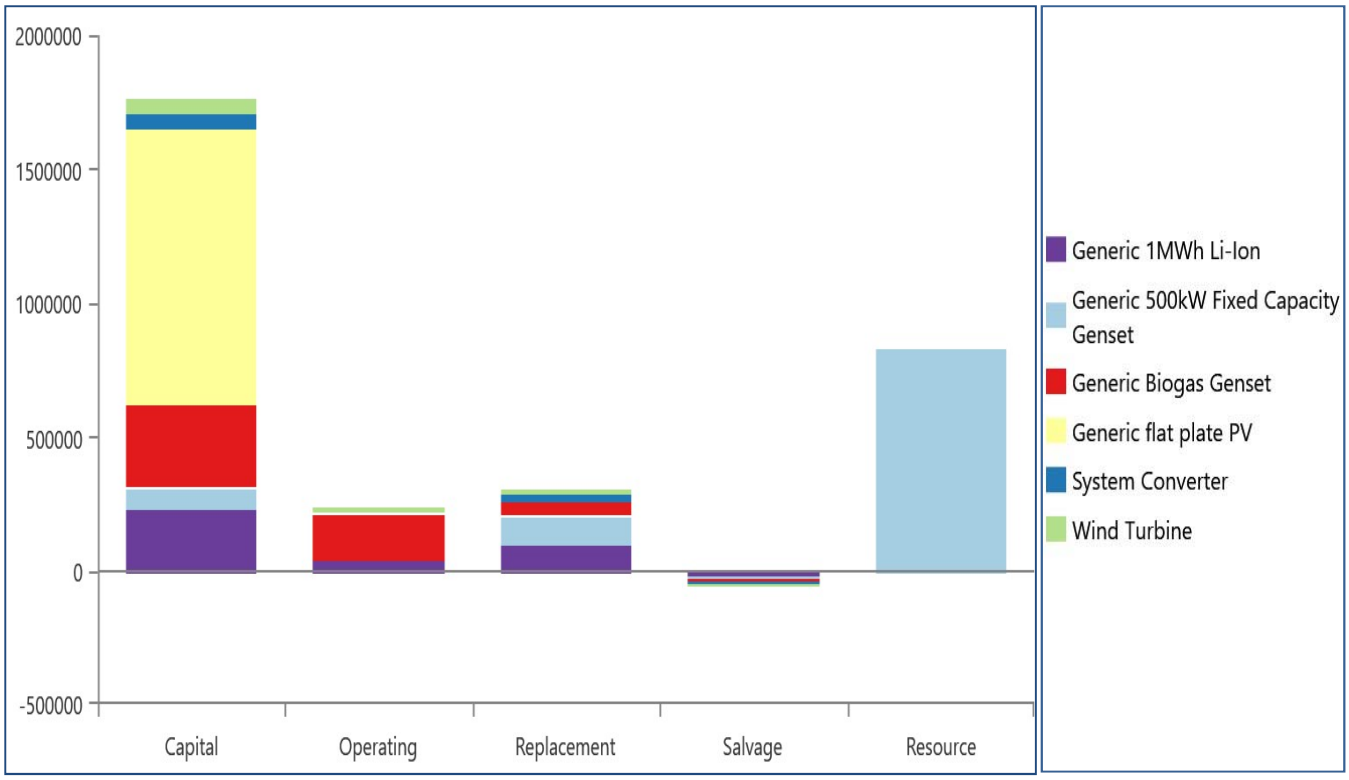

Fig. 10 Summary of cost of the proposed designed model for different components.

TABLE V: COST SUMMARY DESIGNED SYSTEM FOR DIFFERENT COMPONENT

Name	Capital	Operating	Replacement	Salvage	Resource	Total
Generic 1MWh Li-Ion	$233,333	$43,092	$98,997	-$18,632	$0.00	$356,790
Generic 500kW Fixed Capacity Genset	$81,468	$5,070	$108,541	-$14,279	$834,170	$1.01M
Generic Biogas Genset	$300,000	$164,826	$50,994	-$12,165	$0.00	$503,655
Generic flat plate PV	$1.04M	$0.00	$0.00	$0.00	$0.00	$1.04M
System Converter	$55,904	$0.00	$23,719	-$4,464	$0.00	$75,159
Wind Turbine	$60,000	$25,855	$19,128	-$10,780	$0.00	$94,203
System	$1.77M	$238,843	$301,379	-$60,321	$834,170	$3.08M

In table V, it denotes the summary of cost for the optimized hybrid model by various components. The main cost to implement the proposed model is capital cost which is about $1.77 million. But the amount of a total system is 3.08 million USD.

B. Social Assessment

When microgrid installed in rural areas, new job opportunities will be created. Job openings will not only be in the design and installation phase, but also experts will be required for the operation and maintenance of microgrid. It will also help to develop the livelihood of the local lower-middle-class families by creating jobs for them [14]. Reliable and affordable supply of electricity will help to boost up the local economy. In our time, electric infrastructure is the backbone of the economy. Initially, the business and industries will not operate due to the lack of supply and diesel generator is not economically efficient but by installing microgrid the business hours are also increased and hence produced capacity increases.

VI. CONCLUSION

In this study, we discussed the impact of the microgrid on the environmental and socioeconomics of Burao Somaliland. The result of the simulation obtained from HOMER shows that it is feasible to deploy microgrid by integrating conventional diesel generator with renewable resources. The introduction of the microgrid in rural areas will help to boost the local economy and also it will have a positive impact on the environment. The simulation shows that the cost of energy is meager and affordable by poor people. The amount of pollutants released in the atmosphere is reduced by encouraging renewable energy resources. The proposed system is very eco-friendly by reducing GHG emission at a remarkable level.

Lightning Effect on a Large-Scale Solar Power Plant with Protection System

Mohammad Riajul Karim* and Md. Raju Ahmed
Department of Electrical & Electronic Engineering
Dhaka University of Engineering and Technology (DUET)
*Email: riaz4623@gmail.com

***Abstract*—While lighting is a potential natural threat to a solar power generation plants and their electrical equipment, conventional protection against it has still remained inadequate. A possible reason is that the effect of lighting is not completely realized with the requirements and design considerations of the protection system. Unlike the other installations and systems susceptible to lighting, the solar panels extended over the large and open area are usually more exposed to the lightning strike. Lightning creates a strong electromagnetic field and induces extremely high voltage for a moment that can damage the photovoltaic (PV) panels, DC lines, inverter, underline cables and other equipment. In support of safety-protection, in this paper, we have modeled a Lightning Protection System (LPS) and investigate the lightning effect on a large-scale solar power plant with the proposed LPS. Additionally, we have analyzed the variations in the electromagnetic field, induced voltage and current due to lightning in the plant with the LPS using Virtual Surge Test Lab (VSTL) simulation. The presented analysis and recommendations would help to determine fundamental requirements and design considerations of an appropriate LPS for a large scale solar power plant.**

***Index Terms*—Electromagnetic field; lightning Induced voltage; Protection system; PV panels; FDTD method; VSTL.**

I. Introduction

As a potential green energy source, the solar power plants are rapidly growing all over the world [1]–[3]. To support the global clean energy revolution and to mitigate the lack of fossil fuel, Bangladesh has also taken initiatives for establishing solar power plants in the government and private sectors [4]. Many mini-grid solar power plants have already been running in Bangladesh such as the plants at St Martin, Kutubdia Island, Sandhip, Vola, Bangladesh Bank Motijil and Manikgong. Several large scale solar power plants are also planned to establish towards the government's target of producing 10% of total power demand with renewable energy by 2020 [5]. With this rapid expansion of the plants, their safety against the increasing natural calamities like lightning has posed an additional challenge.

A Lightning Protection System (LPS) is usually considered adequate for the protection of a solar power plant against the lightning effect. However, unlike other installations and systems susceptible to lighting, the solar panels extended over the large and open area are usually more exposed to the lightning attack. So, the requirement of an LPS for a solar power plant should reasonably be different from that of the other installations and systems. This gap in design considerations of an LPS may potentially leave it to be inadequate for a solar power plant. One obvious reason for employing such an inadequate LPS is that the effect of lighting is not completely realized for a solar power plant.

To determine the requirements for developing an effective and adequate LPS for the solar power plants, study of the lightning effect on the solar power plant is essentially required. Conventional LPSs, which are usually considered for the mini-grid solar systems in Bangladesh, include only a few (*e.g.*, one or two) air-termination rods with direct earthing from inverter to ground. Such LPSs will presumably not protect the whole PV plant against lightning. This is because, the solar power plant can be affected by both the direct and indirect strike of lightning. Both the direct and indirect lightning creates a strong electromagnetic field and induces high voltage which can damage the photovoltaic (PV) panels, PV generator, DC lines, inverter, underline cables and other equipment of the solar power plants [6]. Those effects of lightning can be more critical for the safety of a large scale solar power plant.

Most of the lightning effect analyses in the literature capture the power lines [7], [8], microwave relay station [9], [10], wind turbine [11], [12], small scale solar panels [6], [13]–[16]. However, no or a little effort can be tracked on the analysis of medium and large scale solar power plant that occupies a relatively larger open area. Induced voltage on DC cable due to the lightning electromagnetic interference is studied in [14] to demonstrate that the induced voltage can also damage the underground DC lines. Using electromagnetic analysis, Rabbani *et al*. [15] showed that the induced voltage also depends on the depth of the pipeline, strike location, soil resistivity and permittivity. The above analyses although identified essential factors and their effect on the induced voltage, they mostly considered a small scale solar power plant.

Additionally, Charalambous *et al*. [16] studied the effect of lightning on a solar power plant with a protection system. Their proposed models were analyzed for the current flow and energy dissipation through the earth-terminal. Although an isolated and non-isolated protection systems were employed, induced voltage due to induction was not considered in their model. In our earlier work [17], we studied lightning effect on a large-scale solar power plant to analyze the electromagnetic field, induced voltage and current due to lightning in the plant using the Virtual Surge Test Lab (VSTL) simulation.

In this paper, we model an LPS and investigate the lightning effect on a large-scale solar power plant with the proposed

LPS. Unlike our earlier work in [17], the current in the DC lines of PV plants is calculated using time domain simulation process in presence of our proposed LPS. Additionally, we have analyzed the variations in the electromagnetic field, induced voltage and current due to lightning in the plant with the proposed LPS using VSTL. With simulation and analysis, we conclusively demonstrate the lightning effect on the electromagnetic induction, induced voltage and current in a large-scale solar power plant in presence of the proposed LPS.

The rest of this paper is structured as follows. Modeling of a large scale solar power plant and its LPS is presented in Sec. II. Simulation results and analysis with initial recommendations for an appropriate LPS of a solar power plant are presented in Sec. III. Concluding remarks are noted in Sec. IV.

II. Proposed Model for the LPS Analysis

In this section, we present the specifications of a large scale solar power plant, a lightning protection system (LPS) for it, and their models using Virtual Surge Test Lab (VSTL) to analyze the variation in lightning effect on the plant in presence of LPS. Before we describe those specifications and simulation models, we introduce below the working principle of VSTL.

There are many methods of analyzing the electromagnetic induction and induced voltage in a solar power plant. Virtual surge test lab (VSTL) is one of the most suitable methods to analyze the electromagnetic field, induced voltage and current, due to lightning on a large-scale solar power plant. VSTL is developed based on FDTD [18] method by the Central research institute of Electric power industry, is simulation software to analyze the lightning current.

Lightning stroke channel having propagation velocity of return stroke is one-third of the speed of light and represented by engineering model built in VSTL [19]. The current waveform of that model is evaluated in [20], and the analytical expression is given in Eq. (1).

$$i(0,t) = \frac{i_{\max}}{k} \times \frac{\left(t/T_1\right)^n}{1+\left(t/T_1\right)^n} \times e^{-t/T_2} \tag{1}$$

Here, $i_{\max}$ is the peak current, T_1 is the front time-constant, k is the correction factor for the peak current, T_2 is the tail time-constant, and n is an exponential factor. The value of n varies from 4 to 10, T_1 varies from 0.25us to 10 us, and T_2 varies from 100us to 350us. These values are considered with i_{max}=100KA, $k = 1$ $n = 8$, T_1= .25us/1us, and T_2= 100us. The lightning current shape used for our model is shown in Fig. 1.

A. Solar Power Plant Specifications

We considered 150*KW* solar power plant for our analysis. A general layout of PV panels is illustrated in Fig. 2. A standard PV panel has 250 *watt* output power. Therefore, for the generation of 150*KW* solar power, 600 panels are required as a minimum. Single solar panel occupies an area of $1.5m \times 1m$. Therefore, a $50m$ long and $4m$ width frame can hold 100 PVs in two sub-rows, which occupy $50 \times 4 = 200m^2$.

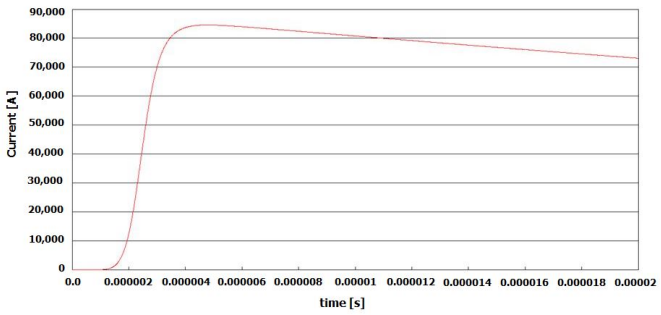

Fig. 1. The injected lightning current (*LC*) waveform used for the VSTL model

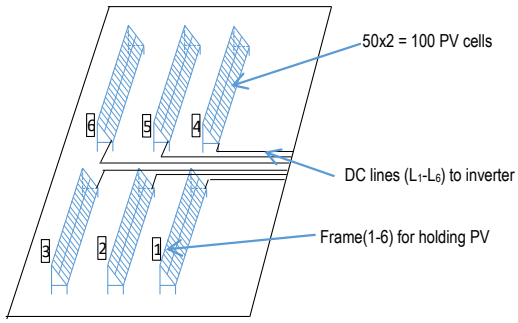

Fig. 2. The layout of the PV panels of 150*KW* solar power plant

The gap between the two rows is $6m$, and the gap between the two columns is $10m$. The required total area is thus $140m \times 45m = 6300m^2$. The PV panels are placed on the fixed inclination frame. The height at the front of a frame is $2m$ from the ground, and at the back side, the height of the frame is $4m$ from the ground. All the DC lines are placed $4m$ above the ground, and DC-lines of each group are combined and lead to the inverter.

B. Our Proposed LPS for the Solar Power Plant

The design of our proposed LPS for a large scale PV system mainly depends on the appropriate risk assessment, type of plant, location of the plant. In this paper, we have emphasized on external LPS, which is consist of air-termination system and earth-termination system. The layout of the proposed LPS is illustrated in Fig. 3. Air-termination rods of $10m$ height is located at the fixed $1m$ back of each PV Supporting frame. For reducing the cast, we can fix the air-termination rod with PV frame with *L*-type clump and insulator to avoid the direct contact with the frame. These air-termination rods will then be connected with the earth-termination system. In this proposed model, three air-termination rods are planned behind each PV frame, which is $50m$ long as such it will offer a necessary protection angle and protect the PV panels from the direct strike of lightning. All the air-termination rods are interconnected through earth-electrodes, which is made of copper wire and laid $1m$ under the ground. In the proposed LPS, the air-termination system intercepts between the lightning and the

physical parts of the plant. Air-termination system embraces the down-conductors to discharge the lightning current in the general mass of earth through the earth-termination system.

C. VSTL Simulation Model

The VSTL simulation models have been developed for the $150KW$ solar power plant without any LPS and with the proposed LPS as showed in Fig. 2 and Fig. 3, respectively. The solar panels were considered as made of thin wire [21]. In the VSTL model dimension of the X, Y and Z are taken $140m$, $45m$ and $30m$, respectively. The earth of size $10m$ is considered in the Z axis. The ground resistance is considered to be 100Ω. The PV panels are considered to be placed on the $4m \times 50m$ metallic frame. Frames are plotted by thin wire as suggested in [21]. To accommodate 600 PV panels , six sets of frames are required. These 6 frames are placed in two columns, and each column holds 3-row frames. The front height of the frame is $2m$, and back height is $3m$. The pillar of the frame is $1m$ underground. The DC lines from each frame array combine together and lead towards the inverter as such the six pairs of wire from the six rows lead towards the inverter. The voltages are measured from the DC lines to ground. The lightning current source is placed in a different location to see the effect of the direct strike on the ground. Additionally, a set of air-termination rods and earthing electrodes have been plotted with thin wire as illustrated in Fig. 4.

III. Results and Analysis

The direct and indirect lightning strikes have been investigated to determine their effect on the Solar Power generation with and without the proposed LPS. For different locations of the lightning strike, the induced voltages are calculated. We observed that a strong magnetic field is being created in around the lightning strike. Large voltage induces in the PV frame and DC line leading to the inverter. The induced voltage depends on some parameters such as the location of the lightning, the rate of rising of lightning current, earth-resistance, *etc*. Due to the rise of the earth-resistance, the induced voltage increases, which can be an important criterion of site selection for a solar power plant. On the other hand, due to the induction of a lightning protection system, the induced voltage reduces. This is explained below with necessary illustrations.

A. Lightning Effect on DC Lines with and without LPS

We observed that, with an LPS, the induced voltages is much reduced. Fig. 5 shows that, without any earthing system, the maximum induced voltage is $1250KV$. But in case of employing an LPS, the voltage reduces to $650KV$ as illustrated in Fig. 6. We also observed that the induced voltage quickly dies to zero in case of LPS. High voltage for longer time produces heat, which can burn the DC lines. Similar decreasing trend is also evident in the induced current in presence of the LPS as illustrated in Fig. 7 and Fig. 8. So, our findings demonstrate how a proper LPS would help for the safety protection of a large scale solar power plant.

B. Lightning Effect on PV Frames with and without LPS

The metal frame which holds the PV panels is the main structure of a solar power plant. Due to lightning, a high voltage induces on the frames. This high voltage can damage

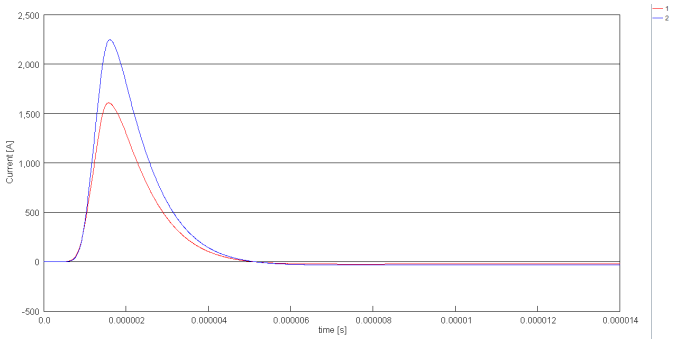

Fig. 7. The induced current in the DC lines without any LPS

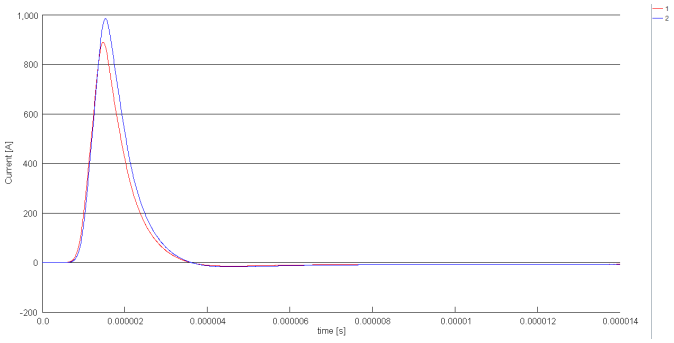

Fig. 8. The induced current in the DC lines with the proposed LPS

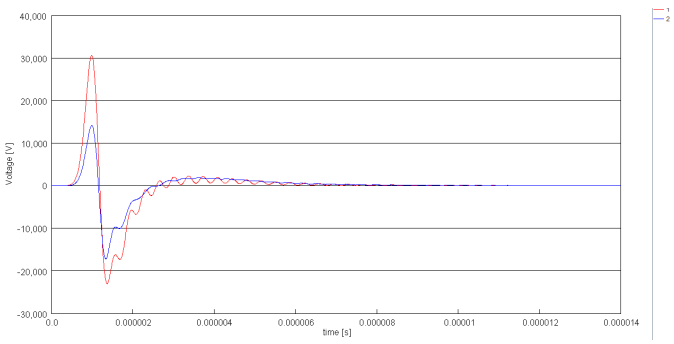

Fig. 10. The induced voltage in the frame with LPS

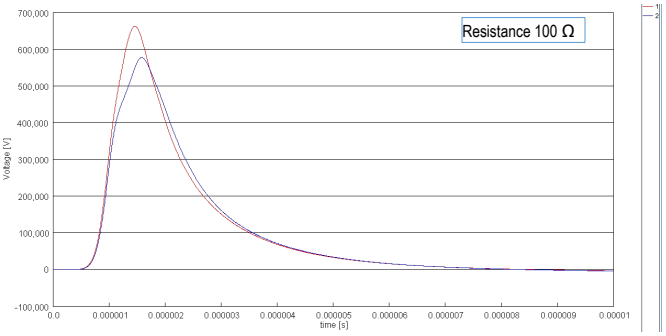

Fig. 11. The induced voltages with the earth-resistance of 100Ω

the PV panels and its wiring. In Fig. 9, it is observed that 74KV and 60Kv voltages induced in two frames. These induced voltages, however, reduced to 30KV and 12KV, when we introduced LPS as illustrated in Fig. 10. The induced voltages in the frames, however, can be further reduced with a more appropriate LPS.

C. Effect of Altering Soil Resistivity

The induced voltage due to the lightning effect also depends on the soil property. Fig. 11 and Fig. 12 show the induced voltage of DC lines leads to the inverter. As illustrated in Fig. 11, we observed that the peak induced voltage is 650KV, when the resistivity of the earth is 100Ω. In contrast, the Fig. 12 illustrates that the result of the induced voltage for the earth-resistance is 5000Ω. The induced voltage is as high as approximately 1000KV, which means that, with the increase of the soil resistivity, the induced voltage due to the lightning also increases. We also note that, at the low soil resistivity, the voltage rises to the peak and then within a few microseconds, it dies down to zero. On the other hand, for a higher soil resistivity, the voltage will not die down; instead, it fluctuates for some times. This dependence on the soil resistivity indicates that the soil resistance is an essential factor for the site selection of a large scale solar power plant. Wetland or swampy land is better than sandy or dry land. So solar power panels can be placed over the swampy land or at the island of a river or sea.

D. Recommendations for Lighting Protection

Considering the massive consequences, lighting has recently been announced as a natural disaster in Bangladesh. The safety protection of the large solar power plants in Bangladesh is therefore a more essential need than the other countries. To

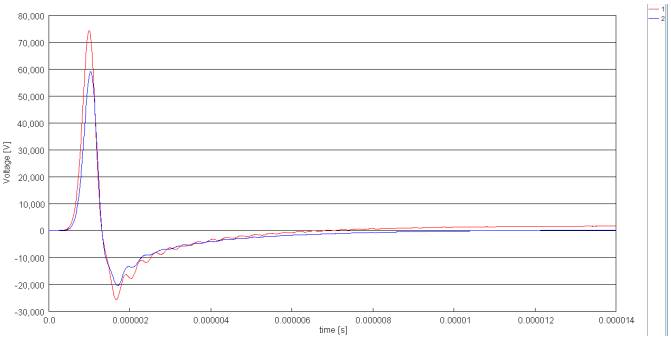

Fig. 9. The induced voltage in the frame without LPS

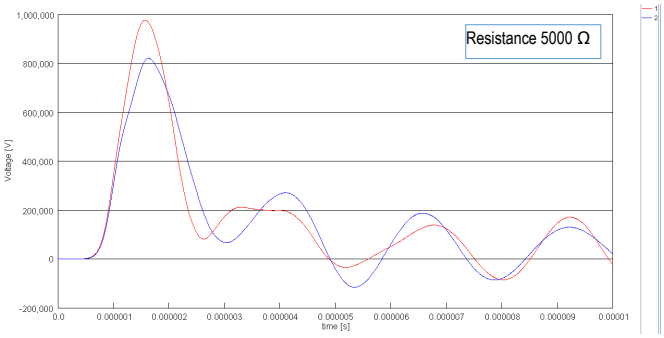

Fig. 12. The induced voltages with the earth-resistance of 5000Ω

design a large scale solar power plant and an appropriate LPS for it, the following recommendations can be made from our above findings and analysis:

1) A dedicated pre-analysis is to be carried out for establishing a large solar power plant to determine the requirements of an appropriate LPS for the plant. A conventional LPS used for the other installations or systems could be inadequate for the required safety protection.
2) An appropriate LPS system should consist of both the set of air-termination and earth-termination systems.
3) Since the low earth-resistance reduces the lightning effect, the solar power plant can be planned in the wet or swampy land.

IV. Conclusions

In this paper, modeling and analysis of a lighting protection system (LPS) is presented for a large scale solar power plant. Characteristics of induced voltage and current due to a lightning strike on the solar power plant has been studied using VSTL simulation software under different conditions, which provides knowledge for designing an appropriate LPS. The protection system for a large scale solar power plant is not yet standardized in many countries like Bangladesh. In this study, we observed that a properly designed LPS can significantly reduce the induced voltage in an acceptable range and thus can protect the PV panels, the frames and DC lines from both the direct and indirect lightning effect. We also found that the induced voltage due to lightning effect increases with the increase of soil resistivity. The location of large scale solar plant should therefore be chosen at the wet or swampy land, which offers low earth-resistance.

The analysis and findings presented in the paper are the outcome of our initial study towards designing an effective LPS system for a large scale solar power plant. Further study may be the choice and use of appropriate metal for air-termination rod and earthing electrodes to reduce the cost of LPS.

***Abstract*— By using ferroelectric material as gate insulator in MOSFET (NCFET), Sub-Threshold Swing can be reduced below the fundamental limit of 60mV per decade. Achieving the negative capacitance depends on the ability to drive ferro-electricity away from its local minimum to non-equilibrium state which is very unstable. It can be stabilized by adding a series capacitance. Hence, a ferroelectric MOS capacitor can be modeled by a series connection of a ferroelectric capacitance and a channel capacitor to get a steeper I_d-V_{gs} curve than a regular MOSFET.**

Keywords—Negative Capacitance MOSFET, Ferroelectric, Hafnium Oxide.

I. INTRODUCTION

The rapid development of technology is commensurate with smaller and more efficient devices. In order to deal with the constant demand for smaller devices, we need smaller transistors. And CMOS being the dominant technology for integrated circuits, has served significantly to this scaling trend. CMOS can be scaled down by reducing its drain to source length (channel length) and the smaller the dimension the higher the performance achieved [1]. Consequently, today's CMOS occupies less than 1% of space compared to the initial transistors while being 20 times faster [2]. Ferro-electricity was first noticed in 1920 but the concept of negative capacitance is not very old. S. Salahuddin et al. first published that negative differential capacitance can be used as gate insulator in MOSFET that can lower the SS value below fundamental limit in 2008 [3]. Later in 2011 A. I. Khan with his fellow researchers demonstrated the effect of negative capacitance in a ferroelectric dielectric hetero-structure using a bilayer of ferroelectric $Pb(Zr_{0.2}Ti_{0.8})O_3$ and dielectric $SrTiO_3$ [4]. C. W. et al. achieved sub-30mV/decade SS in non-hysteretic NCFET using body profile engineering [5]. They also showed that NCFET works best in ultrathin body using TCAD simulation [6]. The first fabrication of NCFET was done in 2014 by C.W. Yeung and his colleagues [7]. Later in 2014 NCTFET was proposed by N. Chowdhury et al. [8] and a direct measurement of negative capacitance in an isolated ferroelectric capacitor was reported by A. I. Khan and his colleagues in 2015 [9]. In the years of 2016-2017 enormous amount of research has been conducted on NCFET. Among them simulation of first NC-FinFET [10], a spice compatible model for NC-FinFET [11],

Table I: Scaling of Parameters

SL.	Constant Field Scaling		
	Description	***Parameter***	***Scaling***
1	Device Dimension	L, W	1/S
2	Oxide thickness	T_{OX}	1/S
3	Channel Doping	N_{SUB}	S
4	Power Supply	V_{DD}	1/S
5	Junction Depth	X_J	1/S

negative capacitance in polycrystalline HfO_2 based thin film [12], a simulation model of NCFET with hysteresis edges less than 10mV/decade up to seven order of magnitude and ultra-low energy delay overhead (below 2.1%) [13], significant improvement in DIBL and NDC (Negative Output Differential Conductance effects) using an ultrathin quantum metallic layer [14], experimental demonstration of ferroelectric HfZrOx (FE-HZO) NCFET with high temperature annealing (hysteresis free) [15], NC MOSFET incorporating with ferroelectric Al doped HfO_2 [16] are some of the significant works.

However, the reduction of channel length generates some undesirable changes in the device characteristics. The most popular constant field scaling scheme (proposed by Robert Dennard and his team) to maintain qualitative performance of MOS requires the oxide thickness and depletion width to be decreased by the same factor as the supply voltage and all the electric field within the device remains constant [Table I]. To keep the power density constant, supply voltage and threshold voltage (V_T) need to be reduced proportionally. On the other hand, to keep the power consumption low, high threshold is required to limit the leakage current. Also the supply voltage must be significantly above the threshold

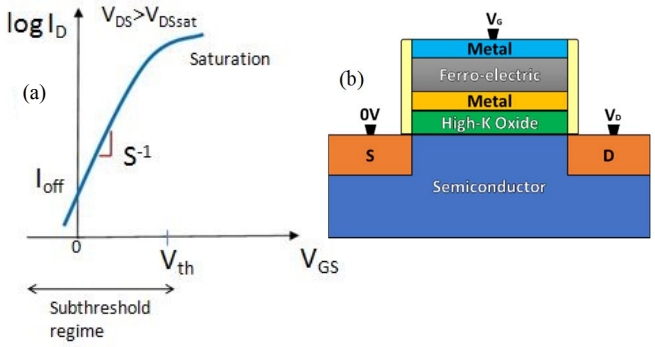

Fig. 1: (a) Here, showing the exponentially decreasing drain current, I_D in the sub-threshold regime known as sub-threshold current. (b) Basic structure of NCFET using ferroelectric material as gate insulator [9].

voltage which eventually limits the power supply to decrease enough to follow the constant field scaling method. Later it was observed that the smaller the device, the more the thermal noise and bit flipping increases in the conventional MOSFET structure. There are also two major types of power dissipation in CMOS - Static (leakage current in the sub-threshold region) and Dynamic (power consumption due to the charging and discharging of the output capacitive load) power dissipation [17].

For simple MOSFET it is assumed that the drain current, I_D is 0 when $V_{GS}<V_T$. However, in reality I_D decreases

exponentially to 0 when $V_{GS}<V_T$ resulting in off state or sub-threshold current. The slope of the sub-threshold current can be shown as $d(V_G)/d(\log I_D)$. This current depends on the depletion capacitance of the channel. Mathematically sub-threshold slope (SS) is defined as,

$$SS=\frac{d(V_G)}{d\log(I_D)}=\left(\frac{kT}{q}\ln 10\right)\left(1+\frac{C_D}{C_{OX}}\right)$$

C_D is the depletion capacitance in the channel. At room temp. (T=300K) substituting $k = 1.3806\times10^{-23} m^2 kg\ s^{-2}\ K^{-1}$, $q = 1.6\times10^{-19}$ C.

$$SS=\left(60\times10^{-3}\right)\left(1+\frac{C_D}{C_{OX}}\right)$$

This means at room temperature with the best case where $C_D \ll C_{OX}$, theoretically the lowest SS can be 60mV/decade. The less the I_{ON} and I_{OFF} ratio, the less the leakage current will be. Therefore, for a high performance this ratio needs to be as low as possible and the SS to be steeper. Since some of the fundamental parameters of MOSFET are reaching its limit, introduction of new structures are necessary. Different transport mechanisms such as impact ionization, tunneling and positive feedback can be applied to improve SS by amplifying the gate voltage [5].

II. Device Structure

With a view to studying the electrical performance of the negative capacitance MOSFET, a metal-FE-metal-insulator-semiconductor (MFMIS) structure is used to approximate the MFIS structure, as shown in Fig. 2. The suspended gate metal is assumed to have the same work-function as the top gate metal, and there are no net charges on the suspended gate. It is obvious that for $V_{ds} = 0$ V or $t_f = 0$ nm, the MFMIS structure is completely reduced to the MFIS device and there are no errors for this approximation. Even though there are some reasonable errors (<10%) depending on specific circumstances for large V_{ds} and t_f values, the errors can be ignored for small V_{ds} or t_f values. And, the latter is the typical case (low power supply and ultra-small dimension) of state of the art nano-scale devices being fabricated. Dynamic nonlocal path band to-band model, standard Shockley-Reed-Hall recombination and drift-diffusion model are used and Fermi-Dirac statistics is assumed in the MOSFET simulation. This hybrid 2D electrostatics for MOSFET and 1-D Landau equations are solved self-consistently.

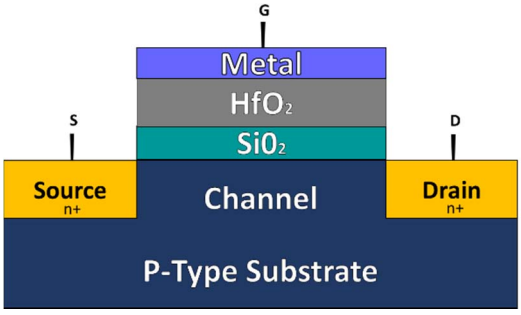

Fig. 2: Device structure of proposed NCFET showing different capacitances.

A. Working Principal

In the ferroelectric MOS capacitor, the ferroelectric polarization charge density and the channel charge density should match. Therefore, a static operation point is determined using the cross point of P-E curve and the channel charge load line. The negative slope of the P-E curve

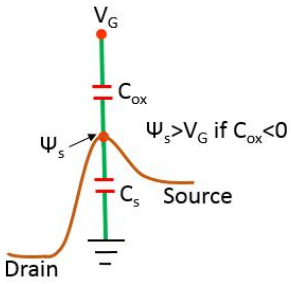

Fig. 3: Schematic diagram of an NCFET.

indicates negative capacitance region. If the two curves have a single cross point in negative capacitance region, the ferroelectric MOS transistor works as NCFET. If the thickness of the FE is too thick, the static operation point cannot be properly set and it shows hysteresis. However, it can be avoided by choosing suitable thickness [18]. For negative capacitance, $\frac{\partial V_g}{\partial \psi_s}=1+\frac{C_S}{C_{OX}}$ can be less than 1 as C_{ox} is negative. Therefore, NCFET seems to have a good potential to work below the SS limit [Fig. 3].

B. Fabrication Process

The fabrication technique of NCFET is a long process that starts with source and drain doping and activation. Then an SOI wafer is thinned down by using dry thermal oxidation and DHF etching. After that active area definition is done followed by the removal process of defects – caused by etching – using thermal oxide. Next steps are wafer patterning, source/drain ion implementation, activation of dopants (using rapid thermal annealing). Then blanket STO buffer is deposited using Molecular Beam Epitaxy (MBE) along with native oxide removal. The wafer is then cut into 10mm by 10mm dies and another blanket layer of ferroelectric is deposited. Finally, the gate metal is deposited by e-beam deposition and using a dry-wet etch process source/drain contact is etched.

C. Si doped HfO_2 as Ferroelectric Material

With enhance research in the nano-field to overthrow the classical limit of 60mV/decade, Salahuddin [19] came with the idea of negative capacitance field effect transistor which has the same structure of a normal MOSFET and the only difference in building criteria is to replace the gate insulator oxide with thin film of ferroelectric material. The nonlinear characteristic of ferroelectric material which is known as negative capacitance plays a vital role to exceed the value of $\partial\psi_s/\partial V_g$ more than 1. While in non-equilibrium, a ferroelectric material can show negative differential capacitance due to its energy barrier that actually forms during the phase transition and separates the two degenerate polarization states. Though the state of negative capacitance is unstable, by using a series die-electric capacitor the negative differential capacitance state can be stabilized.

Here it may be mentioned that negative capacitance has already been experimented on thin ferroelectric film [20]

which surely indicates a new way in the semiconductor industry. It is well known that the mechanism that works behind electron transport system in MOSFET is drift and diffusion and this very same technique also works as the working principle in negative capacitance MOSFET. NCFET can drive higher current than tunnel FET due to its higher charge density on the interface which works as an amplifier in the same off-current. Actually ferroelectric material works as a 'transformer' to boost up the input voltage. As a result, NCFET can successfully exceed the drive current of conventional MOSFET as well as it can surely overcome the limit of 60mV/decade. Moreover it is interesting to note that pass-gate CMOS circuits which actually flow the electricity in both ways between drain and source and standard pull-up and pull-down CMOS logic circuits both can be built by negative capacitance FET. So there is no reason to hugely modify the logic circuit architecture and IP macro design from the conventional MOSFET as it will be simply replaced by the new NCFET which got significant impact on semiconductor industry yet it has got some limitations too. The main barrier comes on the process of integration. In order to balance the large polarization charge density and FET charge density, the thickness of the insulator layer needs to be more than hundreds nanometer in case of traditional ferroelectric material such as Lead Zirconate Titanate and Barium Titanate. And here comes the real challenge as those are not compatible to advanced scale complementary MOS (CMOS) frond-end technologies. In addition to that, heavy metal contamination to the manufacturing line is also a big issue here in this case. Recently it has been found that by controlling crystalline phase of thin films of Hafnium Oxide, ferroelectricity has been observed in HfO_2.

With the 28 nanometer CMOS technology, thin films of Hafnium Oxide have already been implemented in Ferroelectric Random Access Memory (Fe-RAM) successfully [21]. Thereafter if the ferroelectric thin film of Hafnium Oxide is used in NCFET, the fabrication process will fully compatible with CMOS technology. Just by introducing ferroelectric HfO_2 gate insulator NCFET can be fabricated by any CMOS technology from the mature to most advanced technology in a cost efficient way.

III. Numerical Modeling

As discussed earlier, NCFETs are implemented by adding a ferroelectric material layer in the gate stack of MOSFETs. A lower SS is achieved in NCFETs with the help of "negative capacitance" which is contributed by the deposited ferroelectric layer. Ferroelectrics are materials with a high polarizability while ferroelectric capacitors tend to exhibit nonlinear capacitance, where the change in voltage produces a negative change in polarizability. The free energy of ferroelectric is represented by the Landau Theory and the electrostatic dynamics of this negative capacitance can also be well described by LK (Landau-Khalatnikov) equation:

$$\rho\frac{d\vec{P}}{dt}+\nabla_i U=0 \qquad (1)$$

Where, ρ is material dependent parameter that accounts for dissipative process during the ferro-electric switching, P is the polarization charge in per unit area and U is the Gibbs free energy. We can express it in terms of anisotropy energy:

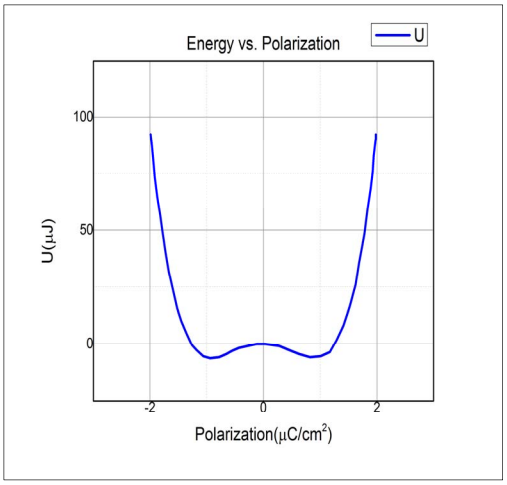

Fig. 4: Energy vs. Polarization.

$$U=\alpha P^2+\beta P^4+\gamma P^6-\vec{E}_{ext}\vec{P} \qquad (2)$$

Here the energy due to the external field is $\vec{E}_{ext}$ and α, β and γ are the material dependent parameters. In general, at zero bias the U vs P graph looks like a W like the one in Fig. 4. which tilts due to increase in V_g. From (1) and (2) we can write that:

$$E_{ext}=2\alpha P+4\beta P^3+6\gamma P^5+\rho\frac{dP}{dt} \qquad (3)$$

here the vector signs have been dropped assuming the spatial variations to be one-dimensional. It is easy to see that if we set, at steady state operation $dP/dt \approx 0$ and for FE material $P \approx Q$ while the external electric field is $E_{ext} = V/t_{ins}$ them taking all these into consideration and mingling (2) and (3) we get,

$$V=2\alpha t_{ins}Q+4\beta t_{ins}Q^3+6\gamma t_{ins}Q^5 \qquad (4)$$

where, t_{ins} is the ferroelectric insulator thickness and α, β and γ are the material dependent parameters. For, HfO_2 the values of these parameters are -1.5877 x 10^{11} m/F, 9.8007 x 10^{20} $m^5/F/Coul^2$ and 0 $m^9/F/Coul^4$ respectively. The plot of the steady-state polarization P versus E_{ext} and V vs P are shown in Fig. 5 and Fig. 6, were obtained from (3) and (4).

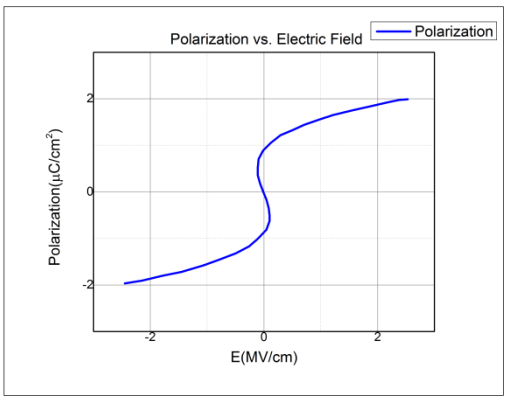

Fig. 5: Polarization vs. Electric Field.

We will consider that the FET has a ferroelectric insulator rather than an ordinary insulator at the gate. So, the gate circuit can be assumed to be a series combination of the ferroelectric capacitor and another capacitor that we will call C_s, representing semiconductor, channel-to-source and channel-to-drain capacitances. For this series combination, a voltage ψ_s appears across C_s, while the rest V_g-ψ_s appears across the ferroelectric such that both have the same charge Q and we can write:

$$\psi_s = Q/C_S \tag{5}$$

$$V_g - \psi_s \approx \alpha_0 Q + \beta_0 Q^3 + \gamma_0 Q^5 + \rho_0 \frac{dQ}{dt} \tag{6}$$

Considering $\alpha_0 = 2\alpha t_{ins}$, $\beta_0 = 4\beta t_{ins}$, $\gamma_0 = 6\gamma t_{ins}$

Reconsidering (3) and by combining these expressions, we can relate the applied voltage V_g to the potential ψ_s that appears inside the channel:

$$\tau \frac{d\psi_s}{dt} + (1+a_1)\psi_s + a_2\psi_s^3 + a_3\psi_s^5 = V_g \tag{7}$$

Where $\tau = \rho C_S t_{ins}$. By setting $d\psi_s/dt = 0$, the steady-state ψ_s versus V_g is obtained from (7) which is

$$(1+a_1)\psi_s + a_2\psi_s^3 + a_3\psi_s^5 = V_g \tag{8}$$

There is no doubt that the nature of the ψ_s vs V_g characteristics will very much depend on the three co-efficient a_1 and a_2 and a_3 which are scaled versions of the material parameters α, β and γ. If the parameter values are such that the nonlinear terms a_2 and a_3 are very small

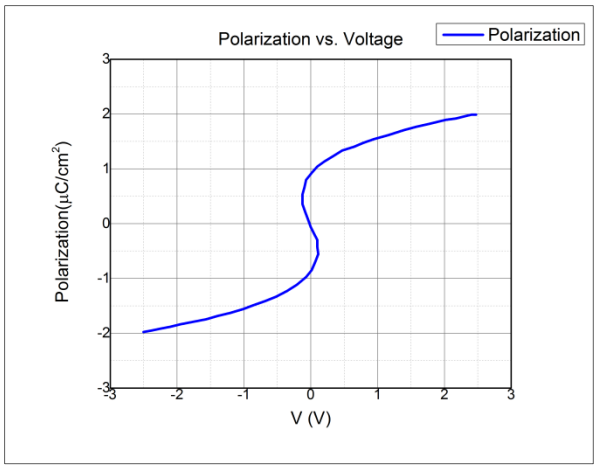

Fig. 6: Polarization vs. Oxide Voltage.

compared to a_1, which only ensures the relation between ψ_s and V_g is linear then

$$\partial V_g/(\partial \psi_s) \approx 1 + a_1 \tag{9}$$

This is same as $\frac{\partial V_g}{\partial \psi_s} = 1 - \frac{C_s}{C_o}$ $(\alpha_f C_o - 1)$ which represents the negative capacitance while it seems that we are neglecting the nonlinear terms. But the point to be noted that even though a_2 and a_3 are non-negligible, $(1+a_1)$ represents the slope close to the origin $\psi_s = 0$ & $V_g = 0$ and should be positive if we wish the origin to represent a stable operating point. With the help of a_1, it is easy to find that the condition $(1+a_1) > 0$ requires the thickness of the ferroelectric insulator to be less than a critical thickness defined as:

$$t_{ins} \leq \frac{1}{2|\alpha| C_s} \equiv t_c \tag{10}$$

The above condition confirms that the ferroelectric capacitor is large enough or the series capacitor C_s is small enough that the combination forms a stable positive capacitor, and there is no hysteresis at the origin unlike Fig. 7, which corresponds to a very thin ferroelectric. All results we present below assume $t_{ins} < t_c$, because a hysteresis at the origin seems undesirable for our device applications.

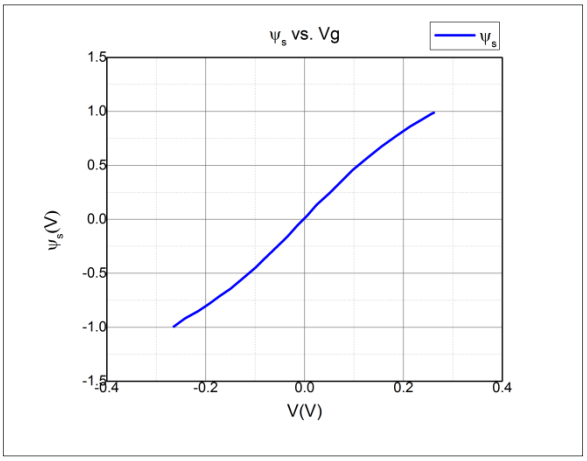

Fig. 7: ψ_s vs V_g

Fig. 7 shows ψ_s vs V_g for different values of t_{ins}, directly obtained from (8) using appropriate values of α, β and γ for HfO_2, in series with a linear capacitance $C_s = 25 \times 10^{-7}$ F/cm^2. The plots are obtained starting from an initial state with the ferroelectric capacitor fully negatively polarized, sweeping the voltage toward the positive maxi-mum, and then sweeping it back again to the negative maximum. Each point is obtained by solving the full-time dependent (1) and then finding ψ_s as the system reaches a steady state. Here also one thing may be noted that the insulator thicknesses we use are less than the critical thickness.

As the insulator thickness is increased, the ψ_s vs V_g plots become progressively steeper but at the same time, they start to show more and more hysteresis away from the origin but not at the origin due to the nonlinear terms a_2 and a_3. With more insulator thickness there is a hysteresis in ψ_s vs V_g away from the origin, but it is small. In general, a trade off will take place between steepness and hysteresis, unless materials can be engineered to minimize the nonlinear term β relative to the linear term α so as to avoid hysteresis even at large steepness.

It will be noted from a_1 and a_2 and a_3 that if C_s were smaller, the nonlinear terms a_2 and a_3 would become smaller in comparison to the linear term a_1 making the hysteresis negligible in our voltage range of interest. The value for C_s that we have used in this paper is more appropriate for ultra-small FETs [22] where the short

channel effects are significant. For present day commercial device, the value of C_s should be roughly a factor of 10 lower than that used in this paper and as such should show steep ψ_s vs V_g with negligible hysteresis. However, because the critical thickness is inversely proportional to C_s, the thickness of the ferroelectric insulator will have to be roughly a factor of 10 larger.

In terms of a free energy functional, the voltage amplification arises from an internal interaction commonly described by the Landau theory. Such interactions are quite general in metal oxides and commonly lead to the development of a spontaneous order parameter below a transition temperature. For example, the giant enhancement of longitudinal piezoelectric response recently modeled using the Landau-Ginzburg-Devonshire theory can be attributed to similar mechanisms, the precise correspondence between the effective field in the Landau approach in (3) and the effective voltage in a capacitor with positive feedback suggests that any microscopic mechanism that can provide the necessary positive feedback can be used to implement a step-up voltage transformer that would allow low-voltage/low-power operation of conventional FETs. For a ferroelectric capacitor, it is the dipole interaction that provides the positive feedback while avalanche breakdown, polaronic effect, etc. within the oxide can possibly provide the positive feedback needed for negative capacitance as well. The parameters α_o, β_o , γ_o and ρ_o will be determined by the specific mechanism involved.

A. Negative Capacitance Region

Capacitance C at a given charge Q_F is related to the potential energy U by the relation $C=[\frac{d^2U}{dQ_F^2}]^{-1}$. The parabolic graph is in Fig. 8. So, we can call the negative capacitance as negative differential capacitance. For a ferroelectric material, as shown in Fig. 8, the capacitance is negative only in the barrier region around P=0 [Considering $Q_F \propto P$]. Starting from an initial state,

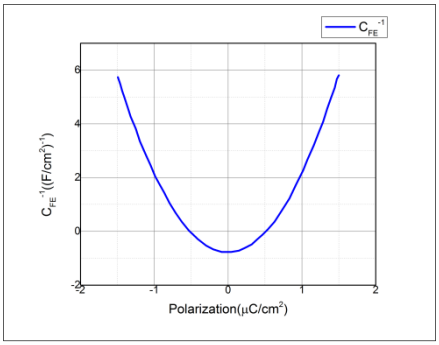

Fig. 8: Capaitance^{-1} vs Polarization

as voltage is applied across the ferroelectric capacitor, the energy landscape is tilted and the polarization will move to the nearest local minimum. Fig. 9 (a), Fig. 9 (b) are the graph for less than the coercive voltage whereas Fig. 9 (c), Fig. 9 (d) show this transition for a voltage that is greater than the coercive voltage V_c. If the voltage is larger than coercive voltage, one of the minima disappears and P moves to the remaining minimum of the energy landscape showed in the figure. Here may be noted that, as the polarization state descends, it passes through the region where $C=[\frac{d^2U}{dQ_F^2}]^{-1}<0$. Therefore, while switching from one stable polarization to the other, a ferroelectric material passes through a region where the differential capacitance is negative. And this is the region where the device we are working on should work.

In case of P-E curve where the slope is negative, we find the negative capacitance but it is unstable and not directly observed in experiments when it exhibits hysteric jumps in the polarization. Here is a solution for the unstable condition, if we place a ferroelectric capacitor series with a normal capacitor then the negative capacitance segment can be effectively stabilized. It is possible by making ψ_s on an internal node to change more than the voltage applied V_g externally working as a voltage amplifier also known as step-up voltage transformer.

The structure of the device may be a bulk Si MOSFET with high K gate oxide is referred to as the intrinsic MOSFET. FE oxide is assumed to be deposited on a commensurate metallic template grown on the oxide. The intermediate metallic layer between the FE and the high-K gate oxide is chosen following the experimental device. This layer averages out the non-uniform potential profile along the source-drain direction as well as any charge non-uniformity coming from domain formation in the ferroelectric. This experimental structure therefore justifies using a 1-D Landau model for the ferroelectric.

IV. Result

The intrinsic MOSFET is simulated using TCAD Sentaurus software taking into account the 2-D electrostatics. NCFET with an MFIS structure cannot be simulated directly even with state-of-the-art device simulators such as Sentaurus and Silvaco TCADs, because of the lack of a corresponding accurate FE polarization model. In order to study the electrical performance of the NCFET, a metal-FE-metal-insulator-semiconductor (MFMIS) structure is used to approximate the MFIS structure. The suspended gate metal is assumed to have the same work-function as the top gate metal, and there are no net charges on the suspended gate. It is obvious that for V_{ds} = 0 V or t_f = 0 nm, the MFMIS structure is completely reduced to the MFIS device and there are no errors for this approximation. Even though there are some reasonable errors (<10%) depending on specific circumstances for large V_{ds} and t_f values, the errors can be ignored for small V_{ds} or t_f values. And, the latter is the typical case (low power supply and ultra-small dimension) of state-of the-art nano-scale devices being fabricated. Dynamic nonlocal path band to band model, standard Shockley-Reed-Hall recombination and drift-diffusion model are used and Fermi-Dirac statistics is assumed in the MOSFET simulation. This hybrid 2D electrostatics for MOSFET and 1-D Landau equations are solved self-consistently. One significant point is that, negative capacitance regions are ordinarily unstable and not observed in experiments. But placing such a capacitor in

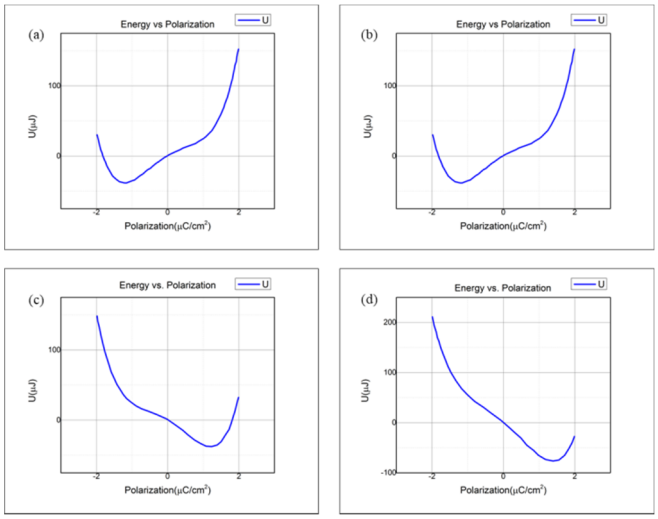

Fig. 9: Energy vs Polarization curve at (a) V_g= -6 V, (b) V_g = -3 V (c) V_g = 3 V & (d) V_g = 6 V.

series with a positive capacitor stabilizes it by making the effective α of the composite capacitor positive, provided its thickness is less than the critical thickness defined in (10). As R is proportional to (T-T_c) with T_c being the Curie Temperature, the series combination acts like a ferroelectric at a temperature above its T_c. After simulation, we get the I_D-V_{gs} curve in liner and in logarithmic scale as below which clearly shows that using Si doped HfO_2 as ferroelectric material in NCFET device provides much steeper curve of 30mV per decade than other regular MOSFET devices.

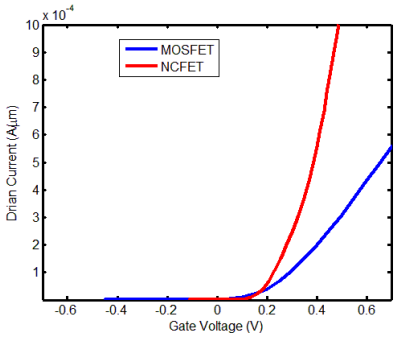

Fig. 10: Drain current in linear axis for MOSFET & NCFET. [V_{ds} = 0.5V]

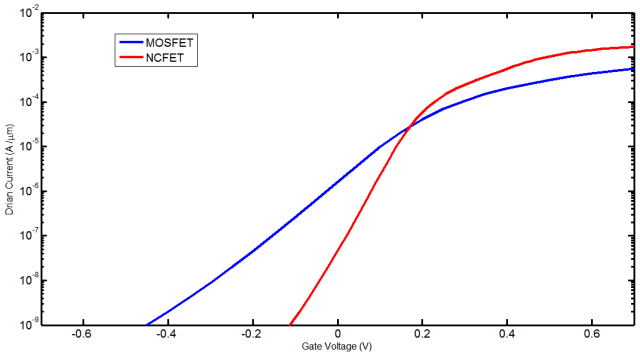

Fig. 11: Drain current in log. axis for MOSFET & NCFET. [V_{ds} = 0.5V]

V. CONCLUSION

HfO_2 as ferroelectric material has showed comparatively better performance than other materials in voltage amplification and low power dissipation. Besides, overall NCFET overcomes the limitations and boundaries faced by other FET devices. It may be said that HfO_2 based NCFET can lead to a better performance FET device in real in near future.

***Abstract*—Almost all the conventional linear generators uses neodymium iron boron (NdFeB) permanent magnets (PMs) to generate magnetic field where neodymium is one of the rare earth elements (REEs). In this paper, a new alternative rare earth free (REF) PM is proposed to be used in the construction of a linear generator for wave energy extraction. The REF PM is a compound of iron nitride which is symbolized as $Fe_{16}N_2$. It is capable to produce strong magnetic field and has large magnetic remanence property. A linear generator is designed and simulated to compare the results for using both $Fe_{16}N_2$ compound and the conventional PM. The construction of the proposed linear generator, generated voltage, power output, armature current, and magnetic properties are shown in detail. Simulation results of the proposed linear generator are obtained by finite element analysis. ANSYS/Maxwell software is used to find excellent performances of the proposed linear generator.**

Keywords—cooling, energy conversion, generators, HVAC, permanent magnet machines, renewable energy sources, wave power.

NOMENCLATURE

i_a	Current of phase-A
i_b	Current of phase-B
i_c	Current of phase-C
i_d	Direct axis current
i_q	Quadrature axis current
I_m	Maximum value of armature current
ϖ	Angular frequency
α	Phase angle of i_a with respect to time origin
θ	Power factor angle

I. INTRODUCTION

Most of the electricity generation systems in the world are using fossil fuels which are well-known for carbon di oxide emissions [1]. This fact increases the atmospheric temperature for which the ice in the polar area is melting. On the other hand, the population is growing fast day by day. To overcome the challenges of meeting the electrical power demand, ensuring sustainable and green energy is very significant.

At present, many types of renewable energy are harnessed for the generation of electrical power for their environment friendly feature [2]. The renewable energies are wind, thermal, solar, and oceanic wave energy (OWE) [1]. Among these, the OWE has some advantages such as much availability, high power density, and long life span [3].

In order to achieve electric energy security, some countries have taken steps already for developing oceanic wave energy converter. China has established some projects to get 15% of energy from renewable sources [4] from which 21.79 GW electricity is expected to be generated from oceanic tidal and wave energy. US government looks into the affect of incentive and economic factors for the conversion of electrical energy from oceanic wave [5]. The European Union has targeted for the production of 100 GW electricity from sea wave and tidal energy within 2050 [6].

Recently, researcher's have presented extensive works in order to develop the oceanic wave energy converter (OWEC). A prototype of an overtopping type offshore OWEC is constructed in [7] which is consisted of automatic control panel and hydro turbine mechanism. A hydraulic system based OWEC is discussed in [8]. A direct drive linear generator (DDLG) is designed in [9] in which the electrical power output is enhanced using a high flux density magnetic core named Supermendur. Another DDLG is presented in [10] where N28H permanent magnet is used for withstanding in high temperature. A superconducting armature coil based linear generator is proposed in [11] which supplies more output power than that of using copper conductor. Another DDLG is presented in [12] where detent force is reduced by skewing the permanent magnets. A DDLG is proposed in [13] where its permanent magnets contain a rare earth element. Temperature effects of a DDLG during its operation are analysed in [14].

The rotational OWECs are presented in [7], [8] and DDLGs are presented in [9]–[14]. In general, DDLG is more popular topology than rotational OWEC owing to remove the complex mechanical structure [15]. Some drawbacks such as large weight and low power density due to low speed of sea wave are found from the conventional DDLG. The probable disadvantages of conventional DDLGs are solved in [16] by increasing the speed of movable magnetic field. Most of the conventional DDLG is consisted of neodymium iron boron (NdFeB) magnet [12]–[14] which is composed of a rare earth element and has limited stock. For this reason, it is necessary to search another type of magnet for the design and construction of linear generators. The compound $Fe_{16}N_2$ PM is found in [17] which has high magnetic energy product and can solve the drawbacks of NdFeB.

In this paper, $Fe_{16}N_2$ compound is proposed to construct a linear generator to avoid the use of rare earth elements (REEs) such as in NdFeB. $Fe_{16}N_2$ has the property of large magnetic remanence and energy product. The mathematical model, characteristics of the generator and performance are presented in detail. Simulation results show that, the proposed linear generator can generate adequate output power which is supplied to different loads to test its effectiveness.

II. Wave Energy Conversion System

The electricity generation system from sea wave is described in Fig. 1. It has some vital components such as linear generator, rectifier, inverter, transformer, and a floating buoy.

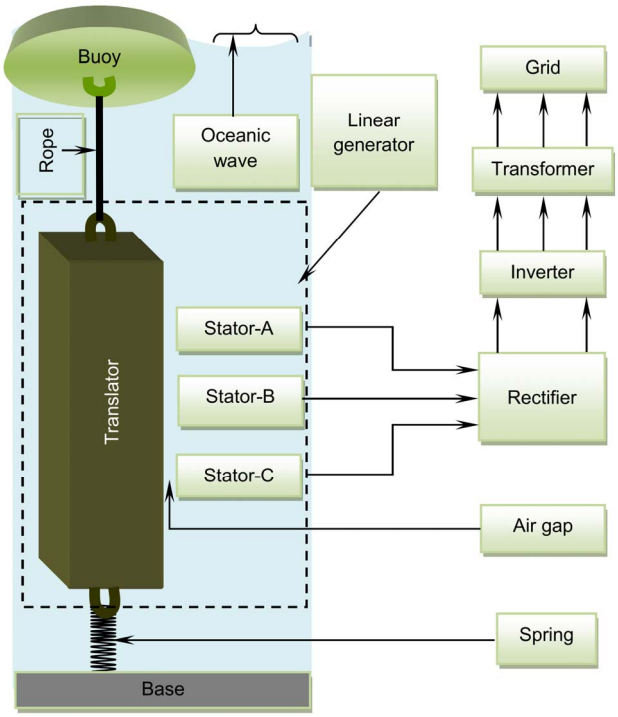

Fig. 1. Oceanic wave energy conversion system.

The effective elements of a linear generator are translator and stator. The translator moves with floating buoy as it is connected to a high strength rope. The translator speed is almost identical to the buoy speed whereas the stators are stationary. When the translator moves with respect to stators, emfs are induced in the stator windings. The frequency of generated voltage varies with the speed of translator/wave since most of the generators are synchronous. Therefore, the frequency of generated voltages are required to match the frequency of grid.

The generated voltages are supplied to the input of a rectifier so that, it can be converted into dc voltage. Further, the dc voltages are fed to the input of an inverter. The inverter is a power electronics device that converts dc voltage to ac voltage and capable to control both the voltage and frequency. A step up transformer is connected between the grid and inverter. The power electronic device such as phase locked loop takes signals from the grid and supplies required voltages with proper phase angle through the transformer by synchronizing it.

III. Comparisons of the Magnetic Characteristics

NdFeB permanent magnet consists neodymium which is a REE and it has much coercivity and remanence magnetism. Figs. 2 and 3 show the temperature dependencies of these two conventional NdFeB PMs, one is N28EH and the other is N35M. It is found that, both the PMs have high energy product at low temperature. With the increase in temperature, the coercivity becomes lower for both the PMs. Alnico PMs can withstand at higher temperature because it has high curie temperature. On the other hand, $Fe_{16}N_2$ compound has large remanence magnetism. Fig. 4 shows the hysteresis loop of $Fe_{16}N_2$ for different conditions and also its magnetic energy product.

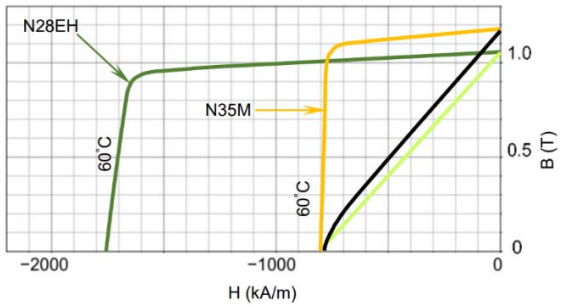

Fig. 2. Comparsons of two NdFeB magnets considering 60□ temperature.

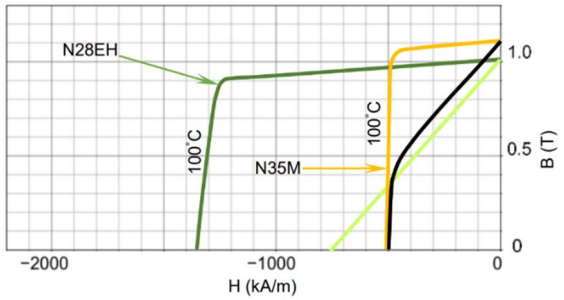

Fig. 3. Comparsons of two NdFeB magnets considering 100□ temperature.

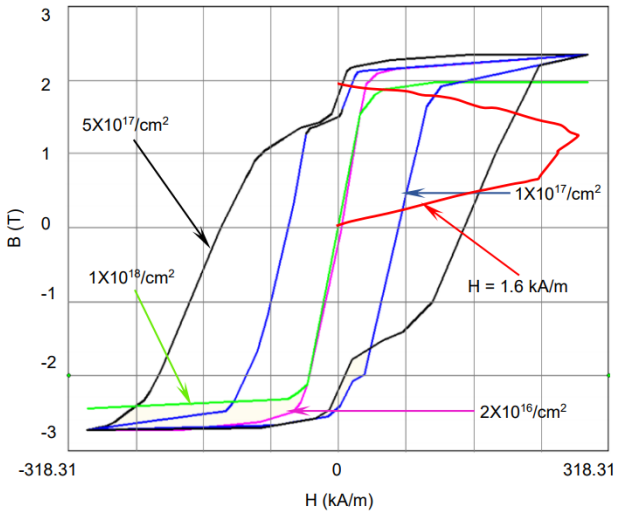

Fig. 4. Characteristics curves of proposed $Fe_{16}N_2$ PM.

The comparisons among different types of PMs are presented in Fig. 5 which includes Ferrite, ordinary and high grade Alnico, NdFeB with the proposed one. It is observed that, magnetic remanence of $Fe_{16}N_2$ is larger than any other existing PMs.

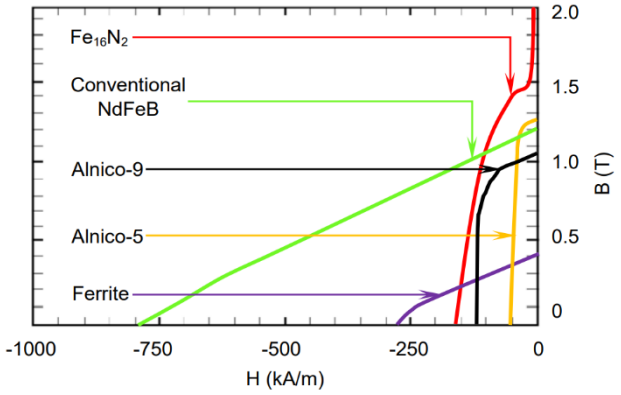

Fig. 5. Comparisons among different types of permanent magnets.

IV. Construction and Model of the Proposed Linear Generator

Fig. 6 illustrates the construction of the proposed linear generator where the translator is consisted of ferromagnetic core and PMs. The cutaway view of two major components namely translator and stator are shown. Windings are placed inside the stator cores.

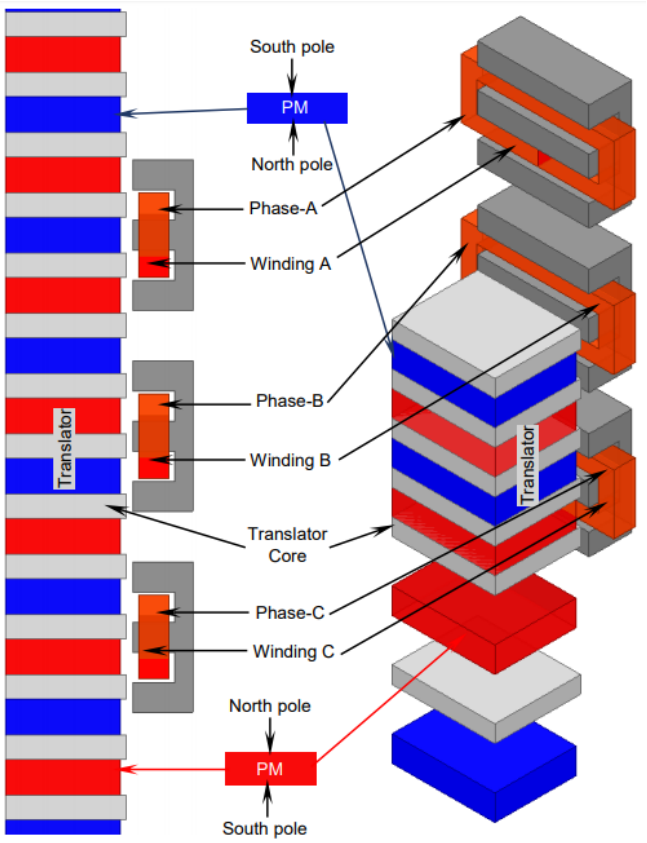

Fig. 6. Structure of proposed linear generator.

The width of proposed linear generator is 0.18m. The length of translator is designed 1.02m. The height of winding and magnetic core are 0.025m and 0.125m, respectively. On the other hand, the width of stator's core and winding are 0.05m and 0.07m, respectively.

The basic two pole machine of the proposed linear generator is presented in Fig. 7. The field winding is shown in direct axis (*d*-axis) and the armature winding A, B, and C are placed by 120°.

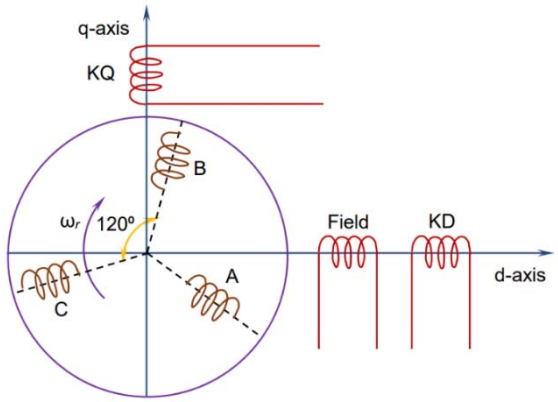

Fig. 7. Basic two pole representation of proposed linear generator.

Here, KD and KQ represent the *d*- and *q*-axis components of amortisseur winding, respectively. The proposed linear generator avoids the amortisseur. Three phase currents denoted as i_a, i_b, and i_c can be expressed in the following.

$$i_a = I_m \cos(\omega t + \alpha) \tag{1}$$

$$i_b = I_m \cos(\omega t + \alpha - \frac{2\pi}{3}) \tag{2}$$

$$i_c = I_m \cos(\omega t + \alpha - \frac{4\pi}{3}) \tag{3}$$

Hence, the d-axis current becomes,

$$i_d = \sqrt{\frac{2}{3}}\left[i_a \cos\theta + i_b \cos\left(\theta - \frac{2\pi}{3}\right) + i_c \cos\left(\theta - \frac{4\pi}{3}\right)\right] \tag{4}$$

where, θ is the equal to ωt and putting the value of i_a, i_b, and i_c in [4],

$$i_d = \sqrt{\frac{2}{3}} I_m \frac{1}{2}(3\cos\alpha)$$

$$= \sqrt{\frac{3}{2}} I_m \cos\alpha \tag{5}$$

Similarly,

$$i_q = \sqrt{\frac{3}{2}} I_m \cos\alpha \tag{6}$$

V. Simulation Results

In the simulation setup, the translator of the proposed linear generator is moved vertically with respect to stationary stator at 1 m/s speed. The air gap length between the stator and translator is selected 1 mm. In the parameter setup, 58 MS conductivity for copper and 7.9 g/m^3 steel core's specific gravity are considered. The generated voltage and armature currents are plotted in Fig. 8.

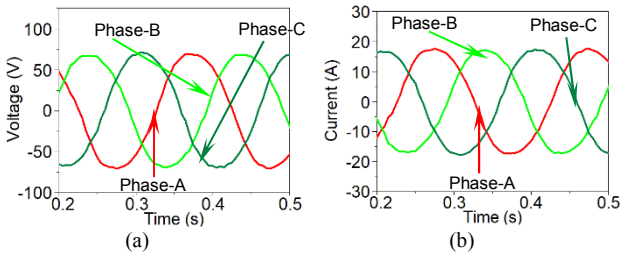

Fig. 8. Simulation results of proposed linear generator: (a) induced voltages and (b) load currents.

Here, the proposed linear generator produces 70V (phase voltage) approximately. The load current is found approximately 17A as shown in Fig. 8(b). The output power is plotted in Fig. 9(a) where approximately 660 W rms power is delivered from each phase. In Fig. 9(b) the flux linkages are shown where the peak value is around 2.5 Wb.

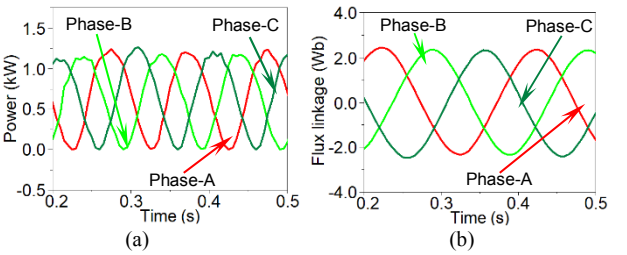

Fig. 9. (a) Output power and (b) magnetic flux linkage of the proposed linear generator.

The comparison of rms power output for using Alnico-9 and $Fe_{16}N_2$ in the linear generator is presented in Fig. 10(a). The generator made of proposed $Fe_{16}N_2$ produces more rms output power compared to that of using the others. Fig. 10(b) depicts the core loss profile of the linear generator using the proposed iron nitride component.

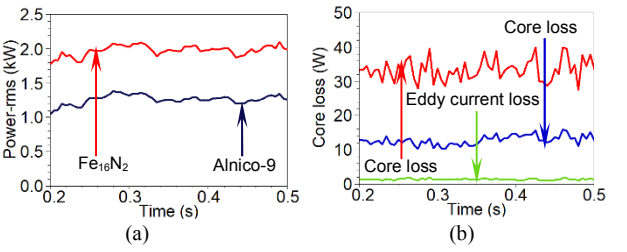

Fig. 10. (a) Output rms power for using the conventional and the proposed material and (b) core loss components of the linear generator using $Fe_{16}N_2$.

The magnetic field intensity and flux density of the proposed linear generator are shown in Figs. 11 and 12, respectively. Table I shows distinguished comparisons of the parameters using Alnico-9 and $Fe_{16}N_2$ in the linear generator. The output parameters of the proposed PM based generator are better than that of using Alnico-9 PM.

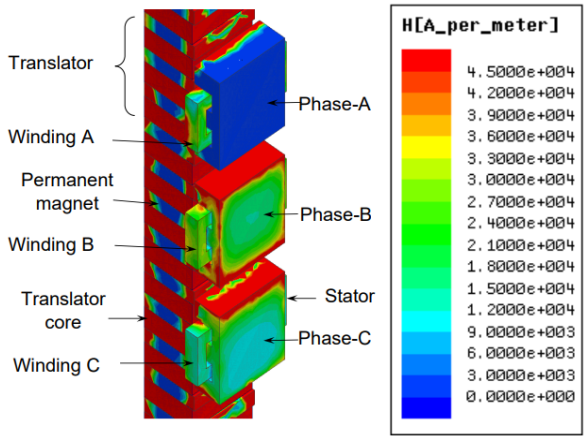

Fig. 11. Field intensity of proposed linear generator.

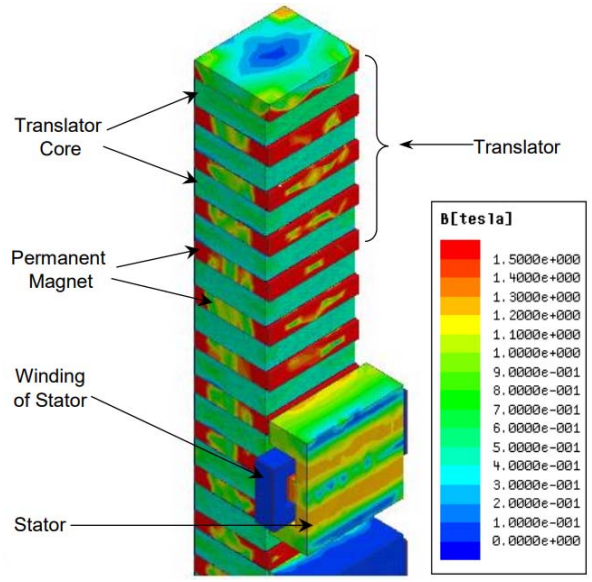

Fig. 12. Flux density of proposed linear generator.

TABLE I. Comparisons of the Parameters using Alnico and the Proposed Iron Nitride Compound

Name of the parameters	Using AlNiCo	Using $Fe_{16}N_2$
Peak generated voltage (V)	57.48	71.06
Peak load current (A)	−14.37	−17.76
Peak magnetic flux linkage (Wb)	1.51	1.78
Peak instantaneous power (W)	826.2	1262.64
Average output rms power (W)	1273.43	1974.83

VI. Conclusions

This paper proposes a linear generator in which nitrogen ion implanted $Fe_{16}N_2$ compound is used as permanent magnet to produce magnetic flux. The remanence and saturation magnetic flux density of the proposed $Fe_{16}N_2$ PMs are quite high. The characteristics curves of the existing PMs and the proposed $Fe_{16}N_2$ are presented and compared. The exciting feature of $Fe_{16}N_2$ compound is that, both Fe and N are REF materials and abundant in nature. Bulk production of PMs is

highly prospective for this compound. To produce the highest output power, proper selection of operating point from the characteristics curve is obvious which is shown in Fig. 4. From the analysis of magnetic properties it is found that there is a good flux linkage in the proposed linear generator.

***Abstract*— FinFET has become extremely popular in recent times by virtue of its ability to suppress short channel effects (SCEs) in nanometer regime. In this work, we study and compare the electrical characteristics of multigate FinFETs (triple gate, Pi gate, Omega gate and Gate-All-Around (GAA)) and the effect of high-k dielectric oxide stack on the performance of multigate FinFETs. It is found that employing high-k dielectric gate stack reduces short channel effects (SCEs), subthreshold slope, leakage current and alleviates switching characteristics. Also, the superior ability of GAA FinFET to overcome SCEs is also noticed.**

Keywords*— *FinFET, multigate FET, Short channel effects, high-k dielectric, oxide stack

I. INTRODUCTION

In the past few decades, semiconductor industry has undergone a revolutionary change. This revolution is made possible by continuous scaling of transistors. With the reduction in transistor size, the number of transistor in a single chip has been increasing exponentially as predicted by Moore's law [1]. Downscaling of transistors improves device speed, functionality lowers power dissipation and reduces the overall cost of an IC[2][3]. However, in recent years MOSFET scaling has reached a limit owing to the Short Channel Effects (SCEs). In short channel MOSFETs, control of gate over the channel region is weakened, causing an increase in leakage current and SCEs. To continue the scaling, while keeping the SCEs at a optimum value multigate FETs are introduced. In multigate FETs the effective number of gates is increased, thus, improving the electrostatic control of the channel by the gate and suppressing SCEs [4].

FinFET is a variation of multigate FET where a rectangular Fin shaped channel is wrapped around by gate and the Fin is accommodated in a silicon-on-insulator (SOI) interface. FinFETs can have a tri gate structure or a slight modification of the tri gate structure (Pi gate and Omega gate)[5]. When the gate surrounds from all four sides, it is called Gate-All-Around (GAA) structure.

Scaling below 2nm of the gate oxide thickness is not a viable option, because it poses to tunneling current[5]. As the device is scaled down to nanometer regime, the gate oxide thickness (t_{ox}) reduces to a great extent such that SiO_2 can no longer be used as gate dielectric because of electron tunneling through the gate oxide [6]. As a consequence, gate leakage current increases exponentially [7]. To overcome this situation, high-k dielectric with higher relative permittivity (k) than SiO_2 is used instead of SiO_2. But the use of high-k dielectric is limited as a result of high fringing field. The fringing fields originating from the drain reduces the potential barrier and increases leakage current [6][8]. An alternate solution to this problem is using gate stack oxide where high-k dielectric is deposited on top of a thin silicon oxide layer instead of direct deposition.

In this paper, the impact of stack oxide on major electrical parameters of 8nm SOI multigate FinFETs is investigated and compared. The different FinFET structures discussed in this work are triple gate, Pi gate, Omega gate and GAA. The comparison is achieved by altering the high-k dielectrics in the oxide stack between the gate and the Silicon Fin. The dielectrics explored in this research are Silicon Oxide (SiO_2), Silicon Nitride (Si_3N_4), Hafnium Oxide (HfO_2) and Hafnium Silicate ($HfSiO_4$). The parameters considered in this work are Subthreshold Slope (SS), Drain Induced Barrier Lowering (DIBL), on current (I_{on}), off current (I_{off}) and I_{on}/I_{off} ratio. Silvaco Atlas 3D simulator is used for performing the simulation [9]. The simulation takes into account Shockley-Read-Hall model (SRH) and Lombardi mobility model (CVT) for physical modeling of the devices.

The paper is organized into four sections. Section I introduces the work and section II demonstrates the simulated device structure and the simulation methodology. Section III provides the obtained result and the analyses. The paper is concluded in section IV.

II. DEVICE STRUCTURE AND SIMULATION SETUP

In this work, we have studied the effect of stack oxide on four different FinFET structures. Fig. 1 illustrates the cross-sectional view of the FinFET structures. The first structure is a triple gate FinFET and the second structure is Pi gate FinFET. The two structures on the bottom are Omega and GAA FinFET. All the structures are SOI structures having the silicon fin on top a SiO_2 layer. The simulation has been done with 8nm gate length. The Silicon Fin has a height (H_{fin}) of 8nm and a width (W_{fin}) of 4nm. The oxide layer between gate metal and silicon fin has a thickness (t_{ox}) of 1nm. The work function (ϕ) of gate metal is 4.7 eV. In the source and the drain region, the doping concentration (N_d) is $9x10^{19}$ cm^{-3}, whereas the doping concentration (N_a) on the channel region is $9x10^{15}cm^{-3}$.

The simulation is performed using Silvaco TCAD software. At first, the structures are designed using DevEdit tool and then the electrical characteristics are analysed using Atlas device simulator. The models used in this simulation are Shockley-read-hall model (SRH)[10] and Lombardi mobility model (CVT). SRH model is used for considering the interface trap effect and the presence of high impurity atom in the channel region. The mobility model (CVT) takes into account both concentration and parallel field dependence.

The metal gate technology is efficacious when the device is scaled to smaller and smaller dimensions with high-k dielectrics [11]. The oxide layer is varied for single oxide and also for dual-k stack oxide.

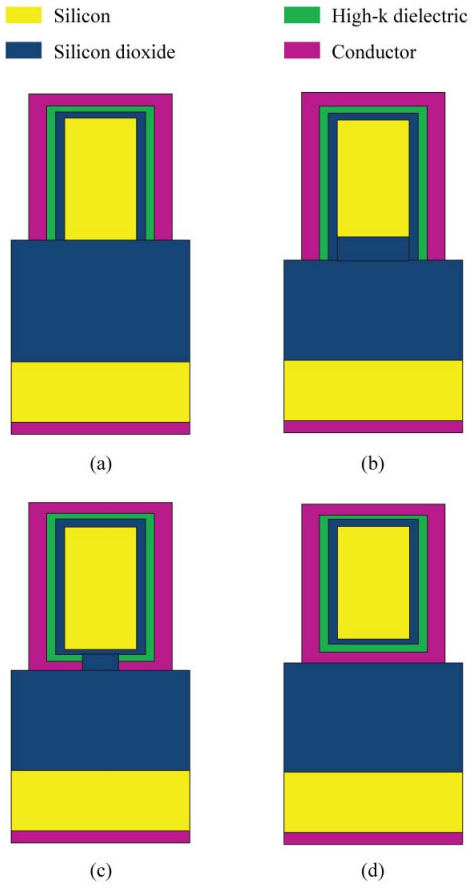

Fig. 1. Cross sectional view of (a) Tri gate, (b) Pi gate, (c) Omega gate, and (d) GAA FinFET structure

TABLE I. DIELECTRIC MATERIALS AND THEIR DIELECTRIC CONSTANTS

Dielectric Material	Dielectric Constant (k)
Silicon Oxide (SiO_2)	3.9
Silicon Nitride (Si_3N_4)	7.5
Hafnium Silicate ($HfSiO_4$)	12.0
Hafnium Oxide (HfO_2)	22.0

The dielectric materials employed are Silicon Oxide, Silicon Nitride, Hafnium Oxide, and Hafnium Silicate. The dielectric constant of these materials is listed on table I.

III. RESULTS AND DISCUSSION

The key electrical parameters Subthreshold Slope (SS), Drain Induced Barrier Lowering (DIBL), On current (I_{on}), Off current (I_{off}) and I_{on}/I_{off} ratio are evaluated using Silvaco Atlas. The high-k dielectrics can be deposited in two methods-first one is direct deposition which can deteriorate the electrical characteristics of device and second one is known as gate-stack (GS) which contains a very thin layer of SiO_2 grown on Si substrate, over which a thick layer of high-k dielectric deposited [15].In this section, the parameters and their interrelation with multigate FinFET devices having varying stack oxide will be discussed.

A. Impact on Subthresold Slope (SS) and DIBL

Subthreshold slope (SS) is a key electrical parameter for evaluating the current below the threshold voltage. SS is defined by the relationship [12]:

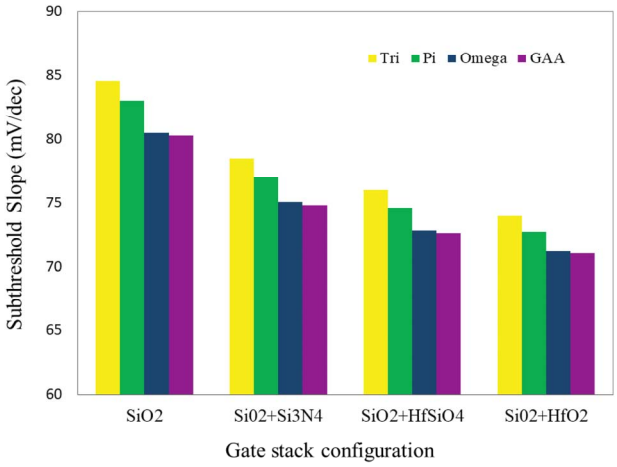

Fig. 2. Impact of gate stack configuration on SS

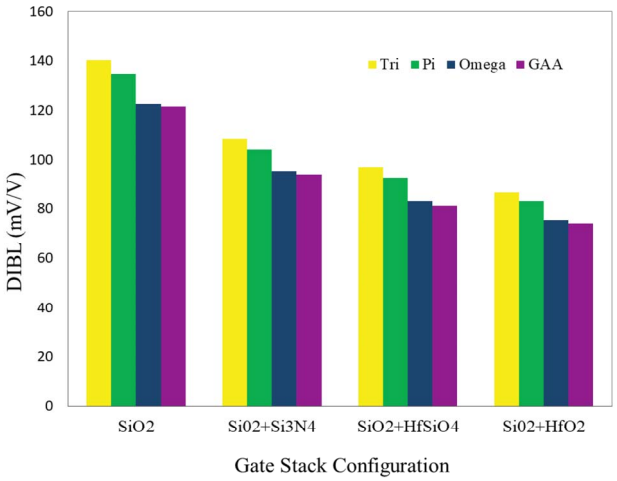

Fig. 3. Effect of gate stack configuration on DIBL

$$SS = dV_{GS} / d(\log_{10} I_{DS})$$

where V_G is the gate voltage and I_D is the drain current. For a FinFET device, an SS value of 80mV/decade means that an 80 mV change in the gate voltage will bring about a tenfold increase in the drain current.

The variation in SS for afore-mentioned FinFET structures is shown in Fig. 2 the value of SS is higher for FinFET devices using only SiO_2 for gate dielectric, with the SS being 84.54 mV/dec, 83 mV/dec, 80.44 mV/dec and 80.26 mV/dec for Tri, Pi, Omega and GAA FinFET respectively. However, for structures using high-k dielectric, the value of SS is significantly reduced, with Hafnium Oxide and Silicon Oxide stack exhibiting better SS than other configurations. The use of HfO_2 as gate dielectric yields the SS value of 74 mV/dec for Tri gate, 72.76 mv/dec for Pi gate, 71.2 mV/dec for Omega and 70.99 mV/dec for GAA FinFET. Furthermore, due to enhanced electrostatic control, in GAA FinFET, leakage current is abated and hence, SS is lower than other three multigate structures discussed.

Drain Induced Barrier Lowering (DIBL) is one of the short channel effects that arises as a result of channel length reduction. It is defined as the decline in potential barrier with the increase of drain bias. DIBL is expressed by the equation as in [13]:

$$DIBL\ (mV/V) = \Delta V_{TH} / \Delta V_{DS}$$

Fig.3 shows the DIBL of multigate FinFET devices with varying gate stacks. The DIBL follows a downward trend as we shift from SiO_2 to high-k dielectric gate stacks, with the DIBL ranging from 140.25 mV/V for SiO_2 to 86.84 mV/V for Hafnium Oxide stack considering Tri gate FinFET. GAA FinFET along with HfO_2 gate stack provides an even better result, suppressing DIBL to 74.24 mV/V.

From both fig. 2 and fig. 3 it is evident that higher relative permittivity of the high-k layer in the gate oxide stack results in enhanced DIBL and Subthreshold Slope.

B. Impact on current, off current and I_{on}/I_{off} ratio

The on current (I_{on}) and off current (I_{off}) are major device electrical parameters to estimate the device performance, especially switching speed of the circuit and standby time. In order to achieve robust switching performance, I_{on} is required to be higher and I_{off} should be as close to zero as possible, meaning a high I_{on}/I_{off} ratio.

But in short channel transistors, the prevalence of high leakage current hinders switching performance by reducing the I_{on}/I_{off} ratio. Use of multigate structure together with high-k dielectric proves to mitigate the problem and demonstrates superior switching behavior [14].

The on-state current is defined as the drain current at which gate voltage (V_{GS}) equals the drain voltage (V_{DS}). In this work I_{on} is measured at $V_{DS} = 0.1V$. Fg.4 shows the fluctuation in I_{on} when the gate oxide stack is altered. FinFETs with SiO_2 as gate dielectric does not indicate significant on current. But, substituting SiO_2 with high-k dielectric stack exhibits a gradual increase in on current. The best value of I_{on} is observed with GAA FinFET having HfO_2-SiO_2 stack. The mobility degradation is a serious issue when the high-k dielectrics are used instead of conventional gate oxide SiO_2 and which is due to Remote Coulomb Scattering (RCS), Remote Phonon Scattering (RPS) [15]. The net mobility of GS high-k dielectric depends on thickness, a dielectric constant of Interfacial-Layer

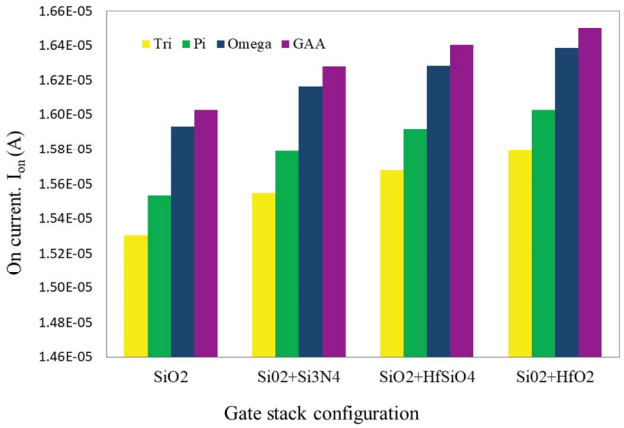

Fig. 4. Effect of gate stack configuration on I_{on}

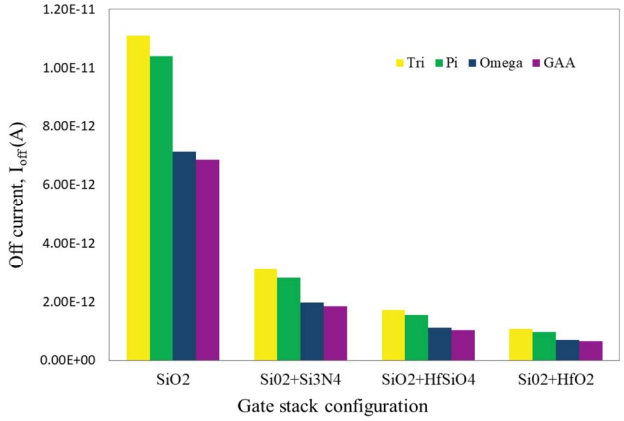

Fig. 5. Effect of gate stack configuration on I_{off}

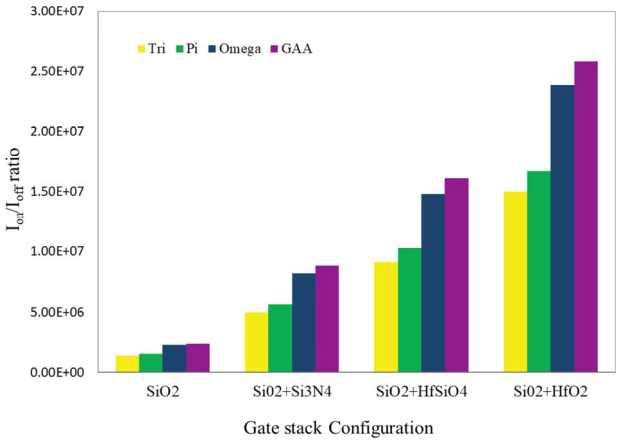

Fig. 6. Effect of gate stack configuration on I_{on}/I_{off} ratio

(IL) and of high-k. The mobility reduced due to coupling between the charges and channel (increased RCS and RPS) when the dielectric constant of IL increase [16]. In high-k FinFETs, increased relative permittivity increases the fringing field, which, in turn, reduces scattering. As a result, mobility is enhanced, making it possible to observe improved I_{on} even at 8nm channel length [17].

On the other hand, off current is the current that flows in the absence of gate voltage (V_{GS} = 0V). FinFETs with SiO_2 as dielectric, as shown in fig. 5, demonstrates I_{off} as high as in the range of 10^{-11}. The alteration in the dielectric shows a drastic reduction in I_{off}, with I_{off} in the range of 10^{-13} for HfO_2 stack.

In Fig. 6, the change in I_{on}/I_{off} ratio in accordance with the gate oxide stack variation is shown. The figure represents an overall upward trend as oxide stack with higher relative permittivity (k) is used. The I_{on}/I_{off} ratio is in the order of 10^6 when SiO_2 is used as dielectric in multigate FinFET devices. For Si_3N_4 and $HfSiO_4$ gate stack, I_{on}/I_{off} ratio increases exponentially. The I_{on}/I_{off} current ratio reaches the order of 10^7 when HfO2 oxide stack is used. GAA FinFETs, with ultimate control over the channel region, provides improved I_{on}/I_{off} ratio than other multigate FinFETs.

IV. Conclusion

A 3D simulation analysis of multigate FinFETs with high-k stack oxide is performed. From the simulation it is observed that, high-k stack oxide shows reduced short channel effects, lower leakage current, improved SS and higher I_{on}/I_{off} ratio than SiO_2. Also, gate stacks having dielectric with higher relative permittivity (k) exhibit better short channel effect suppression. It is also found that, GAA FinFET indicates enhanced performance than Tri gate, pi gate and Omega gate FinFETs.

***Abstract*—As a perovskite material, methylammonium lead iodide has become more popular for its flexibility, low-cost, lightweight, thin film and high power conversion capability in photovoltaic research community. In this work, we have explored the effect of solar concentration on PV performance for methylammonium lead iodide ($CH_3NH_3PbI_3$) perovskite solar cell computationally. To calculate the band structure, bandgap and density of states (DOS) of $CH_3NH_3PbI_3$, density functional theory (DFT) is used here. The detailed balance method is employed to figure out the effect of concentration on performance of perovskite solar cell. We have calculated performance parameters of $CH_3NH_3PbI_3$ solar cell for two solar spectra AM 1.5 G and AM 1.5 D. All calculations have been performed at different solar concentrations ranging from no concentration to full concentration for both types solar spectra. It is found that the solar cell efficiency at 1.5 G spectrum is higher than 1.5 D solar spectrum at any solar concentration. These results may impact future research on perovskite solar cell.**

Keywords—Perovskite solar cell (PSC), solar concentration, detailed balance limit, density functional theory (DFT), PCE.

I. INTRODUCTION

The worldwide average energy utilization rate is augmenting. It has been found that a daily solar radiation approximately 2×10^{17} W incident on earth at sea level is 12500 times over than the average global power consumption in 2006 [1]. It indicates the immense potential of solar energy to deliver the energy demand of the world. With the rapid usage of conventional energy, the world climate is being hampered tremendously. Hence we are to search for environment friendly sources of energy. Solar energy is abundant and it creates no harmful effect to the environment. Solar cell is the most efficient device to utilize the energy of the sun. Scientists are working on solar cells and trying to increase their efficiencies by using different types of materials. For perovskite materials, the efficiencies of solar cell have increased from 3.8% in 2009 [2] to 23.3% in late 2018 [3, 4]. Methylammonium lead tri-iodide ($CH_3NH_3PbI_3$) perovskite solar cells have unique features such as direct bandgap, lightweight, thin and flexibility, low cost of raw materials and low fabrication cost, high absorption coefficient, high efficiency [5-9]. These are very amazing in the field of solar cell research.

At present researchers are thinking of third generation photovoltaic cell due to efficiency limit. Perovskite solar cell is in the third generation category. The highest experimental efficiency of $CH_3NH_3PbI_3$ solar cell is 19.3% [10]. For a single-bandgap material, the detailed balance efficiency is 31% with no concentration (i.e. 1 sun) [11] for bandgap of 1.31 eV and 41% with full concentration (i.e.46,198 suns) [12] for bandgap of 1.1 eV. The AM 1.5 G and AM 1.5 D spectra have been considered in this work. The AM 1.5 D spectrum accounts for solar radiation as it is received directly from the sun after experiencing loss through the atmosphere. The AM 1.5 G spectrum adds extra solar radiance to the AM 1.5 D spectrum to account for additional light received from a 2π steradian field of view due to Rayleigh scattering.

Density functional theory (DFT) has been used in this research to find out the electronic properties of methylammonium lead iodide ($CH_3NH_3PbI_3$). We have found bangap of 1.65 eV for this organometal lead trihalide. The detailed balance efficiency according to SQ model [11] has been calculated to get maximum possible efficiency. The PCE (Power Conversion Efficiency) is 32.01% for experimental value, 29.87% for calculated value at AM 1.5 G and 31.17% for experimental value, 28.81% for calculated value at AM 1.5 D under no concentration. Under full concentration, the power conversion efficiency (PCE) is 39.86% for experimental value, 36.40% for calculated value at AM 1.5 G and 38.84% for experimental value, 35.13% for calculated value at AM 1.5 D.

II. SIMULATION MODEL

A. Detailed Balance Model

To calculate efficiency of solar cells many types of models are used by PV researchers. In this study, detailed balance limit according to Shockley Queisser model [11] has been adopted to estimate the best possible efficiency for the organometal lead iodide- $CH_3NH_3PbI_3$. The SQ model assumptions including ideal condition are as follow:

- 6000 K and 300 K are the sun and solar cell temperature respectively.
- No overlapping in inter band transition.
- Between two bands there must be radiative recombination.
- Carriers with infinite mobilities are extracted from VB or CB.

The current-voltage characteristic for single gap solar cell is given by

$$I(V) = q[Xf_s\varphi(E_g,\infty,T_s,0)+(f_c - Xf_s)\varphi(E_g,\infty,T_c,0) - f_c\varphi(E_g,\infty,T_c,qV)] \quad (1)$$

where E is energy, X is solar concentration, q is electron charge, T_s and T_c are the sun and solar cell temperature

respectively and, f_s and f_c are the sun and solar cell geometrical factors respectively. For ideal behaviour of cell, the photon flux expression [13] is represented as

$$\varphi(E_l, E_h, \mu, T) = \frac{2\pi}{h^3 c^2} \int_{E_l}^{E_h} \frac{E^2}{\exp(^{E-\mu}/_{kT}) - 1} dE \qquad (2)$$

where, k is Boltzmann's constant, μ is chemical potential, c is the speed of light and h is Planck's constant. So the PCE (power conversion efficiency) is found by

$$PCE = \frac{V.I(V)}{X.P_{in}} \qquad (3)$$

where P_{in} is given by

$$P_{in} = q \int_0^{\infty} E \left(\frac{2\pi q^3}{h^3 c^2} \right) \frac{E^2}{\exp(^{E}/_{kT}) - 1} dE \qquad (4)$$

We have calculated the PCE for $CH_3NH_3PbI_3$ solar cell using this equation.

B. DFT Calculation

DFT is a computational technique of obtaining an approximate solution to the Schrodinger equation of many body systems. Investigation of magnetic, structural and electronic properties of molecules, materials and defects are computed in DFT. Electron density is used to calculate one part of energy and other part of energy computation is done by a wave function in DFT method. We can find the total electron density if the squared wave function is divided by the number of electrons. Hohenburg-Kohn stated a theorem that all ground state properties of a system are determined by the density of the system [14, 15]. The total ground state energy is a functional of density of a many electron system in this case.

III. Results and Discussion

A. Band Gap and Density of states

Quantum Espresso software simulation is used for calculation of band gap and density of states (DOS) of $CH_3NH_3PbI_3$ based on DFT. We have used the so-called Generalized Gradient Approximation (GGA) to describe the exchange correlation functional. The schematic diagram of unit cell, band structure and DOS (density of states) are shown in Fig. 1, Fig. 2 and Fig. 3 respectively. The lattice constants for symmetric group of Pm are a = 6.437 Å, b = 6.439 Å and c = 6.492 Å for the monoclinic phase material $CH_3NH_3PbI_3$ at room temperature. The calculated bandgap of methylamonium lead iodide ($CH_3NH_3PbI_3$) is 1.65eV which has difference in value with the given experimental bandgap in other research [16, 17].

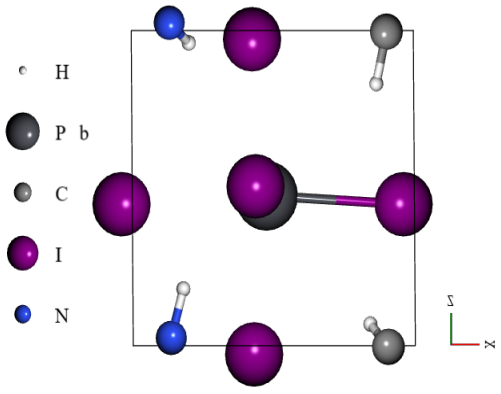

Fig. 1. Schematic diagram of methylammonium lead iodide ($CH_3NH_3PbI_3$) unit cell

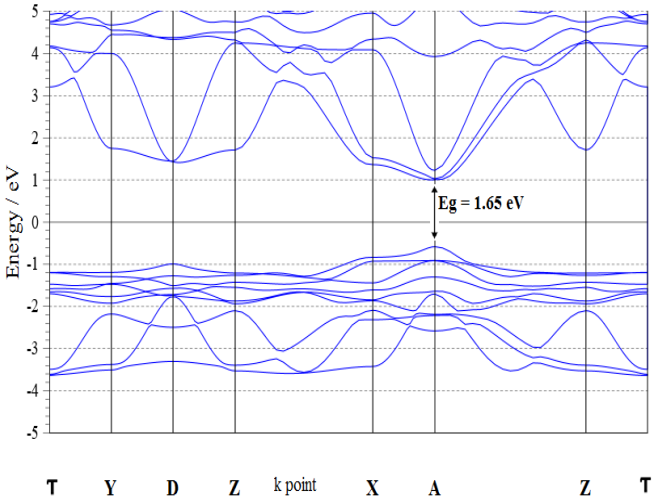

Fig. 2. Bandgap and band structure of methylammonium lead iodide ($CH_3NH_3PbI_3$).

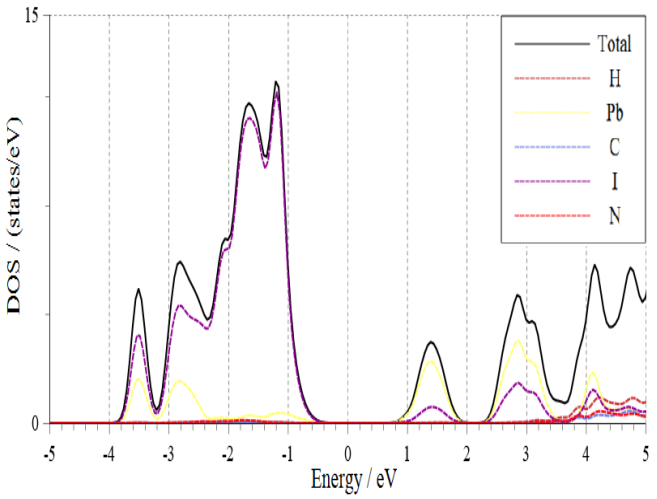

Fig. 3. Density of states (DOS) at different enrgy (eV) for methylammonium lead iodide ($CH_3NH_3PbI_3$).

B. Detailed Balance Study

The detailed balance analysis of the solar cell is performed here using the AM 1.5 D and AM 1.5 G solar spectra. The operational response of a solar cell depends on the spectrum of light that illuminates the cell. The sun is often modeled as a 6000 K blackbody. But the sun's temperature varies across the solar disc and light originating from the sun will be attenuated by the solar atmosphere that may make blackbody approximation questioned. Considering earth's atmospheric condition solar cell performances are taken at AM 1.5 solar spectrum. These effects are increased for longer optical path lengths traversed through the

atmosphere. So, the AM 1.5-Direct (AM 1.5 D) and AM 1.5-Global (AM 1.5 G) solar spectra are used for terrestrial applications [4]. These spectra are used by the photovoltaic community for terrestrial based applications.

In our calculation, we have considered the solar spectra AM 1.5 D and AM 1.5 G. The geometric parameters f_c and f_s have been defined to be equal to 1 and 2.1646×10^{-5} [18] respectively. The performance of a photovoltaic cell is shown at different solar concentration (i.e. 1 sun = No concentration to 46,198 sun = full concentration). The detailed balance performance of $CH_3NH_3PbI_3$ solar cell for experimental bandgap (E_g = 1.5 eV) and calculated bandgap (E_g = 1.65 eV) are plotted in Fig. 4 and Fig. 5 respectively as

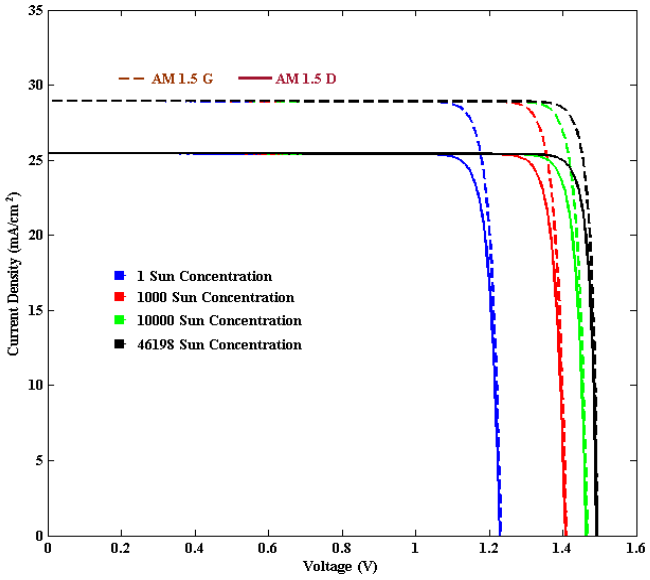

Fig. 4. I-V characteristics of single-gap perovskite (Methylammonium lead iodide, $CH_3NH_3PbI_3$) solar cell performed in detailed balance limit for experimental bandgap at different solar concentration (dotted lines and solid lines show results of Air Mass 1.5 G and Air Mass 1.5 D respectively).

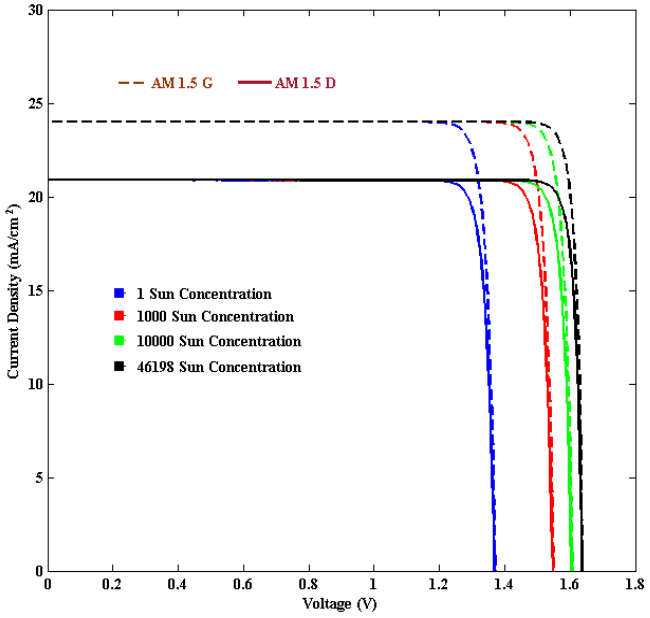

Fig. 5. I-V characteristics of single-gap perovskite (Methylammonium lead iodide, $CH_3NH_3PbI_3$) solar cell performed in detailed balance limit for calculated bandgap at different solar concentration (dotted lines and solid lines show results of Air Mass 1.5 G and Air Mass 1.5 D respectively).

TABLE I. DETAILED BALANCE EFFICIENCY OF METHYLAMMONIUM LEAD IODIDE SOLAR CELL FOR EXPERIMENTAL BANDGAP AT DIFFERENT SOLAR CONCENTRATION

Spectrum	Efficiency			
	1 sun	*800 sun*	*9000 sun*	*46198 sun*
AM 1.5 G	32.01	36.90	38.67	39.86
AM 1.5 D	31.17	35.95	37.68	38.84

TABLE II. DETAILED BALANCE EFFICIENCY OF METHYLAMMONIUM LEAD IODIDE SOLAR CELL FOR CALCULATED BANDGAP AT DIFFERENT SOLAR CONCENTRATION

Spectrum	Efficiency			
	1 sun	*800 sun*	*9000 sun*	*46198 sun*
AM 1.5 G	29.87	33.93	35.41	36.40
AM 1.5 D	28.81	32.74	34.17	35.13

a set of I-V characteristics. The experimental bandgap allows larger short-circuit current (I_{sc}) than calculated bandgap because the experimental bandgap value absorbs a larger portion of solar spectrum than calculated bandgap value. But experimental bandgap places a fundamental limit on the open-circuit voltage i.e. it has lower open circuit voltage (V_{oc}) where the calculated value has higher open circuit voltage (V_{oc}). We have used MATLAB coding for the simulation process to obtain the efficiencies, fill factors and current-voltage characteristics. The power conversion efficiency of this methylammonium lead iodide solar cell at different solar concentration for both AM 1.5 G and AM 1.5 D are tabulated in TABLE I and TABLE II respectively. The efficiencies for experimental and calculated bandgap for different solar concentrations are shown in Fig. 6 and Fig. 7 respectively. All values are plotted based on detailed balance efficiency limit from 1 sun concentration (no concentration) to 46,198 sun concentration (full concentration). The solar cell efficiency

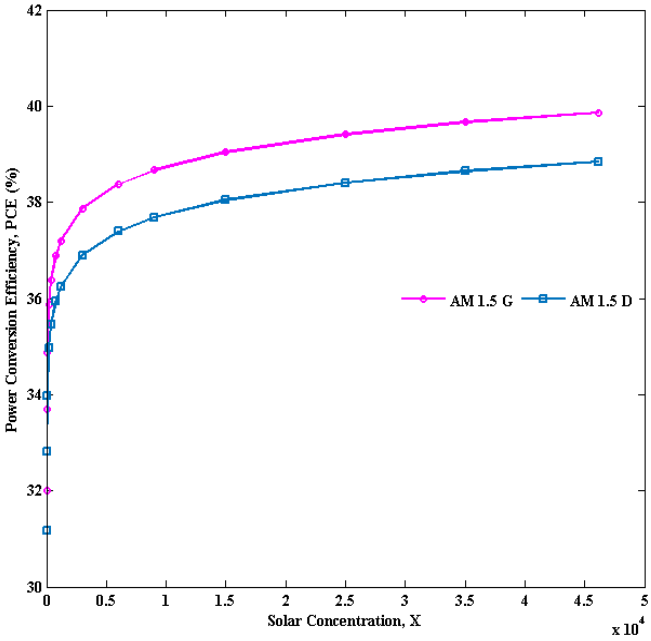

Fig. 6. Power conversion efficiency (PCE) of a single-gap perovskite (Methylammonium lead iodide, $CH_3NH_3PbI_3$) solar cell with different solar concentration at experimental bandgap for both AM 1.5 G and AM 1.5 D.

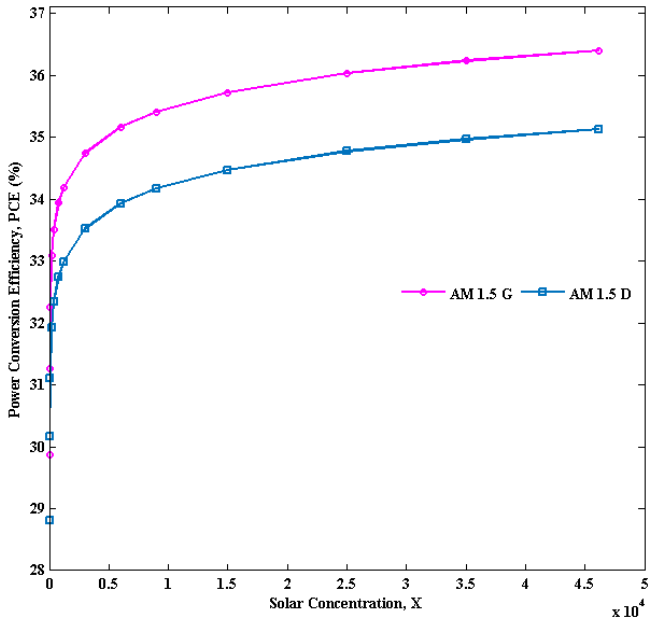

Fig. 7. Power conversion efficiency (PCE) of a single-gap perovskite (Methylammonium lead iodide, $CH_3NH_3PbI_3$) solar cell with different solar concentration at calculated bandgap for both AM 1.5 G and AM 1.5 D.

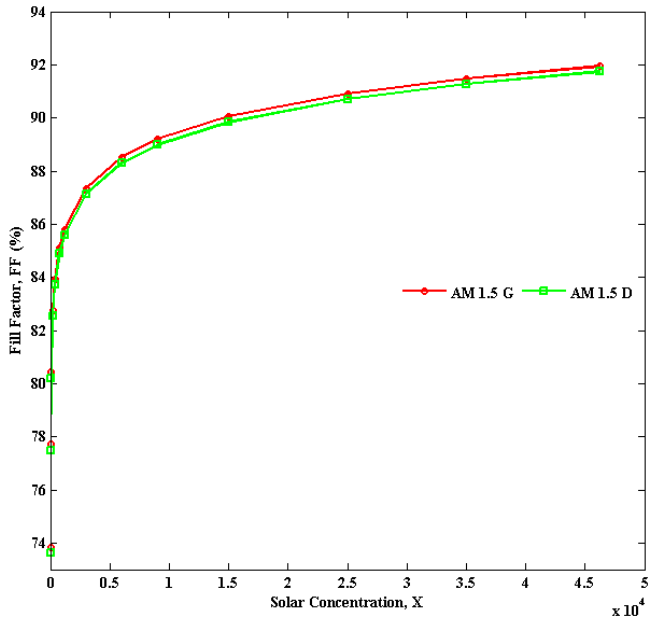

Fig. 8. Fill factor of a single-gap perovskite (Methylammonium lead iodide, $CH_3NH_3PbI_3$) solar cell with different solar concentration at experimental bandgap for both AM 1.5 D and AM 1.5 G.

increases with solar concentration where highest concentration shows highest value of solar cell efficiency. For the experimental bandgap (E_g = 1.5 eV), the maximum obtained efficiency is 39.86% for AM 1.5 G and 38.84% for AM 1.5 D. For the calculated bandgap (E_g = 1.65 eV), we have found the maximum efficiency 36.40% for AM 1.5 G and 35.13% for AM 1.5 D. The fill factors at different solar concentrations are shown in Fig. 8 and Fig. 9 for experimental and calculated bandgap respectively. The AM 1.5 G and AM 1.5 D give approximately same values of fill factor at different concentrations. We have evaluated the fill factors as a function of solar concentration for both experimental and calculated bandgap. Under no concentration, the fill factors are 73.83%, 75.45% for experimental and calculated bandgap respectively at AM 1.5 G. Under no concentration, fill factors are 73.61 %, 75.23 % for experimental and calculated bandgap respectively at AM 1.5 D. Under full concentration fill factors are 91.94% and 91.96% for experimental and calculated bandgap respectively for AM 1.5 G. Under full concentration fill factors are 91.73% and 91.74% for experimental and calculated bandgap respectively for AM 1.5 D. The improvement in cell performance is given by increment of fill factors. Methylammonium lead iodide ($CH_3NH_3PbI_3$) solar cell gives high fill factors for both solar spectra. The fill factors are increased with increasing of solar concentration.

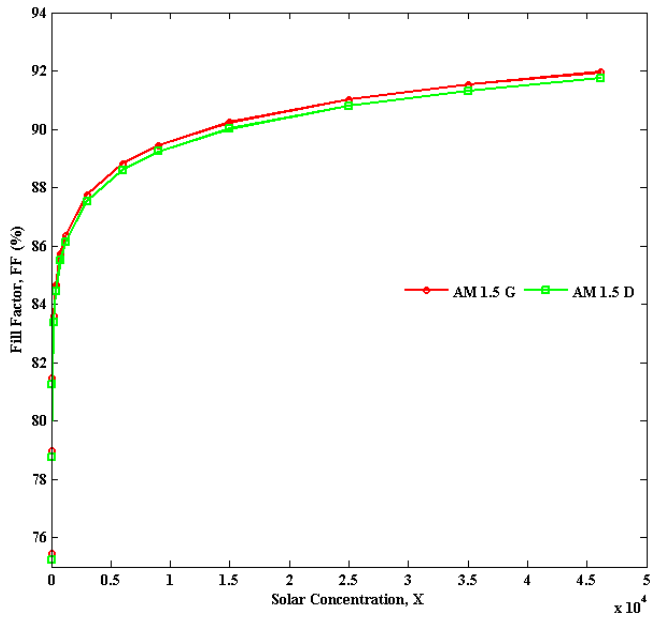

Fig. 9. Fill factor of a single-gap perovskite (Methylammonium lead iodide, $CH_3NH_3PbI_3$) solar cell with different solar concentration at calculated bandgap for both AM 1.5 G and AM 1.5 D.

IV. Conclusion

In this work, we have probed the effects of solar concentration on different cell performance parameters. The DFT method is used to calculate the bandgap, band structure and density of states of methylammonium lead iodide perovskite. Detailed balance method is employed to calculate efficiency of $CH_3NH_3PbI_3$ solar cell. We have performed our investigations for both AM 1.5 G and AM 1.5 D conditions. We have obtained the optimum possible efficiency for the bandgap. It is found that the AM 1.5 G solar spectrum produces better efficiency compared to AM 1.5 D. Our results will be fruitful for further research in $CH_3NH_3PbI_3$ photovoltaics.

***Abstract*—Single phase dual active bridge (DAB) dc-dc converter is an ambitious candidate for the fast charger technology of the electrified vehicles. It has two dc-ac converter connected back to back through a bridge inductor isolated by a transformer. In particular, this paper presents the semiconductor loss calculation and the efficiency of the converter considering two different models and zero voltage switching (ZVS) switching. It also shows the optimal frequency range of $20\ kHz$ to $70\ kHz$ for the highest efficiency above 97% at different power level of operation between $124 - 35\ kW$. Finally, the study recommends a suitable cooling arrangement for the fast charger station to keep the junction temperature within the permissible limit. The simulation results confirm theoretical values.**

***Index Terms*—single phase DAB, dc-dc converter, semiconductor loss, fast charger station, efficiency of DAB, switching frequency of DAB**

I. Introduction

The modern world is moving towards electric vehicle solution from conventional one for sustainable transportation, reduced traditional consumption of fuel to lessen emission, and to reduce environmental pollution reported in [1] and [2].

One of the significant problems in an electric vehicle is its short driving range due to the lack of battery capacity, inadequate charging infrastructure and long charging time evaluated in [10].

Reducing charging time or fast charging of vehicle technology requires a high power charger. Increasing the power level increases the size of the charger. Hence, reduced size, compact design, and fast charging technology can be achieved by high power and high switching frequency application. High power silicon carbide (SiC) module makes it achievable to get the high-frequency operation that reduced the size of the components of the charger for a compact design. On the contrary, high switching frequency causes high switching and conduction loss and affects the efficiency of the system mentioned in [3] and [4].

Several control schemes, described in [11] - [14], suggest the possibility to control the dc-link voltage at the desired level. Besides, current SiC power module, detailed in [5], makes it possible of high voltage application up to 1.7 kV shown in [15] and [16]. It is also mentioned in [16] that maximum efficiency happens at an operating power level lower than the rated power level of the converter for high voltage high-frequency application. For example, it informed about 98.7% efficiency for 40 kW operation without the inclusion of auxiliary power loss of the converter designed for 100 kW of rated power. Furthermore, in [7] and [8], different DAB models have been proposed to estimate the current for loss calculation. Hence, it is required to find a suitable DAB model for loss calculation of high power, high voltage and high-frequency application needed for todays fast charging application with a frequency range of efficient operation.

In this paper, the semiconductor losses of a 100 kW dc-dc converter and it's efficiency are calculated in details considering the two different models of single-phase DAB converter. Based on the result, the optimal switching frequency range has been determined to reach the highest efficiency at different power levels. Finally, the maximum junction temperature is investigated for determining heat sink requirement.

II. Essential Parameters For Semiconductor Losses

Conduction and switching losses are the two losses contribute to the semiconductor losses. Accurate estimation of these losses is fundamental to find the heat source as a power loss that causes the rise of the junction temperature of the semiconductor devices. Conduction loss is approximated according to

$$P_c = V_f I_{avg} + R_{on} I_{rms}^2 \tag{1}$$

where P_c, V_f, R_{on}, I_{avg}, I_{rms} indicate conduction loss, forward voltage drop, on-state resistance, average current, and RMS current respectively. Similarly, switching loss is calculated according to

$$P_s = f_s \left(E_{on} + E_{off}\right) \tag{2}$$

$$E_{on} = E'_{on} \left(\frac{I_s}{I'_s}\right)^{K_{I,on}} \left(\frac{V_s}{V'_s}\right)^{K_{V,on}} \tag{2a}$$

$$E_{off} = E'_{off} \left(\frac{I_s}{I'_s}\right)^{K_{I,off}} \left(\frac{V_s}{V'_s}\right)^{K_{V,off}} \tag{2b}$$

where P_s, E, f_s, V, I, K_V, K_I stand for switching loss, switching energy, switching frequency, switching voltage, switching current, voltage coefficient, and current coefficient respectively. E', V', and I' indicate the corresponding datasheet value of the power module in [5].

A. Parameters for Switching loss

The necessary switching loss parameters are f_s, selected based on application and device requirement, E_{on} and E_{off} calculated or estimated from the datasheet. E'_{on}, E'_{off}, V'_s, and I'_s are collected from device datasheet [5]. K_V and K_I are estimated by using some selected values of Vs and Is from the voltage-current plot of the device from the datasheet [5].

B. Parameters for Conduction loss

The datasheet parameters for the conduction loss calculation are V_f and Ron whereas V_f could be a fixed value or zero according to the modern device manufacturer. I_{avg} and I_{rms} are the currents depend on the topology of the circuit and the operating point of the application specific design. Mathematical techniques could be used to find the required average and RMS current for calculating conduction loss of the switch.

III. Mathematical Models Of Single Phase Dual Active Bridge Converter

The single phase dual active bridge (DAB) converter is a dc-dc converter uses for many application especially for the recent technology of e-mobility shown in Fig. 1. The input voltage, $V1$ is controlled constant using VSC based rectifier [6], and the output voltage, $V2$ is controlled at a specific ranges of voltages value based on the particular application. There are two half-bridge legs on each side of the isolating transformer, and an inductor, L with a leakage resistance, bridges them both. Each leg consists of two switches, and each switch contains one MOSFET and one antiparallel DIODE in it. The inductor, L could be leakage inductance of the transformer or a separate one.

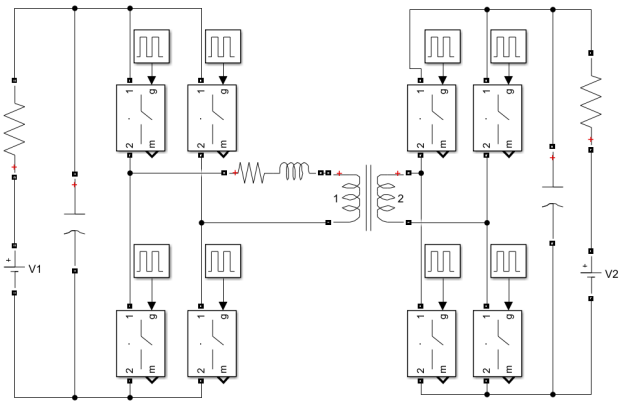

Fig. 1. Single phase dual active bridge dc-dc converter.

In Fig. 2, single phase DAB is modelled. The left terminal voltage of the bridge is V_{ac1}, which is equal to $V1$ or $-V1$ or $zero$ depending on the connection and combination of switches. Similarly, the right terminal voltage of the bridge is V_{ac2}, which is equal to $nV2$ or $-nV2$ or $zero$. n refers to the turn ratio of the transformer. Figure 3 shows the voltage and current of the inductor for unity turn ratio and equal terminal voltage of the DAB.

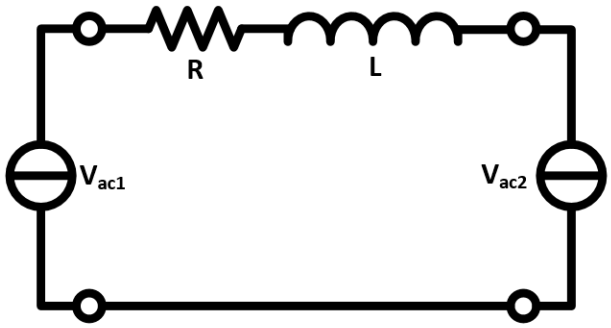

Fig. 2. Mathematical model of single phase DAB where $R = 0$ presents DAB loss-less (DAB-LL) model and $R \neq 0$ presents DAB conduction loss (DAB-CL) model.

Hence, the DAB model presented in Fig. 2 modelled two voltage sources at the inductor terminal along with inductor and resistor connected in series. Here amplitude of V_{ac1} = $V1$ and V_{ac2} = $nV2$. Value of L is selected in a way to be able to supply the maximum current to the load. R includes the on-state resistance of two switches in conduction, the leakage resistance of the inductor, and the resistance of the transformer. Based on the value of R whether it is $zero$ or non $zero$, the model in Figure 2 can be considered as DAB Loss-less (DAB LL) model and DAB conduction loss (DAB CL) model respectively [7]. These models are used to estimate the switching current, average and RMS current values for estimating semiconductor loss of DAB.

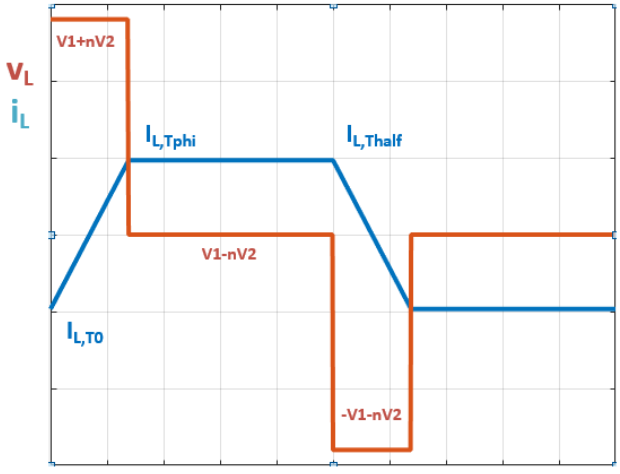

Fig. 3. Voltage and current of the DAB

A. DAB-LL Model

If $R = 0$ is considered then the DAB model in Fig. 2 becomes DAB-LL model. This model is useful to get the maximum possible stress value of the current for selection of the switches of the converter. The principal current equation for this model is described as

$$i_L(t) = \begin{cases} i_L(T_0) + \frac{M}{L}(t - T_0); & T_0 \le t \le T_\phi \\ i_L(T_\phi) + \frac{N}{L}(t - T_\phi) & T_\phi \le t \le T_{\frac{1}{2}} \end{cases} \quad (3)$$

where $M = V1 + nV2$, $N = V1 - nV2$, $T_0 = 0$, T_{phi} is the time of the phase shift which is about 49 degree for $100\ kW$ system in this study. This equation (3) is used for getting the switching currents and the conduction currents of the switches.

B. DAB CL Model

When $R \neq 0$, the DAB model in Fig. 2 becomes DAB-CL model and $R = 2Ron + R_L + R_{tr1} + n^2 R_{tr2}$. The base current equation, in this case, is derived as

$$i_L(t) = \begin{cases} e^{\frac{-t}{\tau}} i_L(T_0) + \frac{M}{R}(1 - e^{\frac{-t}{\tau}}); & T_0 < t < T_\phi \\ e^{\frac{-t+T_\phi}{\tau}} i_L(T_\phi) + \frac{N}{R}(1 - e^{\frac{-t+T_\phi}{\tau}}); & T_\phi < t < T_{\frac{1}{2}} \end{cases} \quad (4)$$

where $\tau = \frac{L}{R}$. This equation (4) gives the switching currents and the conduction currents for the semiconductor loss calculation for DAB-CL model.

The power in and power out of the DAB can be calculated using (5) and (6) below along with the related current from (3) and (4).

$$Pin = \frac{2V1}{T_s} \int_0^{\frac{T_s}{2}} i_L(t)dt \quad (5)$$

$$Pout = \frac{2V2}{T_s} \int_{\frac{T_s}{2}}^{T_s} i_L(t)dt. \quad (6)$$

IV. Derivation Of Required Current Equations

There are two switching techniques might be happened during the operation of the DAB converter known as soft switching and the hard switching. During soft switching, the current through the switch becomes zero before the turn-on of the switch because of the conduction of the anti-parallel diode. Neither voltage nor current become zero during hard switching. In the operation of the DAB converter, as long as there is a good control for the switching circuit, soft switching is evident, and hard switching is rare. Nevertheless, hard switching is considered to get the worst case possible power loss for the semiconductor device. It would be useful for the thermal analysis of many applications of DAB converter [9].

For the DAB-LL model, the switching currents to calculate the switching losses are listed below:

$$I_{L,T0} = \frac{-\pi N - 2\phi nV2}{4\pi f_s L} \quad (7)$$

$$I_{L,Tphi} = I_{L,T0} + \frac{M}{L} T_\phi \quad (8)$$

$$I_{L,Thalf} = I_{L,Tphi} + \frac{N}{L}\left(T_{\frac{1}{2}} - T_\phi\right) \quad (9)$$

For the DAB-CL model, the switching current equations are used for calculating switching losess as follows:

$$I_{L,T0} = \frac{-I_{L,T_{half}(I_{L,T0}=0)}}{1 + e^{(\frac{-T_{phi}+T_0}{\tau})} e^{(\frac{-T_{half}}{\tau})}} \quad (10)$$

$$I_{L,T_{phi}} = e^{(\frac{-T_\Phi}{\tau})} I_{L,T0} + \frac{M}{R}(1 - e^{(\frac{-T_\phi}{\tau})}) \quad (11)$$

$$I_{L,T_{half}} = e^{(\frac{-\frac{T}{2}-T_\phi}{\tau})} I_{L,T_{phi}} + \frac{N}{R}(1 - e^{(\frac{-\frac{T}{2}-T_\phi}{\tau})}) \quad (12)$$

where

$$I_{L,T_{half}(I_{L,T0}=0)} = e^{-\frac{T}{2\tau}} I_{L,T_{phi}(I_{L,T0}=0)} + \frac{N}{R}\left(1 - e^{-\frac{T}{2\tau}}\right) \quad (13)$$

and

$$I_{L,T_{phi}(I_{L,T0}=0)} = \frac{M}{R}(1 - exp(\frac{-T1}{\tau})) \quad (14)$$

The average and RMS current can be calculated using the piece-wise linear integration method. The integration of the current equation for a specific model would be done for the calculation of average value of the conduction current using the general equation below for a particular limit as:

$$I_{ab}(AVG) = \int_a^b i_L(t)\, dt \quad (15)$$

where a is the conduction start time of the switch and b is the conduction stop time of the switch.

The square integration of the current equation is done to find the RMS value of the current for loss calculation using equation below:

$$I_{ab}(RMS) = \int_a^b i_L^2(t)\, dt \quad (16)$$

Hence, the average and RMS value of the conduction currents for specific limits can easily be calculated according to:

$$I_{avg} = \frac{1}{T_s} I_{ab}(AVG) \quad (17)$$

$$I_{rms} = \sqrt{\frac{1}{T_s} I_{ab}(RMS)} \quad (18)$$

The switching currents, average currents, and RMS currents are calculated for the DAB-LL and DAB-CL models separately using corresponding current equations described earlier for the calculation of semiconductor losses of the DAB converter.

V. Results

The operating point considered for the converter to calculate the losses are as below:

$V1 = 700V$, $V2 = 700V$,

$I_o = 140A$, $P_o = 100kW$, and $f_s = 25kHz$.

The semiconductor device used is CREE (CAS300M17BM2) and its datasheet parameters for switching loss calculation are below:

TABLE I
PARAMETERS OF SWITCHING LOSS CALCULATION

Parmeters	Datasheet values	CREE (CAS300M17BM2)
E'_{on}	Turn-on Switching Energy (mJ)	13
E'_{off}	Turn-off Switching Energy (mJ)	10
V'_s	switching voltage (V)	900
I'_s	switching current (A)	300
$K_{V,on}$	Turn-on voltage coefficient	1.83
$K_{I,on}$	Turn-on current coefficient	0.647
$K_{V,off}$	Turn-off voltage coefficient	1.17
$K_{I,off}$	Turn-off current coefficient	1.26

The conduction loss parameters from data-sheet are forward voltage drop, V_f which is equal to zero for the chosen power module and the on-state resistance, R_{on} which is typically $8m\Omega$. Taking the variation of junction temperature into account, on-state resistance is considered as $12m\Omega$ for the maximum junction temperature of about 100 to 110^0C.

TABLE II
DAB EFFICIENCY FOR $R_{ds,on} = 8\ m\Omega$

Model		$P_{sc,DAB}$ (kW)	P_{RL} (kW)	P_T (kW)	P_{aux} (kW)	Efficiency (%)
DAB-LL	HS	3.070	0.083	0.158	0.020	96.60
	SS	1.707	0.083	0.158	0.020	97.99
DAB-CL	HS	3.0795	0.083	0.159	0.020	96.62
	SS	1.7146	0.083	0.159	0.020	98.00

The result of the analysis of the semiconductor losses and others losses are tabulated in Table II and Table III for the on-state resistance of $8m\Omega$ and $12m\Omega$. Soft switching and hard switching technique are considered along with the DAB-LL and DAB-CL model for the calculation of the semiconductor losses. Efficiency calculation considers an auxiliary loss of 20 W in all cases.

TABLE III
DAB EFFICIENCY FOR $R_{ds,on} = 12\ m\Omega$

Model		$P_{sc,DAB}$ (kW)	P_{RL} (kW)	P_T (kW)	P_{aux} (kW)	Efficiency (%)
DAB-LL	HS	3.5595	0.083	0.158	0.020	96.10
	SS	1.9518	0.083	0.158	0.020	97.74
DAB-CL	HS	3.5744	0.083	0.159	0.020	96.13
	SS	1.9644	0.083	0.159	0.020	97.75

It is evident from the tables that worst-case loss happened at the DAB-CL model and hard switching case. Losses could be further increased if the operating junction temperature rises beyond 110^0C. It is because of the positive temperature effect on on-state resistance of the switch. Hence, the efficiency of the DAB converter would be in between 96% to 98% for the models and switching schemes as mentioned earlier.

DAB-CL model is the more practical model then the DAB-LL model as each practical converter has losses during the operation. Presence of snubber capacitance and sound control circuit ensures the soft switching in the converter. Therefore DAB-CL and SS (soft switching) model is chosen for the determination of switching frequency range.

Fig. 4 shows the switching frequency versus efficiency plot. Changing frequency changes the operating power level as well because of the fixed parameters, especially inductance and phase shift, of the converter circuit. Fig. 4 also depicts that switching frequency range between 20 kHz to 70 kHz deliver the efficiency more than 97.56% with a power level between 124 kW to 98 kW. The reason for decreasing efficiency with increasing frequency is of fixed inductance, and phase shift.

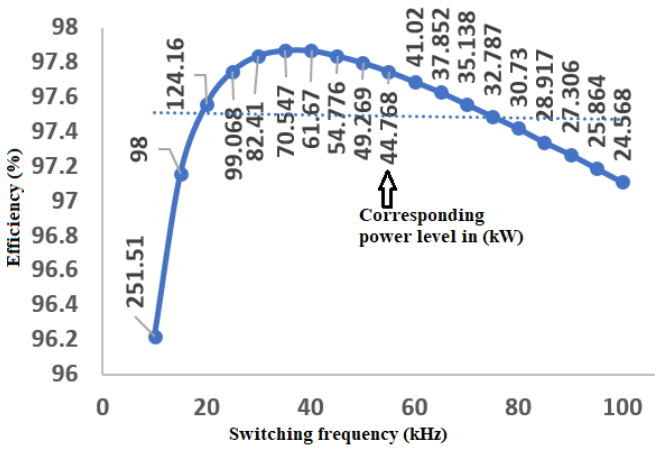

Fig. 4. Efficiency of the single phase DAB converter for different switching frequency and operating power level considering DAB-CL and SS model.

Fig. 5 shows the junction temperature for the same condition of the power level at the different switching frequencies. Junction temperature is 214^0C at 20 kHz which is 171^0C at 25 kHz, and that is about 94^0C at 70 kHz. As a result, to operate the converter at the rated power of 100 kW, there must have a heat sink to take care of the increased junction temperature.

VI. Conclusions

In this paper, semiconductor losses of the single-phase DAB converter of 100 kW are calculated for soft switching and hard switching scheme along with two models known as DAB-LL and DAB-CL models. It can be concluded from the analysis that higher operating junction temperature which raises the on-state resistance, and higher switching frequency causes higher semiconductor losses. The semiconductor losses have happened more for hard switching scheme than the soft switching scheme at the rated operating point of 100 kW, and 700 V. Achieving soft switching scheme requires a complicated control circuit that leads to additional cost but improves the efficiency of the converter. For a $100kW$ system

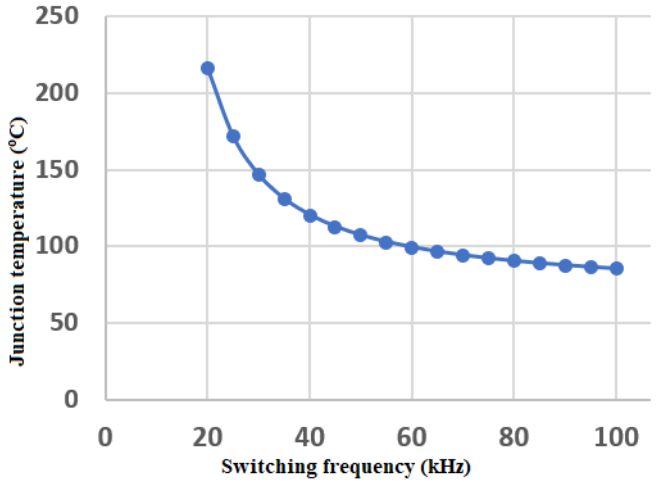

Fig. 5. Junction temperature at different switching frequency.

of DAB converter with $25kHz$ frequency, DAB-CL model soft switching scheme gives the efficiency of about $97-98\%$. On the other hand, the switching frequency can be ranged between 20 kHz to 70 kHz with a fixed phase shift angle of 49 degrees without sacrificing efficiency. However, the power level could be changed between 124 kW and 35 kW considering the on-state resistance of $12m\Omega$, junction to case thermal resistance of $0.061^oC/W$, and the maximum ambient temperature of 40^0C. Finally, at these conditions, the maximum junction temperature raises between 214 to 94^oC. Hence, a cooling arrangement must be needed for the rated operation of the converter to keep the junction temperature within the permissible limit.

***Abstract*—Land-Use detection is an important application in the context of remote sensing. This objective is to classify, a chunk of a satellite or high-earth orbit image of the earth, as the type of land-use. In this work, we have used recent advancement in computer vision with deep learning to improve the performance to the classification task. We have used a very deep convolutional neural network with the residual connection as a building block and the concept of transfer learning to train this model. The experiment shows that the performance of the classifier is very high with transfer learning on a pre-trained model rather than training from the sketch with such small dataset that is available for land use classification task. Our proposed approach generated a better result than the previously existing method in benchmark dataset.**

***Index Terms*—Convolutional Neural Network(CNN), Transfer Learning, Fine Tuning, Land-Use Classification**

I. Introduction

The land-use detection is the task of identifying what an area of land is used for. This is an important application of remote sensing. This is normally treated as a classification task. Recently few datasets are collected with a large number of labeled image of aerial photograph and many classification algorithms are used to improve the accuracy of such algorithm.

On the other hand, deep learning is an interesting and powerful development in recent years. It used the concept of neural network and backpropagation to train it to approximate any function. Convolutional neural network is the most efficient building block to deal with the image in deep learning. Recently deep learning is used for land-use classification of HSR imagery [1]. The technique such as autoencoder [2] and a variation called sparse autoencoder is used previously. Also, the deep belief network [3] was used in this context. The performance was later improved with the introduction of convolutional neural enwtork [4]–[6]. Although these models improved the performance of the application these regular convolutional neural network could not better than that as those models were not very deep. It is a common idea in deep learning that the deeper models should have better performance. But in practice, we can not just stack convolution layer on top of one another to improve the performance.

Over the year many research has proposed different variations of regular CNN to improve its performance. Recently a model called AlexNet [7] has proposed a successful deep architecture to train a big CNN on ImageNet dataset. This model is very deep and the trained with this very large dataset. One other problem with this big model is that it does not generalize well with the small dataset as these models have too many parameters to train. For this reason, a new technique called transfer learning became popular. The idea of transfer learning is to use the knowledge learned in one application in other similar applications. The transfer learning was used in land-use classification by Zhao et. al. [8]. They used the AlexNet as the base architecture and applied transfer learning on it. This shows the impressive result of this application.

Recently a new development called Residual Connection introduced by Resnet [9] has shown very impressive performance in image classification application. This uses the concept of skip connection to pass extra information to the layer. That gives the opportunity to train even deeper models without overfitting. In this work, we have explored the transfer learning technique on the residual convolutional neural network to improve the accuracy of classification of land-use.

The rest of the paper is organized as follow- Section II describes the basic of CNN, followed by our model architecture and training procedure. Section III analyses the experimental result of our proposed approach.

II. Methods

The convolutional neural network is the central building block to deal with image data with a neural network. Over the years many research has proposed various variations of the convolutional neural network to improve the performance. In the following section, we start by describing the general principles of the convolutional neural network(CNN). Then we describe the specific architecture used in our method to improve the performance of land use classification using CNN.

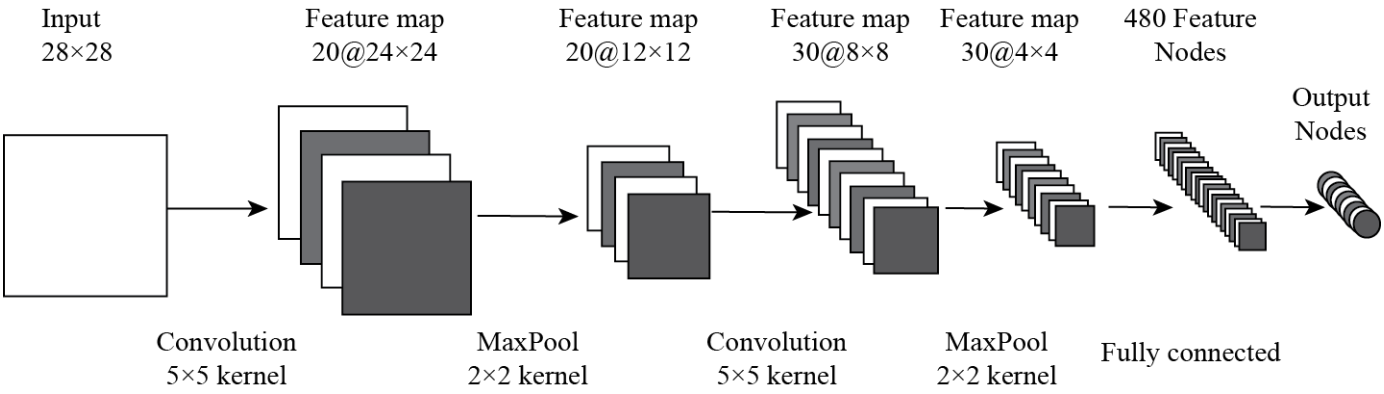

Fig. 1. An illustration of applying the convolutional neural network on a 28×28 size image.

A. Convolutional Neural Network(CNN)

The CNN [10] is a neural network based algorithm that takes an image as an input and process with learnable weights and biases to output the probability of various aspect about the image. The CNN based approach much less preprocessing on the actual image because the CNN can work with a plain image of any kind without any hand engineering. While in classical image processing the filters, that are used to processes the image is pre-defined and hand-engineered, the CNN treat the filters and learnable parameters and learn the values for those.

The kernel is basically a small size matrix that slides over the image column wise then row-wise. The step is controlled by a parameter called stride. The kernel has learnable weight. When the kernel is passed over an image the kernel weight values are multiplied with the corresponding values of the image pixels to calculate one value of the output feature map. The feature map is also a matrix which can be treated as an image but it is commonly called a feature map.

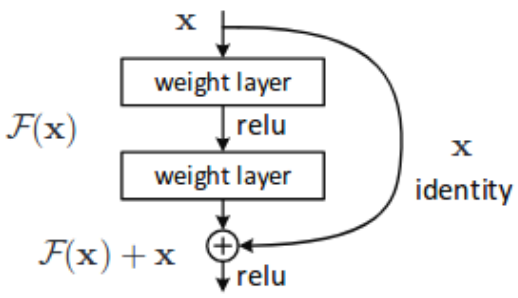

Fig. 2. A residual connection.

Another parameter of convolution is stride. The stride defines the amount of skip the kernel give for the next position. For example, with the stride size of 2, the kernel will mode 2 pixel right to generate the next pixel value in the feature map. As a result, the length of the feature map is half the size of the input length. One more parameter the determine the length of the output feature map is padding. When the kernel slide over the image, for the first position the kernel must fit the image at the corner to output the first position of the feature map. For a kernel size of 3×3, the first output of the feature map comes from the first 3 pixels. So, the feature size is 2 less than the original image for the first and last image as the kernel can not fit here. Padding defines whether to add extra dummy space in both side to keep the size of the output same as input or let the image size as it is generated by simply applying the convolution operation.

Like any other neural network, the CNN is consist of layers. The layers come on top of the previous one. The most common types of layers used in CNN are convolution layer, ReLU layer, pooling layer, and fully connected layer. The convolution layers have the kernel and the main convolution is done in this layer. Often the image size is changed in this layer. The ReLU layer is responsible for applying the nonlinearity. This is an element with activation function formulated as $max(0, x)$. The pooling layer is where the main downsampling occurs. One of the main concepts of CNN is to reduce the size of the image and finally output in some low dimensional space. The pooling layer reduces the size of the image along row and column dimension. The most common form of pooling is max pooling and average pooling. The max pooling takes the maximum values of the pixels in a given area. Finally, the fully connected layer converts the matrix into a linear vector and perform the regular linear combination as like the regular artificial neural network.

Fig. 1 shows one example of CNN on a 28×28 size image. The input size is $(28 \times 28 \times 1)$. Here 1 is the channel dimension. For a color image, it will be 3. The first convolutional layer contains the kernel of size 5×5. The output of this layer is $(24 \times 24 \times n1)$. Here n1 is the number of kernels applied in this layer. Each kernel generates one separate feature maps and all those are stacked vertically in

layer name	output size	18-layer	34-layer	50-layer	101-layer	152-layer

Fig. 3. The model architectures of different variations of ResNets.

the depth dimension. The output has depth equals the size of kernels in the previous layer. The transition from 28 to 24 is due to the kernel size of 5 with no padding. This is the input to the first max polling layer. This is a max- polling with kernel 2×2. This reduces the output size to the half of the input size. The output of this layer is $(12 \times 12 \times n1)$. Two next convolution and max-polling of the same size reduces the feature map size to $(12 \times 12 \times n2)$ to $(8 \times 8 \times n2)$. This is then passed to a fully connected layer. The next fully connected layer output the probability of all classed in the dataset.

B. Land use detection using residual CNN

The basic concept of deep learning is to use a deeper model for getting better performance. But simply adding more layer does not help at all. For an image, the application is hardly useful to add a more convolutional layer into the network. But the deeper network is required for processing high dimensional input as it contains more information. Also, a deep network has more scope for learning more complex pattern in the data. The concept of ResNet [9] introduced a novel approach for that.

Instead of learning the mapping from x to y directly with a function $H(x)$ the residual block use $F(x) = H(x) - x$. Which implies $H(x) = F(x) + x$. The residual network suggests that the mapping of residual function $F(x)$ is easier to learn than the original $H(x)$. So, the way the residual connection is made is by adding the input to a layer with the output of that layer. The intuition of such connection is that the layer can see both the transition and the change with the original input. So, the layer has more information to learn from. In practice, such a residual connection is shown to avoid vanishing gradient problem in the large neural network. This is the way the regular deep CNN model with or without residual connection has a huge difference in performance.

Fig. 2 show a residual connection. The left shows a simple forward transform. The right shows the modification to have a residual block. This connection is called skip connection

The residual connection allows very deep convolutional neural network trainable. The original paper showed the performance of deep CNN with the residual connection. It proposed 5 difference architecture with residual connection, namely Resnet-18, Resnet-34, Resnet-50, Resnet-101, Resnet-152. The number after all the model is the number of layers in the model.

Fig. 3 shows the model architectures of all the ResNet variations. All the model contains the same kind of model structure with a variation in the number of repetition of the same layer.

In this work, we have used the residual neural network as a building block for our classifier. But instead of training the model from the scratch we have used the concept of transfer learining [11], [12]. Transfer learning is the concept of using the knowledge learned in one application in some other application. This is a useful application for dealing with large CNN. As a large network contains a lot of parameters, training the entire network from sketch requires a lot of data. For many application, such a huge amount of data is not always available. In such a case, transfer learning is a useful tool. The basic intuition of transfer learning in computer vision is that the patterns learned by the shallow(earlier) layer of CNN are basic shape or lines. These are the general idea of an image and not application specific. So the knowledge learned from facial image classification can be used in land use classification. But the features learned by the higher layers are application specific complex features.

To apply the concept of transfer learning in our application we have used pre-trained ResNet model which are trained

with large general purpose dataset called ImageNet. This is a very large dataset with 1000 classes. We have updated the final fully connected layer of this model to match our output class number which is 21 in this case. Re-training a fully trained model is called fine-tuning. In this case first, we have trained the final untrained layer. The gradually trained the pre-trained portion of the model.

III. Experiments

We have implemented the model with pytorch [13] int python. All experiments were done in NVIDIA 1060 GPU.

A. Experimental Setup

Fig. 4. Sample images from the UCM land-use dataset.

For the land use application, we have used UCM dataset [14]. The dataset contains images of 21 different classes each containing 100 images with a total of 2100 images. The classes are - agricultural, airplane, baseballdiamond, beach, building, chaparral, denseresidential, forest, freeway, golfcourse, harbor, intersection, overpass, parkinglot, mobilehomepark, runway, sparseresidential, storagetanks, mediumresidential, river, tenniscourt. The size of the images is 256×256. The image was collected from large images in the US Geological Survey National Map Urban Area image collection of various cities in the US. To train this model we have randomly split the data into 90% for training and 10% for testing. Few examples of the training data are shown in Fig. 4.

We have trained the model with the image size of 256×256 with the learning rate of 0.0005 in Adam optimizer. The Adam optimizer has two hyperparameters that control the momentum to decay the learning rate. They are called beta1 and beta2. The corresponding values are set to 0.9 and 0.999. Table I summarized the parameters of the training process.

To avoid over-fitting we have used the concept of augmentation. The idea of image augmentation is to transform the image slightly to generate a slightly new image. As a result, the model will never see the actual image twice. It helps to reduce over-fittings. The over-fitting is done by introducing a horizontal or vertical flip, rotation, translation, zooming etc. The augmentation setting for our experiment is summarized in the table. II

TABLE I
Values of Training Parameters

Parameters	Values
Image input size	256×256
Optimizer	Adam
Adam: beta1	0.5
Adam: beta2	0.999
Epochs	20
Batch size	16
Learning rate	0.0005
LR Decay rate	0.99

TABLE II
Values of Augmentation Applied to the Training Image

Type of Augmentation	Values
Rotation	-45° to 45°
Horizontal Flip	Yes
Scaling factor	×1.1

B. Result Analysis

As mentioned in the method, we have conducted an experiment on five different model architecture.

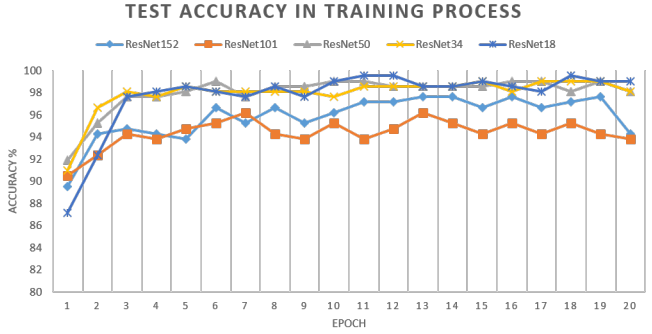

Fig. 5. Accuracy as a measurement in training process in all models.

Figure 5 shows the convergence of accuracy during training on all these model.

To further analyze the result we have reported the result in average precision, recall and accuracy of all model. Precision value for a class is the ratio of the total correctly classified image of that class and total output labeling as that class. Whereas the recall is the ratio of total correctly classifier image of that class and total images of that class. The reported precision and the recall is the average overall class. The accuracy is the overall accuracy of that model. Fig. 6 shows the result.

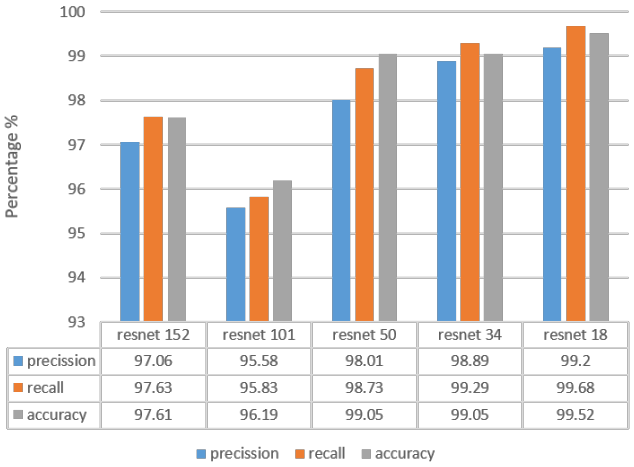

Fig. 6. Precision, Recall and the accuracy of all models.

From the result above we see that the best result is achieved from the ResNet18. Although the largest version is ResNet152. This is the consequence of small dataset. As we have mentioned above, a small dataset cannot generalize the model rather overfit the model. The whole point of using transfer learning is to solve this problem. Still, with the pre-trained model, we can not choose the largest available model for our application because of data shortage.

Table IV shows the accuracy of each class by each model. As we can see from the table, apart from a few complex class most of the classes have 100% accuracy on the test. For example, the class 'intersection' has low accuracy because 'intersection' and the 'freeway' are both images of roads. So, the model is confused by the similarity. In most other cases the features are easily separable.

Table III shows a comparison of accuracy on UCM dataset on all previous method. To match with the experiment of all other methods we have conducted the experiment with random 90% training and 10% test dataset for 10 times. The reported accuracy is the average of 10 runs.

TABLE III
ACCURACIES OF PREVIOUS METHOD ON UCM DATASET.

Methods	Accuracy
SPCK++ [14]	77.38
SSBFC [15]	91.67
DMTM [16]	92.92
LFK [17]	91.63
CNN with overfeat feature [18]	92.4
Multiview Deep learning [4]	93.48
GBRCN [6]	94.53
CNN-FT-FULL [8]	96.67
Our proposed method	97.55

From the table III above we can conclude that our method shows clear improvement over all existant method that is used in UCM dataset.

We have also compared the accuracy of different classed with different ResNet model architecture. The result is summarized in table IV.

IV. Conclusion

In this work, we have proposed a new approach for improving the classification accuracy of an important application of land-use classification. The experiments have shown the effectiveness of our approach compared to the previous approaches. Our work will help further improvement in the field of remote sensing with computer vision.

***Abstract*—Voice classification task deals with sequential data. This is well known that this type of data is well processed by a recurrent neural network. In this work, we showed that in case of longer sequence convolutional neural network can give better accuracy. Whereas the recurrent network suffers from vanishing gradient problem even with a complex model like Long Short-Term Memory(LSTM). To illustrate the method we used pathological voice detection task. It is a type of problem in human voice caused by the internal defect in the throat and very hard to detect. In this work, we experimented with low dimension feature to compare both models rather than focusing on improving the overall accuracy.**

***Index Terms*—CNN, RNN, Voice Classification**

I. Introduction

In the throat, there are some folds of tissues named vocal folds, also known as vocal cords which are the key sources for generating sound for human through vocalization. Human voice may be tempered by different phenomena like their profession- singers, manufacturing supervisors, and some organic pathologies. These pathologies may affect the human sound system that modifies the structure of vocal folds which results in unnatural vibration sequence which may cause pathological voices [1].

Several methods could be applied to evaluate whether the voice is from a normal vocal system or pathological vocal system. Usually, the medical community uses the direct method which requires observation of vocal folds which is not so comfortable for the patients. Along with these, there are some methods like GRBAS and RBH mentioned here [2], [3], that require a direct audition of doctors. To get a better approximation using these techniques highly trained and experienced doctors are required.

A normal human being can differentiate pathology voices to some extent but we can't rely on it int etiologic procedure. Human voice carries several features which can be used to differentiate or classify the voice pathology. Here come different modern deep NNs like ANN(Artificial Neural Network) and RNN(Recurrent Neural Network) which can classify the voices based on those features. There are several ways for extracting features from voice, for instance, modulation spectra mentioned here [4] and MFCC(Mel-Frequency Cepstral Coefficients) which is described here [5].

The short term power spectrum of a particular sound is represented by MFCC in the processing of sound. It depends on LCT(cosine transform) and log power spectrum on a frequency which is scaled as Mel-Frequency. MFCCs are derived from the cepstral representation of the input voice as sound. This may help to collect important acoustic events, for example, phonemes. These MFC coefficients are actually the input features in common speech recognition [6] systems, such as models that can automatically identify numbers spoken into a device like a telephone. The basic distinction between cepstrum frequency and the Mel-frequency cepstrum is that the input sound frequencies are equally separated on a predefined scale known as Mel-scale. To extract features from MFCC we need to go through some mathematical details. Nevertheless, we can easily obtain these attributes using a python package name LibROSA. We also used this technique, described later, to extract features. We used these features as the input of ANN and RNN in our approach.

The recurrent neural network is a well-known technique for working with sequential data. But it has some drawback. With length getting longer it suffers from vanishing gradient problem and it becomes harder to train longer sequence. To solve this issue many variations of RNN is proposed. Among them long short-term memory(LSTM) and gated recurrent unit(GRU) is common. In this work, we have shown that it is comparable or sometimes better to use CNN in such application than the RNN as CNN is faster and no such vanishing gradient problem.

II. Related work

In pathology voice detection literature several methodologies studied and implemented. Zulfiqar, Ali et al. worked on speaker identification and used Mel-frequency Cepstral Coefficients for attribute collection and VQ technique for differentiating speakers [5]. Firstly, they used the MFCC technique to obtain feature vectors. Then, they used the VQ technique for detecting speakers.VQ refers to classical to

a quantization method from the field of signal processing which helps to develop a model of PDF into vectors. It turns out partitioning a massive set of array into different groups having apparently the same amount of arrays nearest to them. Every group is referred to as centroid in various clustering algorithms.

Patricia Henrquez et al. studied the effectiveness of six non-linear chaotic measures on the basis of non-linear dynamics theory to differentiate between 2 levels of voice sound: healthy and pathological [7]. They found that human voice can be expressed as non-linear time series, so, they used a non-linear system such as chaos theory and extract features from the sound system. This method has several steps, including extraction of values from mutual information function, calculating correlation among feature dimension and entropies. Here, entropy tells the amount of disorder of a system. They studied Shanon and Rnyi etropy estimator. In short, they divided their work into three portion- pre-processing, here they basically process the signal, feature extraction, and classification. For classification, they used standard NN(neural network).

Zoran Milutinovic divided the voice pathology into an organic and functional group and they focused on etiologic factors for clinics [8]. Along with these, Maria Markaki and Yannis Stylianou considered modulated spectrum for detecting pathology and classifying it [4]. This method produces a high dimension space and for reduction hey proposed SVD and a method for selecting features on the basis of correlated information between a subjective signal of the input voice and calculated attributes. After feature extraction and dimension reduction, they applied a classifier named support vector machine, and used RBF as the kernel of the classifier.

Along with these, Al-Nasheri, Ahmed, et al. worked on pathology classification using auto-correlation and entropy for feature extraction [9]. They basically worked on the improvement of attribute extraction so that they could have increased accuracy of classification.

Their working pipeline could be summarized as follows, voice sound was used as signal and they pass it through bandpass filters, then passed it through small frames, after framing they used two methods to obtain attributes i.e; auto-correlation and entropy, finally, using these attributes they classify voice signal using a support vector machine(SVM).

Alireza Afshordi Dibazar also proposed a pipeline for detecting pathological speech [10]. They also used MFC coefficients as well as pitch dynamics and modeled it by a Gaussian mixture. After that, they used a Hidden Markov Classifier(HMM). Moreover, in [11] authors also proposed Gaussian mixture models and short term cepstral features for the same work mentioned. In [12] voice pathology differentiation system is implemented on the basis of local discriminant wavelet packet, for feature selection purpose they employed GA(genetic algorithm) and used SVM (support vector machine) and RBF(Radial Basis Function) kernel for the classification task.

III. Method

In this work, we experimented on two different approaches to voice classification. The data we worked with is variable length. Traditionally recurrent neural network is a preferred method for modeling variable length data. But we also experimented on Convolutional Neural Network(CNN) which is well known for fixed length data, like an image. Here we describe the theory of the used method starting with Long Short-Term Memory(LSTM) which is a variation of the recurrent neural network we worked with. Then we describe the CNN and the specific network architecture which we experimented on.

A. Recurrent Neural Network

The recurrent neural network is a sequence processing model. The input to this model is a metric of dimension sequence length(t)$\times$ length of each sequence(d). The model is basically a single layer which is folded over time step. The same block of computation is repeated for all time step. At each time step(i) one sequence vector of length d is passed through the model which outputs a hidden state h_i and an output o_i. Fig. 1 shows the unfolding process of RNN processing. Which shows that single RNN block is unfolded over time e handle the sequence of variable length. The recurrent neural network has memory to remember information from the previous time step that gives the recurrent neural network advantage over other conventional neural networks. These are the network with loops inside of it, allowing information to persist. RNNs combines input with a state vector to produce a new state vector. This new state vector contains the information about the entire past sequence. The formula for vanilla RNN is as follow

$$h_i = tanh(W_{hh}h_{i-1} + W_{xh}x_i) \quad (1)$$

$$y_i = W_{hy}h_i \quad (2)$$

To use RNN as a building block of a classification model the sequence is converted into a vector of size d by the RNN. On top of this, a dense layer is added. The input to the dense layer is size d and the output of the dense layer is size n, where n is the number of output classes. To represent the output as a probability as softmax layer is added on top of the dense layer which represents the output into a vector whose some of all elements is 1.

With the sequence getting longer the regular RNN shows a drawback of vanishing gradient, which means the gradient cannot flow properly from very last sequence to the start sequence and the information is lost. For this reason, the vanilla RNN is not very good at modeling long sequences.

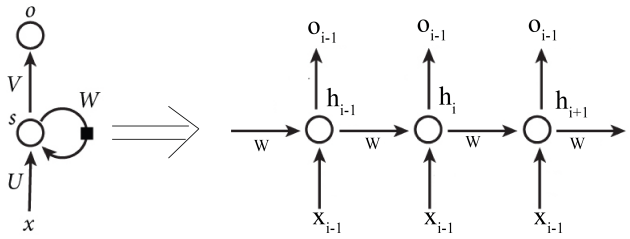

Fig. 1. Processing of sequential data in time step by unfolding a recurrent layer in the recurrent neural network. Which gives a single output for each time step that summarizes the information until that point of time. For our classification purposed we only need the last output as it summarizes the information of full sequence

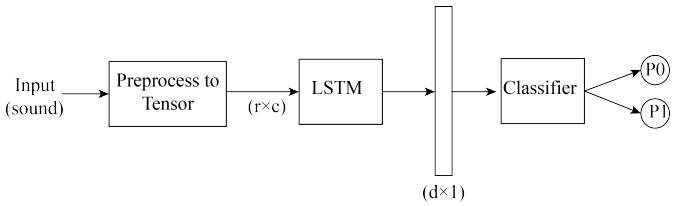

Fig. 2. RNN classifier. The input is a voice data, that is preprocessed to geenrate matrix of size (r×c) and passed through LSTM to generate vector of size $(d \times 1)$and it is the input to a classifier to generate the probability of each output classes

To solve this issue few variations of RNN were proposed. Among them LSTM [13] and GRU [14] are the two most popular model. Long short-term memory network(LSTM) is a variation of RNN, that is capable of learning long-term dependency. LSTM is ground up designed to solve long-term dependency problem. Remembering is its default behavior and it has a forget gate to forget information that is not important anymore. The full model is trained end to end. So, the model can learn that to remember and what to forget by itself. The key idea of the LSTM model is the cell state. With only some minor linear interaction the cell state flows straight through the sequence almost unchanged. One other important part of this model is the 'gate' concept. The information is added or removed from cell state carefully regulated by this gates. Formulas for updating the LSTM cell are

$$f_i = \sigma(W_f.[h_{i-1}, x_i] + b_f) \tag{3}$$

where x_t is the input and h_i is the hidden state from the previous time step $i-1$ that is passed to it. And the computed hidden state at this state will be kept in his variable to access it in the next time step.

The cell state is represented as C_i, which is responsible to calculating current output and hidden state. The cell state is updated as follow

$$I_i = \sigma(W_j.[h_{t-1}, x_t] + b_j) \tag{4}$$
$$C'_i = tanh(W_C.[h_{i-1}, x_t] + b_C) \tag{5}$$
$$C_i = f_t * C_{i-1} + I_i * C'_i \tag{6}$$

where * is a point-wise multiplication operation, W_j and W_C are weights of LSTM with b_j and b_C are the biases. σ and $tanh$ are two activation function of two layers. Finally, C_i is calculated as the weighted sum of the current cell state and previous cell state.

With this we can calculate the output and hidden state at time step t

$$o_i = \sigma(W_o.[h_{i-1}, x_i] + b_o) \tag{7}$$
$$h_i = o_i * tanh(C_i) \tag{8}$$

Here, W_o and b_o is the weights of the output layer. The sigmoid activation is used on top of the linear output. The output is calculated as the weighted multiplication of cell state and the output. A $tanh$ activation is used on top of that which pushes the valued between -1 and 1. We will treat this output of each time step as a feature vector for our application.

The output of the last layer of the LSTM block is of size d, which is a defined output vector length of the LSTM. This is passed to a classifier layer that outputs the vector of length n. Where n is the number of output class in the classifier application. In this case, the output is 2, which are the probability of normal voice and pathological voice. Fig. 2 shows how to RNN calculates added with a dense layer classify the pathological and voice data.

B. Convolutional Neural Network

Convolution neural network is based on the concept of convolution operation from image processing. But the main difference from classical image processing is that the kernels are not predefined to serve any specific purpose, rather it is learned by back propagation based on a loss function.

The CNN model is consists of an input layer, output layers, and some hidden layers. In this case, the hidden layers are all convolution layers and some helper layers of the convolution which are pooling layer and fully connected layers. In this experiment, we used two layers of convolution in the model. The first is passed to the first layer of the model and the generated output is passed to the next layers of the model and so on until the final fully connected layer.

The convolution block is the central building block of a CNN model. The layer is consists of a learnable kernel of filters whose parameters are adjusted during the training. The kernel has a small receptive field which is extended over the entire image volume by sliding through the row and column dimension. During the forward pass, the kernel is passed through the image to generate an activation map of two dimensions. As a result, the filter learns to activate at the particular scenario of having a specific feature at a particular portion of the image.

The size of the output generated by convolution operation is controlled by 3 parameters- depth of output layer, stride, and padding.

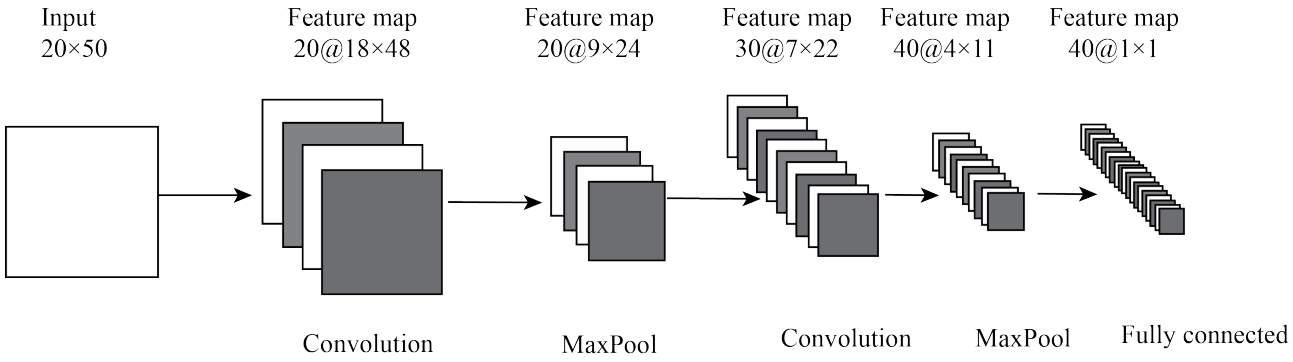

Fig. 3. Passing input data along the convolution layer. The oprations are given in the bottom and the size of the output feature map is shown of the top of the figure

Depth of the output controls the connected neurons in a layer to the same region of the input volume. These neurons combinedly learn to activate at a particular feature. If an input image is passed to this layer, a different combination of edges, shape, and texture of the input image will activate different neurons along the depth dimension.

Stride controls how the kernel slides around the image along the depth dimension. When the stride is 1, the kernel is moved one pixel to the right at a time and after going through all column it goes one pixel down in row dimension. When larger stride size is used the kernel jumps long over the image resulting in an output where the receptive field overlaps and has less correlation. That is why it is very uncommon to use stride size of more than 2.

Padding is used to add extra row and column around the image to let kernel output the first data at the first position of the image by providing the extra data for the kernel to fit outside the image. Sometimes it is important for output size of the image being equal to the input size. In such case, padding is applied.

If convolution operation is applied with a kernel of size K with padding of size P and Stride of S on an input image of size N. The dimension of the generated image will be $(N - K + 2P)/(S + 1)$

The padding size for output dimension to be equal to the input dimension is called zero-padding. Padding size for zero-padding with S=1 is $P = (K - 1)/2$

Pooling layer is another important concept of the CNN Pipeline. It is a nonlinear function used for downsampling the feature map. There are two common types of pooling-max pooling, min pooling, and average pooling. Among them, max pooling is the most common. It divides the data into a small fixed sized non-overlapping subregions. For each subregion, it outputs the maximum of all values in that area. The intuition is the rough apparent location of features of an image is more important than the exact location of features. That is why we can downsample the image with max poling without losing much information but giving a computational advantage for the next layers. It reduces the computational parameter for the next layer and also controls overfitting. Due to the aggressive compression nature pooling is conducted with small kernel size. The most common kernel is 2×2.

Fig. 3 shows the layers of the network and the output feature dimension of that layer. The input is compressed into small feature map by convolution and pooling layer which is the input to a fully connected layer. One final classifier layer is added with a softmax activation to generate the probability distribution of each output class.

IV. Experiment

A. Data

In our experiments, we have used 'Saarbruecken Voice Database' dataset. It's a collection voice recording of more than 2000 persons. Every session of recording includes the recording of the vowels [i, a, u] which was produced at a normal, high and low pitch, vowels [i, a,u] with rising falling pitch.

B. Feature Extraction Using Mel-frequency Cepstrum Coefficients

MFCC is a very common technique for obtaining feature vectors from a sound. MCCs The cepstral presentation is the inverse of the Fourier transform of log magnitude of Fourier transform. SpeechCepstral provides properties of the signal. Each tone of the sound is measured with frequency t in Hz, thus, an inward pitch is obtained on a scale is called Mel Scale. It is the frequency less than 1000Hz and more than 1KHz on the logarithmic scale. are commonly derived as follows:

Signal Strengthening

In this step, we pass a signal through a filter so that it highlights higher frequencies. It increases the energy of signal and leaves the low-frequency components in their original state. This is computed as

$$\phi = e^{(-2\pi F \Delta t)} \tag{9}$$

TABLE I
RESULT ANALYSIS ON ALL EXPERIMENT MODELS.

Model	True Positive	True Negative	False Positive	False Negative	Precision	Recall	Accuracy
GRU	105	123	46	38	73.42	69.53	73.07
LSTM	106	123	46	37	74.12	69.73	73.39
CNN (2-layers)	108	125	44	35	75.52	71.05	74.67
CNN (3-layers)	109	127	42	34	76.22	72.18	75.64

Here t represents the sampling period of our input sound.

Frame Fragmentation

This process involves segmentation of input samples which were converted from analog to digital data into small frames of length 20 to 40ms. Signals are divided into N fragment and adjacent frames are separated by M. Usually, the values of N and M are 100 and 256 respectively.

Windowing

In this step, the Hamming window is used as the next block that integrates the nearest frequency range. This window is used because it resists the signal not to be zero at the edges of window [15].

Lets say the window is Hw(n),0nN-1, where N=sample amount in each frame and equation is defined as follows:

$$y(n) = x(n) * Hw(n) \tag{10}$$

Fourier Transform

In this step we apply Fast Fourier Transform on the three component of equation (2) as x(w), H(w), and y(w) respectively.

$$y(w) = FFT(h(t) * X(t)) - H(w) * X(w) \tag{11}$$

Mel Filter Bank Processing

Since the extent of the output from the previous step is very wide, we apply Mel Filter to scale it. Triangular filters used to compute the weighted sum that is filter generated.

$$F(mel) = [2595 * log10(1 + f)700] \tag{12}$$

Discrete Cosine Transform

This step converts previous step's Mel Spectrum into spatial domain by DCT(discrete cosine transformation). The result is called MFFCs and a particular set of it is called features or attributes, used as the input of our models.

C. Train

We used mfcc to generate a matrix of size (20×50) from the voice data. For the experiment with RNN, we used one LSTM block followed by a classification layer. We chose the hidden size of 128 for LSTM hidden state and used the output of the last layer only as the input to the next layer. The output of the dense layer is 2.

For 2 layer CNN we used two convolution layer followed by two max pooling layer. For 3 layer CNN we have used one more convolution layer. The kernel size of the convolution layer was (2×2) with a ReLU activation function. We used two fully connected layers on top of convolution layer and a Dropout [16] layer in between them to prevent overfitting. The output of the first layer is 128 and the second layer is 2.

D. Result

We trained the model highly compressed data generated from the voice data. We trained four models and a few experimental settings of this. There is two RNN model with GRU and LSTM block, two are CNN with 2 and 3 CNN layers. The best-found accuracy of both models is given table II.

TABLE II
ACCURACIES ON DIFFERENT EXPERIMENTAL MODELS.

Model	Accuracy
GRU	73.07%
LSTM	73.39%
CNN (2-layers)	74.67%
CNN (3-layers)	75.64%

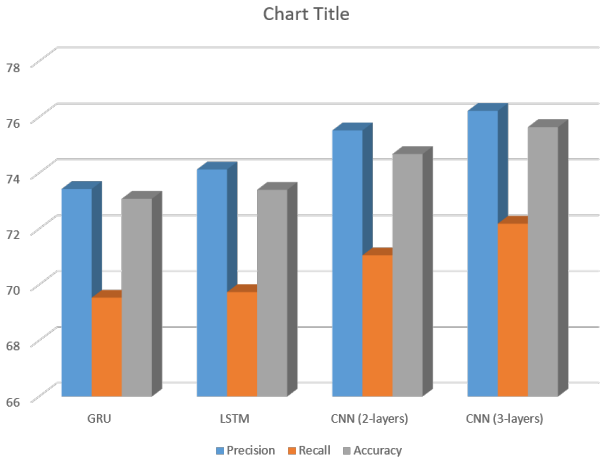

Fig. 4. Precision, Recall and Accuracy of different models used in experiment.

We can see from the data that the CNN gives better accuracy than the LSTM although the LSTM was the first candidate for sequential data. To further analyze the result we have reported the performance in precision and recall. The precision is formulated as $tp/(tp + fp)$ and the recall is calculated as $tp/(tp + fn)$. Table I shows the calculated precision, recall, and accuracy of all models in the experiment.

Fig 4 shows a visual summary.

We conducted multiple experiments of CNN model to find the best parameter for training the model for this task. We also trained on different feature vector size. We got a good result with reasonable training time at vector length 50. Fig. 5 shows the accuracy convergence of different training settings.

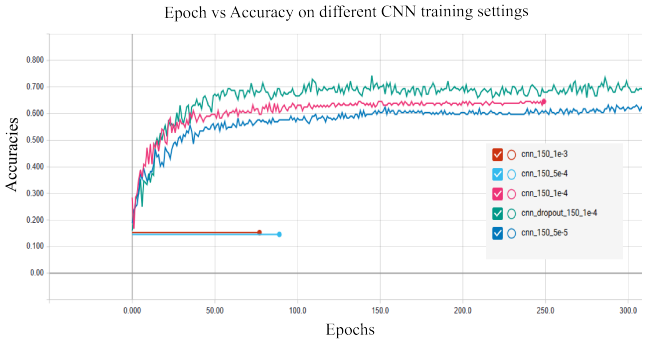

Fig. 5. Accuracy of different CNN model training approach. The first word of the experiment nace is the model name, in one case with extra layer name. The second word is the length of each sequence. The last word is the learning rate.

V. Conclusion

In this work, we build a classifier on voice dataset of pathology detection to illustrate the accuracy of different approach of possible models. Although the recurrent neural network is appropriate for sequence modeling we have shown that CNN can be a possible candidate for such a task and sometimes does better than LSTM if the sequence length gets longer. We have compared the accuracy of those models and also compared different hyperparameter settings to find the best parameters for the future experiment of relevant tasks.

***Abstract*— Lane detection and tracking in highway road is one of the most crucial tasks for advanced driver assistance systems (ADAS). Advanced driver assistance systems are being developed to assist driver in driving process reducing road accidents. In this paper we present efficient lane detection and tracking method in highway roads. To do this, the first step is camera calibration used to remove the effect of lens distortion. Next canny edge detection algorithm finds the edges of the images. Then an adaptive region of interest (ROI) is selected. The ROI is actually based on the triangular shape appeared at the bottom of the image. ROI removes the unwanted region. After that possible lane markings are identified using Hough transformation analysing lane candidate pixels. Once the lane candidate pixels along with the lane are found, these pixels are continuously scanned to obtain the best fit using linear regression analysis. The system has been investigated under various illuminations in highway roads for detecting lane marking. The experiment shows that the proposed method can detect the lane quickly and accurately.**

Keywords — ROI segmentation, lane detection, Hough transformation, advanced driver assistance system

I. Introduction

Advanced driver assistance systems (ADAS) are being developed to assist driver in their driving process reducing road accidents. Car safety and road safety are thereby now-a-days a most important issue. Human errors are prone occurring most of the road accidents in highway roads. Drowsiness of driver is one of the main factors for road accidents. ADAS provides the automated system to automate, enhance and adapt with the environment to reduce road fatalities and avoid the collisions. The system either alerts the driver or take necessary actions of driving tasks [1] providing necessary information like lane departure warning (LDW), position of vehicles, road boundary. One of the scientific field involving in these tasks include computer vision that perform tasks automatically compared with human visual system task. Computer vision senses the environment and can be applied in many applications supported by intelligent vehicle systems (ITS). Autonomous vehicle is a newer arena of computer vision ranging its level from fully autonomous vehicle to vehicles where a driver is supported by a computer vision based systems. Road boundaries, texture and lane markings are the most perceptual cues for human driving. Autonomous systems are also likely to be expected to rely on the perceptual cues that human do. Computer vision is pioneered with artificial intelligence and digital image processing that extract 3D image for images achieving full scene understating. This paper presents an efficient lane tracking system which is capable of providing a real time performance in finding lane markings in highway road based on region of interest along with the triangular shape in various illuminations e.g. day, night and sunny. Finally this detected line is best fitted with curve fitting where the left and right lane boundaries smoothly progress.

The structure of the paper is organized as follows section I provides introductions, section II describes literature review, section III contains the proposed method, section IV presents results and discussions and in section V conclusion is discussed briefly.

II. Literature Review

Various approaches have been discussed for lane detection system. Understanding of lane marking includes detecting the structure of road, the position and number of lanes, splitting, merging and ending lanes and roads in highway road. Much progress has been made possible in recent years. Various sensing modalities like stereo monocular vision, LIDAR, GPS, has been used for better improvement in understanding lanes [2]. A top-view transformation model has been proposed for a vehicle parking assistant [3]. Here perspective projection image is transformed into corresponding bird's eye view followed by a fitting parameters search algorithm. A region of interest (ROI) segmentation technique has been applied for intelligent highway safety [4]. In this algorithm a top-hat transformation is being created as a preprocessing step for enhancing contrast of the image. Then Hough transformation has been used for lane departure decision. A vision based lane departure detection technique has been developed [5] for urban roads. This technique uses Sobel operator. Then straight lanes are detected based on Hough transformation estimating the lane

width. A horizontal line detection technique has been presented for detecting horizontal line under which the lanes are present [6]. This method uses a vertical mean distribution. Then canny edge detector is applied marking edges of lanes and noise candidate. Finally K-means clustering and RANSAC algorithm has been applied for detecting lanes. Edges based lane detection method has been analyzed step by step [7]. Few known and common edge detection algorithms like Sobel, Canny, Roberts and Pewit were analyzed and evaluated using image segmentation, morphology, image statistic and Hough transformation. A layered approach has been provided for lane detection at night [8]. The bottom part as ROI is set here eliminating the sky and other irrelevant objects. In further step the color channel is averaged to obtain gray scale. The dashed lines are elongated using temporal blurring. Then bright objects are extracted by threshold. Low resolution Hough transform is applied on the resulting binary image consisting of left and right halves. Finally a matched filter is iterated to extract lane markers. Three modules-lane model generation, parameter estimation and matching has been developed for lane detection based on geometrical and Gabor filter [9]. Lane gradient maximized image has been created from a color image for lane detection in various illuminations [10].

III. METHODOLOGY

This section illustrates the lane detection and tracking algorithm in highway road in various illuminations. The steps of our proposed method are drawn in "Fig. 1". The system consists of few subsystems: camera calibration, noise removal, Gaussian blurring, canny edge detection, ROI selection, Hough transformation and finally curve fitting.

A. Capturing Image

The first step involves capturing image. The input data is a color image sequence captured by a CCD camera. The camera is mounted just at the front view mirror along the central line of the road inside the vehicle. It captures image from the front view of vehicle including road curvature, trees, buildings, shadows, vehicles and so many objects which do not come under consideration. The real time computer system attached with image capturing card read the images in real time and store them in memory. After that the proposed system read the image sequences stored in memory and then start the further processing steps. Few captured images from highway road during day time, sunny and night depicted in "Fig. 2".

B. Camera Calibration

Camera calibration may be required to calibrate the captured image due to its distortion. Geometric camera calibration also referred to as camera resectioning, measures the parameters of camera lens and image sensor of the captured image. These parameters are used to correct because of lens distortion and measure the object's size in world unit as well as for determining the location of the camera in real application. To estimate camera parameters like intrinsic, extrinsic and distortion coefficients, 3D world coordinate system points and their corresponding 2D image coordinate system are measured. To do this, a checkerboard is a best example as a multiple image of calibration pattern. Calibration

Where W is scale factor, [x y 1] represent image points, [X Y Z 1] is world points and P is camera matrix shown in Eq. (2).

$$P = \begin{bmatrix} R \\ t \end{bmatrix} k \quad (2)$$

The optical centre of the camera points the origin of the camera's coordinate system that comprises the rotation R and translation t. However the intrinsic matrix K is calculated based on its focal length, principal length also known as optical centre and skew coefficient.

C. RGB to Grayscale conversion

Segmentation of lane boundary from the road surface using the color information becomes difficult for edge detection. The gradient of the road surface and lane markings change invariantly due to its shadows, buildings, trees and invariant illumination. Images are made of pixels and each pixel in the image is a combination of three intensities. Therefore images are converted into grayscale meaning that three channel color image consisting of red, green and blue channel-24 bit is now converted to one channel gray 8 bit. The point of using a grayscale image processing is a single channel is faster than processing a three channel color image and less computational intensive. The basic form of the conversion is defined in Eq. (3).

$$Y = 0.299R + 0.587G + 0.114B \quad (3)$$

Y, the gray scale representation of the color image is the weighted sum for the red, blue and green component value. "Fig 3" shows effective result of conversion.

D. Noise Removal

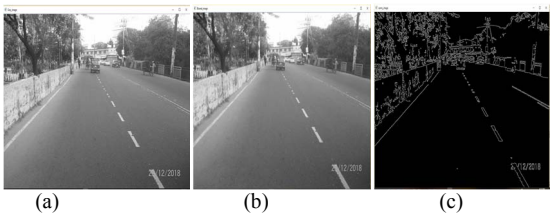
Noise is a real world problem and almost always undesirable in image processing. The goal of image filtering is to enhance the image contrast and to recover the image being degraded. Noise removal is a prerequisite step for edge detection and thus smoothen the image. When detecting edges it is important to accurately catch as many edges in the image as possible. Image noise must be filtered out as it creates false edges and ultimately it affects edge detection. A typical filter-Gaussian filter being used to filtering out noise of image. Grayscale image is represented by a single number that describes the brightness of the pixel. Basically the value of a pixel is modified by average value of the pixel intensities around it. Averaging out the pixels in the image to reduce noise is done by the kernel of normally distributed numbers and finally each pixel value equal to the weighted value average of its neighboring pixel is set. The probability density function of a Gaussian random variable is given by Eq. (4).

$$P(z) = \frac{1}{\sqrt{2\pi\sigma}} e^{-\frac{(z-\bar{z})^2}{2\sigma^2}} \quad (4)$$

E. Edge Detection

Edges are the points where the gray scale values change sharply. Edge detection is a very important step in determining the location of lane boundaries as the edge is one of the major information contributors to the lane. The main factor of edge detection is the detection of the exact edges along with the good orientation of the lane boundary in the image. Because the memory required to store the edges of the image is less compared to the whole image view. However it contains all information of the lane boundary and also orientation of the lane. In our system we applied Canny edge detection, a standard and popular edge detection algorithm. The Canny edge detector works in a multi stage process. The method is based on the characteristics of intensity values of considered pixel. A signal to noise ratio (SNR) on the edge detector may be applied so that edges could be found even the data quality is poor. Gradient is the change in brightness or discontinuity over a series of pixels. So, Canny function computes the gradient in all directions of blurred image and then trace the strongest gradients as a series of white pixels as shown in "Fig. 3". Two arguments low threshold and high threshold allow us to isolate the adjacent pixel that follows the strongest gradient. The basic form of edge detection using canny is defined in Eq. (5) and (6). Edge Gradient,

$$G = \sqrt{Gx^2 + Gy^2} \quad (5)$$



$$\theta = tan^{-1}\, Gy/Gx \quad (6)$$

The threshold value finds the optimum values for the lower and upper threshold in potential data analysis is defined in Eq. (7).

$$T_1 = \min_{\substack{X=0,1,\ldots\ldots,m \\ Y=0,1,\ldots\ldots,n}}\{f(x,y)\} \text{ and } T_2 = \max_{\substack{X=0,1,\ldots\ldots,m \\ Y=0,1,\ldots\ldots,n}}\{f(x,y)\} \quad (7)$$

F. Region of Interest

The region of interest is basically a polygonal selection from 2D image. ROI defines the border of the lanes that comprises individual points of interest. Preprocessing examples of selecting region of interest using matplot are shown in "Fig.4".

(a) (b) (c)

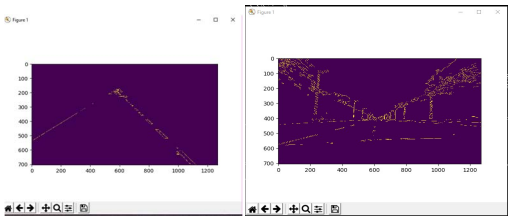


Fig. 3. Processing example of detecting edges a) Gray image b) Blurred image (c) Canny image.

In this step lane lines are detected using ROI that excludes the other irrelevant objects. There might be several objects in the image that are not of interest like trees, buildings, human

etc. A ROI is isolated based on the region of interest that traces a triangle limiting the extent view. Ultimately this triangle isolates the lane lines which are shown in "Fig. 5" and "Fig. 6". The enclosed of the triangle shape is completely filled white as the mask image. Here the canny image is masked with the mask image to trace the ROI triangle shape by bitwise –and operator. Thereby masking the entire region, the operation occurs element wise, so all the white pixels in the region will be operated against the corresponding region of canny image. So, by bitwise and operation which means successfully masked our canny image to ultimately show the ROI the region traced by the polygon contour.

G. Line Finding Using Standard Hough Transform

This step involves using Hough Transform technique to detect straight lines in our region of interest and thus identify the lane lines. This technique uses a parametric space called Hough space. Hough transform is a mechanism that gives more weightage to pixels that are already in line by a voting procedure. This voting procedure is carried out in a parameter space from which lines are obtained as local maxima. The lines that are outside the space are rejected. For example any horizontal line that is not part of the lane boundary can be neglected as well. Hough transform halves the image splitted in yielding left and right side of the image and limits the

search space to 45^0 for each side. Every line has two quantities its slope m and intersect c. With these two numbers, a line can be described completely. Every line in the xy space is equivalent to a single point in mc space shown in "Fig 7". However Hough transform is to convert points in the xy space to line in mc space. For canny image, every point that is nonblack are converted into lines in mc space. Obviously some lines intersect shown in "Fig.8". And these intersections are the parameters (m, c) of the line. Hough transform is a technique that can be used to record vote for each point lies i.e. to look for lines that get many votes. These points of intersections are inside a bin of Hough space for every point of intersection there are to cast of votes inside the bin that it belongs to bin with the maximum number of votes as shown in "Fig. 9". And this is how the line that can be drawn .Polar coordinate system in replace of Cartesian coordinate system using rho and theta is expressed in "Fig.10". Whatever the values of theta, the line is drawn since it was voted as the line of best fit scribing the data based on the threshold. Threshold is the minimum number of intersections to detect a line previously mentioned in a series of points. Hough space represents the theta and rho values of lines that are common between a series of points. For every point of intersection of vote inside the bin it belongs to a line with some value of rho and theta. Finally lines are detected from a series of points in the gradient image using Hough transform and these lines are shown in the original color image by blending the lines with the original image as shown in "Fig 11".

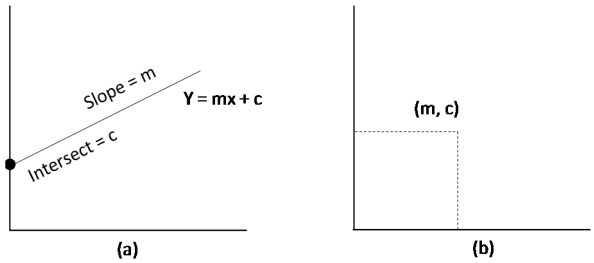

Fig. 7. a) xy space b) mc space

H. Finding Lane Line

Multiple lines with different slope and length are formed using Hough transform. The ultimate solution is to have only two lines, one for right and other for left lane .And it is important that the lines depending on either side are all roughly more or less going to the same direction. Left line has a negative slope and right one has a positive slope. Averaging out the slope and y intercept of multiple lines into a single line traces out both of the right and left lane. Left fit contains the averaged lines on the left and intuitively right fits containing coordinate of the line at right. So both the lines are going to have the same vertical coordinates are going to start at the bottom and go upward. Hough lines vary in length, so the most important and appropriate lines are those which are longest in length. Any detected line traced by less than minimum line length will be rejected. Since shorter lines may be due to the noise or other random calculations.

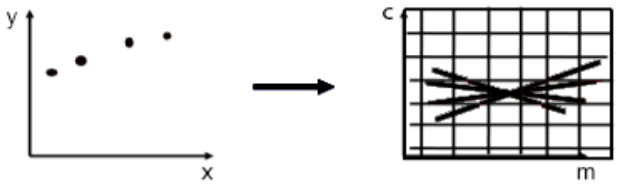

Fig. 8. Finding lines in an image using Hough Transform -each edge point in image space vote for a set of possible parameters in Hough space

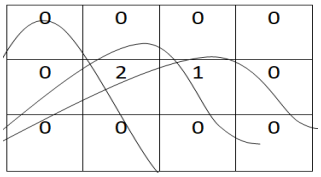

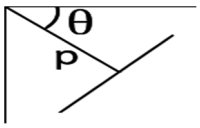

Fig 9. Processing example of Hough Transform voting system obtained as local maxima.

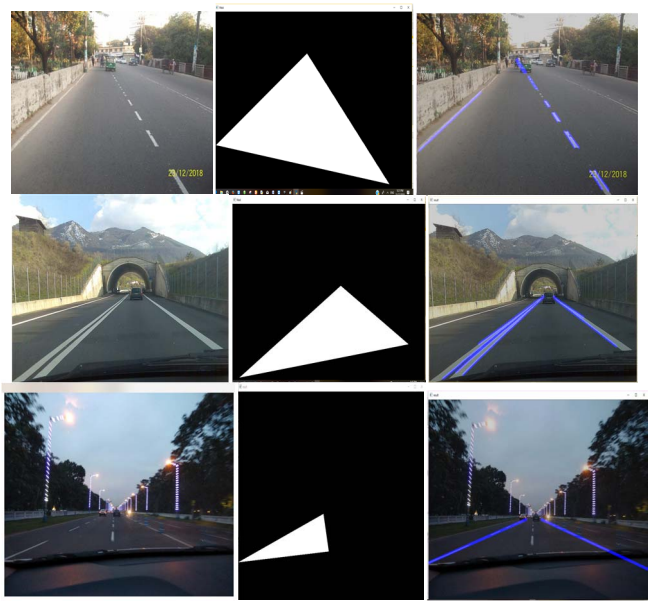
$$p = \cos\theta + \sin\theta$$

Fig. 10. Polar coordinate system



I. Curve Fitting

For curve fitting least square method is used to fit the data points. This phase uses the two vectors of data points from the lane scan as input. For simplifying the data points (x_1, y_1), (x_2, y_2), ... (xn, yn) in lane boundary are observed. The function f(x) = ax + b is the formula commonly used to fit the data. The coefficients a and b in the formula f(x) are the parameters that are adjusted. However, there may be inevitable measurement errors in the observation. The best try is to choose the parameter of the function so to minimize the fitting error-the distance between the data values yi and those given by the fitted curve at the x-values where the data was originally collected ri = yi - f(x) for i = 1,2,.....n. For optimization the least square fitting the parameters of f are chosen to minimize mean square error. “Fig. 12” shows the processing examples of curve fitting for lane tracking straight and dashed lane detection in highway.

IV. Results And Discussions

The experimental results of some lane detection images are explained in this section. All the experiments were executed on the intel(R) Core(TM) i5-4200U CPU@1.60 GHz 2.30 GHz processor with 4 GB RAM. All our proposed systems were implemented using python 3.7 and OpenCV library. The system was built up on recorded RGB images from a digital camera in 2560x1920 resolutions. For processing the resolution were resized in 704x1269 formats.

The experiment is performed on moving vehicles shooting in highway roads under various illuminations with different distances ranging from 10-60 meters. The camera height from the ground should be a certain value that is not more than two meters. The experimental results of lane mark detection and the time complexity of the proposed system is summarized in Table I. As observed from the table the detection rate for the tested image is 98.6 %.The captured images from different distances and the detected resultant images are shown in “Fig. 13”. The blue lines in the images show the result of final processing of lane detection. As observed from the figures that the lanes can be easily detected in different distances and different illuminations with so many noises. The results reveal that the proposed system is not affected by the environment of the streets; have the ROI selected suitable for any set of frames recorded by the camera. However, some problems are not solved yet such as sharp curves in the foreground of the image and the accurate detection of the lanes under the heavy rain. The overall performance of the proposed system is performed qualitatively and quantitatively. This evaluation ranges in highway during day, sunny and night few frames had been shown with detected lane during various illuminations.

d	40	0.43	98
e	60	0.48	97

V. CONCLUSION

In this review, we have presented a frame work which is robust for lane detection and tracking in highway road. This presents a detailed analysis of the use of lane position in various environments with different illuminations. This led to our presentation of the ROI based lane-tracking system operated in a wide range of environments. For safe lane systems, this approach developed a safety system for avoiding lane departure for a large and complex set of traffic scenarios. Besides the application of driver assistance, the Google driverless car can also be included along with lane keeping support system for future work [11]. Google's fleet of robotic Toyota cruises which drives in busy highway roads, city traffic and mountains roads, steering by itself with no driver. According to our experiment result of the proposed method in this paper, we can conclude that this system can be used under most of highway road in daylight, night time, sunny and so on. Also it can be used under various – straight lines as well as with dash lines, lane markings and vehicles for lane boundary recognition. Based on ROI and Hough transform voting system, the system can recognize lane boundary by means of computer vision and forward collision functions. Gray scale statistic, ROI, Hough transform-voting based approaches are applied to recognize the lane boundaries. The system provides high availability, reliability and accuracy. In addition to this, computer vision system supports full installation conveniently. To simplify the installation step, the systems are almost adaptive to most of the vehicles.

Abstract—This project about sign language conversation interpreter system. It is made for speak disable people. Here a man who don't know the sign language can make conversation with a speak disable people. In this project we used efficient methods to convert sign language into text. We used our own dataset and collected dataset of Bangla Sign Languages using hand gestures. Inputs will be taken by webcam and recognized by neural network system. System will show text output by using gestures. We have created a CNN which is similar model of the MNIST classifying model. It can use both Tensorflow and Keras. This model was trained using Keras by video streaming. In a video stream sign language, interpreter can turn it fast into text. We used histogram back projection method to recognize people's hand as object. For better result we calculated the grey level of hands. *Index Terms—Video streaming, CNN model, Keras, Tensorflow, OpenCV, Histogram backprojection.*

I. INTRODUCTION

In this modern era, we have advance technology to utilize human ability more and more. But some people are physically disable by birth or for unexpected accidents. In this world about 15% people are speak disable (according to WHO reports). It's about 8% of the Bangladesh's population. They have to lead their life as burden in society. This burden word is applied because they can't make conversation with Normal people and that's why they can't gain skills of any work. Basically, people who are hear disable and speak disable, they need to learn sign language for communication. At this matter, for communication, sign language is the preferred form. But most of the common people do not understand sign languages. For making communication between the people who use sign language and the people who do not understand sign language, sign language interpreter's service can be arranged. In this way of communication, it is important to know how to make use of the services of the system effectively. Every country has their own sign languages. Our country has also well-formed sign language. Many researchers are working on sign language recognition systems. In our country most researchers worked on Bangla sign language, a system developed by Pavel et al. [1] analyzes video clips of different gestures of sign languages taken as input and gives audio output.

II. GOALS AND OBJECTIVE

We have a huge population who are speaking and hearing impaired. In our development country they a very little chance to make them self-dependent as they can't communicate with others. If they can communicate, they can do all works. They have to face under humiliation situation in every step of life. Now-a day's people mostly depend on technology. We want to speak disable and hearing disable people can lead a modern life through this advanced technology. Our main goal, they can communicate all common people and take parts in all of work of our life. We want to make this people our assets not burden in our society.

III. LITERATURE REVIEW

In 17th century western countries sign language developing was started for a visual language where the conventional gesture, hand signs was, finger spelling also includes the positions to represent a meaningful line. In Europe, Laurent Clerc first taught French sign language. Then Thomas Hopkins Gallaudet brought Clerc to America. His plan was to start American school for deaf. After that from all over the world children came to attend this school and brought their home sign language. Before 19th century whole sign language system was confined only by fixed words using finger spelling system [13]. They probably figured and created signs to understand and speak with deaf people. Khedkkar Safaya and Prof. (Dr.). J.W.Bakal of Mumbai researched on Real time based hand gestures in 2013. They used a dynamic vision censor which can recognize bare hand gesture. They figured out the delivery point track number for every frame and compared with given threshold values. They took this point to detect frame and find the hand position. They calculated the wrist point in the extraction phase used their own algorithm to define the hand sign. In our country our Bengali sign language is formalized in 2003 by CDC (Center for Disability in Development).

Bengali language is the world's 5th language in terms of population. There are 47 alphabets in Bengali language where is 11 vowels called "SOROBORNO" and 36 constants called "BENJONBORNO". But it's true that in conversation people don't use alphabets. That's why sign words should interpreted. Bikash Chandra Karmokar[14] and his team of Technology did a research employing Neural Network Ensemble. They took input from webcam. They also detected skin color of hand. After that captured image had been converted into its threshold value. In 30x33 scale pixels, images were converted by applying normalization process. Then feature extraction method has been applied and they used NCL algorithm to train these images.

IV. METHODOLOGY

Our main target is to capture image by our system and match it with our data set and show the outputs as Bangla language. For this work we take a lot of images of different people's hand sign in different specific gesture. Then we created 15 different gesture samples using OpenCV Library. We convert those captured images into 50x50 pixels and made our dataset. This system works in two steps. At first this system will take dataset images then it applies the skin detection algorithm and detect the skin and remove the background. We used Convolutional Neural Network (CNN) in this system and we created a CNN is looks a lot of similar to classifying model using both Tensorflow and Keras. If anyone want to add more gesture images in this project, they need to make their own layer and some parameters. We trained this model using Keras on videos stream. Which trained by 4 Bangla font, 5 numbers and 6 words. For run this project have to meet with some requirements. The instruments and requirements are given:

1. Install Python 3.x operating system

2. Tensorflow 1.5 using command

3. OpenCV 3.4

4. KerasAPI

5. CPU

For collecting data, Bangla sign language recognition is not still a widely researched topic so we did not find any dataset on any resources. So that, we made our own dataset. We captured images from hundred people bare hands for fifteen different signs and some examples are shown in Fig.1.

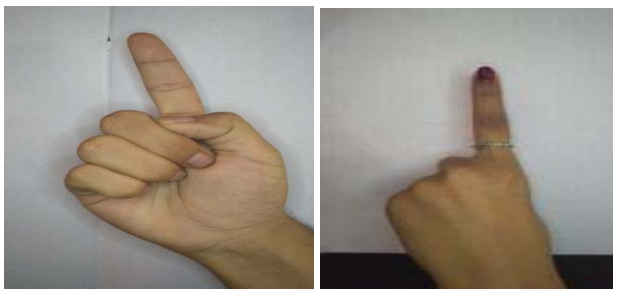

Fig 1: Image Conversion of ১

Fig 2: Data collection (Image Conversion of অ & আ)

But for our collecting image we have to apply skin detection algorithm which detect the skin color pixel from it and identify the blob and remove all binary objects. Then it converts the image to inverted image. So, the hand gestures turned into a black and white image. That is shown in Fig.2.

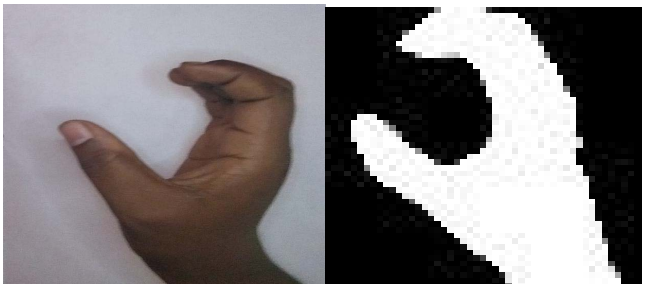

Fig 3: Image Conversion of গ

To create gesture, we used python create_gesture.py command. By using this command, we can create gesture instantly. These gestures can take instance image from us for defining specific signs. As in our country, skin color vary man to man we inputted our dataset in each gesture for better result. All these images are in grayscale which is stored in the gestures. The pictures were flipped by using flip_images.py. The script flips every image along the vertical axis.

For training our dataset we created a CNN model which is similar to MNIST Classifying model. For starting our model, we used some basic code of google tensorflow. We divided our model in three layers. First layer is for recognizing gestures. Second layer helps first layer to show the right output. Third layer is for decreasing processing time. we use two library of CNN model. One is Tensorflow and another is Keras. Keras can run over Tensorflow. So that, anyone can use either Tensorflow or Keras. Keras is a modified model of CNN. In tensorflow there is default command for training dataset. We trained our dataset in every gesture by running cnn_tf.py file. By using these we trained our dataset and we got good result to convert the sings to text which can make a conversation between deaf and numb in Bangla in future.

In this set_hand_hist.py file we write the code to set make histogram in our camera position for 50x50 pixel from where the camera only hand gesture, for making real time gesture to compare with our dataset. This histogram setting is very important in light cases. We need to set hand histogram in every time for light changes. Because it is light sensitive. Which is shown in Fig.4.

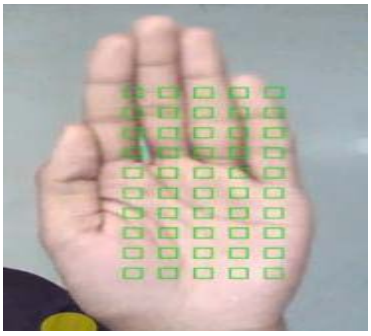

Fig 4: Hand set up

V. RESULTS AND DESCUSSION

In our proposed system to measure the performance we use fifteen types of signs and in future we want to increase the numbers of sign. We use 100 images from 15 datasets. Our first dataset contains 100 images and the average accuracy is 81%.

A. *Experimental Result*

Total class of images =15;
In one class number of images = 100;
Our final dataset contain 1500 images.

For testing our model, we make some gestures in front the camera to test our model. As we read a lot of papers and try some similarities projects, we understood that our model is working as well. Some of the results are given below

Table I: Resulting dataset

ক	
থাম	
১

গ	80%
ঘ	81%

B. *Get model report*

To get classification reports about the model we have test_images and test_levels file which have generated load_image.py. If we do not have them run load_images.py file again. Then we have to run below file.

Python get_model_report.py

We will get the confusion matrix, f scores, precision and recall for the prediction by the model.

Precision: precision is the piece of related instances among the retrieved instances. High precision means that an algorithm returned substantially more relevant results than irrelevant ones.

Table V: Accuracy measure based on performance matrix

Class	Recall %	False positive rate %	Specificity %	Precision %	F-measure %	Accuracy %
আমি	82	11	81	78	87	90

Statically analysis of accuracy, F-measure, Precision, Specificity, false positive is shown in Fig.4.

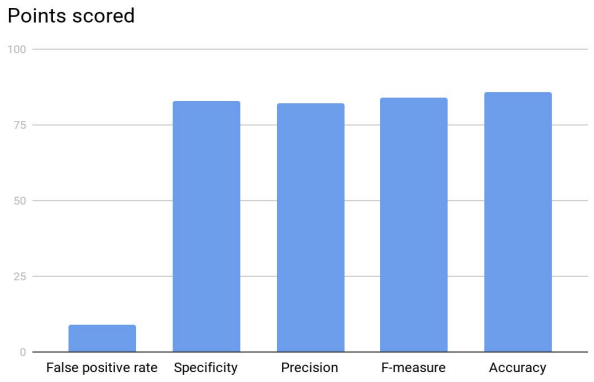

Fig 4: Statically analysis of accuracy, F-measure, Precision, Specificity, false positive

Overall, result is satisfying. Our project can show result over 80%. Our model and gestures are well formed and project can process result in high accuracy and with fast processing time. We need to set hand histogram for every

light change condition. Our project also lightly backgrounds sensitive. Background noise sometimes effect on results.

VI. CONCLUSION AND FUTURE PLAN

In Bangladesh about 4.8 milloin people who are disabled in hearing or speaking. This huge population can be our assest if they can make conversation with us. In this paper, we showed about 15 combined Bengali sign language where has Bengali sign language alphabets, some Bengali sign language Numeric numbers and individual signs too. Our main goal is interconnect thisspeaking and hearing imapired people with common people. Without this interconnection, We can not turn them into skillfull and self-dependent population. In the future, Our goal is to make this system more efficient. We collected our own data-set. That's why It took huge time to collect data and train data. In future our target is to collect and combine all Bengali sign language alphabets , all Bengali sign language numeric numbers and other individual Bengali sign languages. This is modern era. Most of the people in our country use smart phones. We will work to make a phone-based application of this system for making easy communication with all.

***Abstract*—Nowadays, micro-blogging sites like Twitter, Facebook, YouTube, etc., have become much popular for social interactions. People are expressing their depression over social media, which can be analyzed to identify the causes behind their depression. Most of the researches on emotion and depression analysis are based on questionnaires and academic interviews in non-Bengali languages, especially English. These traditional methods are not always suitable for detecting human depression. In this paper, we introduced a Gated Recurrent Neural Network based depression analysis approach on Bangla social media data. We collected Bangla data from Twitter, Facebook and other sources. We selected four hyper-parameters, namely, number of Gated Recurrent Unit (GRU) layers, layer size, batch size and number of epochs, and presented step by step tuning for these Hyper-parameters. The results show the effects of these tuning steps and how the steps can be beneficial in configuring GRU models for gaining high accuracy on a significantly smaller data set. This work will help psychologists and concerned authorities of society detect depression among Bangla speaking social media users. It will also help researchers to implement Natural Language Processing tasks with Deep Learning methods.**

***Index Terms*—Depression, Bangla, Social Media, Gated Recurrent Neural Network, Hyper-parameter Tuning**

I. Introduction

The objective of Artificial Intelligence is to imitate and analyze human behaviors. In this course, detecting human sentiment and emotion is an important part for which Machine and Deep Learning approaches are being widely used. Sentiment and emotion classification can be analyzed further from two different perspectives, specifically, detecting sentiment and emotion from image data, and sentiment and emotion detection from textual data. In both cases, psychological and technical knowledge is essential to analyze the data. In a general sense, sentiment analysis covers the overall area of positive, negative, and neutral sentiment classification tasks. Emotions, such as happiness, sadness, depression, disgust, etc., are rather deep sentiments which are much more difficult to analyze. Some of these emotions are deeper than others which requires high-level psychological knowledge and more sophisticated technical approaches to study.

Depression is one of the deepest human emotions. With a mechanical way of life, more and more people are falling into depression [1]. Depression is a mental disorder which destroys not only the corresponding person but also affects the morality of that person causing him/her to commit unsocial activities, even suicide and murder. According to the World Health Organization (WHO), over 300 million people were suffering from depression in 2017, which indicates an increase of more than 18% between 2005 and 2015 [1].

Most of the research work on depression analysis are survey and one-to-one communication-based. Technical knowledge of depression analysis can help psychologists to detect and analyze depression and causes behind it. Micro-blogging sites like Facebook, Twitter, LinkedIn are now more popular than ever before. On these sites, people frequently share their daily activities and emotional reactions. Wang et al., used Sina, a Chinese micro-blogging website, to collect data and applied psychological knowledge to extract features from it [2]. They demonstrated the use of Naive Bayes, Decision Tree and Rule-based classifiers for their depression detection task.

Bangla is the seventh most spoken language in the world [3]. However, depression analysis in Bangla is still to be done. Riyadh et al., used Naive Bayes classifier with Laplacian Add-1 Smoothing for emotion classification in Bangla [4]. They collected Twitter data from Sentiment140 and used only the core texts for their research work. Their emotion classification covered happiness, sadness, surprise, and disgust. In another research work, Chowdhury et al. performed sentiment analysis in Bangla [5]. They used a hybrid mechanism consisting of both Lexicon based and Machine Learning approaches. They acted upon a semi-supervised bootstrapping approach with Support Vector Machine (SVM) and Maximum Entropy (ME). They collected their training corpus from Twitter.

Neural Network based Deep Learning approaches are becoming more and more popular for semantic analysis, such as emotion classification. Recently, in 2017, Suhara et al., introduced a self-reported history based depression detection procedure using Recurrent Neural Network (RNN) [6]. Hassan et al., used Long Short Term Memory Recurrent Neural Network (LSTM-RNN), a Deep Learning model, for performing sentiment analysis in Bangla [7]. Their work involved both normal and Romanized Bangla.

Can et al., performed multilingual sentiment analysis on limited data using RNN based model [8]. They assembled data from Amazon reviews, Yelp restaurant reviews, and Competition restaurant reviews. Their work covered sentiment analysis in English, Spanish, Turkish, Dutch, and Russian languages. Ayata et al. used both Deep Learning and Machine Learning approach for sentiment analysis [9]. They gathered data from Twitter and trained Support Vector Machine (SVM), Random Forest (RF), Naive Bayes, and LSTM-RNN. Their work concluded with the decision that in most of the cases, Deep Neural Network based approaches perform better than Machine Learning approaches. In their work, only SVM accomplished slightly better performance than LSTM.

In this paper, we introduced the Gated Recurrent Unit (GRU) Neural Network based depression analysis on small Bangla dataset, collected from Twitter, Facebook, and native Bangla speakers using Google form. Labeling human emotion related data requires knowledge of human behaviors. Hence, we hired a Sociology student, who is experienced in dealing with human emotions, to label our dataset. We applied step by step Hyper-parameter tuning while implementing GRU model. Then, we compared each implementation of Hyper-parameter tuning and showed how to tune different Hyper-parameters in an easy way to accomplish better performance on a very small dataset. We have manipulated four different Hyper-parameters, specifically, model size, no. of layers, batch size, and no. of epochs. Apart from applying the GRU model for depression detection from Bangla social media data, our other aim was to focus specifically on GRU model performance over a significantly small dataset. In Bangla, it is reasonably difficult to manage a large dataset due to lack of enough research works. Hence, for Hyper-parameter tuning, we only focused on the aforementioned four Hyper-parameters, without following any specific Hyper-parameter optimization approach.

The rest of this paper is arranged as follows. In Section II, we have discussed some relevant existing research works, our proposed method is described in Section III, and in section IV, the results of our method and relevant discussions are presented. Finally, we conclude our work in Section V along with some future plans.

II. Related Works

In this section, some available research works related to Machine and Deep Learning based sentiment and emotion analyses are described.

A. Machine Learning for Emotion Analysis in Bangla

A Machine Learning based human emotion analysis approach is described by Riyadh et al., in [4]. In this research work, authors selected happiness, sadness, surprise, and disgust for their classification task. They collected tweets from Sentiment140, labeled them manually, eliminated tweets with no emotion, and created a balanced dataset containing 3,750 tweets. 3,500 tweets were selected as their training dataset and 250 tweets as the testing dataset. For feature extraction, Unigram model and Unigram model with POS tagging were used. Authors used the frequency of Bag of Words model as a feature to train their classifier. They used Multinomial Naïve Bayes classifier for the classification task. To avoid zero probability problem of Naïve Bayes classifier, they used Laplacian Add-1 Smoothing by assuming the training dataset to be very large and by adding one to each count. Against 4-way classification, they gained an average of 81% accuracy for Unigram model. For the Unigram model with POS tagging, they gained an average of 79.5% accuracy. For the 5-way classification task, they gained an average of 66% for Uni-gram model. For Uni-gram model with POS tagging, they gained an average of 64.8% accuracy.

B. RNN for Depression Forecasting

A novel method for depression forecasting was established by Suhara et al., using RNN [6]. The authors developed LSTM-RNN based deep learning algorithm. They used their model to produce embedding layers regarding every categorical variable, which also incorporates a day-of-the-week variable to determine the day-of-the-week consequences in their model. They collected depressed data from 2,382 self-declared depressed persons, covering 22 months time span, via a smartphone application. Their model was successfully able to forecast 84.6%, 82.1%, and 80.0% severe depression cases in 1, 3, and 7 days beforehand, respectively. Additionally, the model was successful in detecting overall depression cases with 88.6%, 86.0%, and 84.2% accuracy for forecasting 1, 3, and 7 days beforehand, respectively.

C. Machine Learning for Depression Analysis

Wang et al. conducted an experiment on Sina micro-blog, a Chinese micro-blog, which is one of the most influential social media services in China [2]. They emerged both Psychological and Machine Learning knowledge for their experiment. From Psychological perspective, they used ten features, such as 1st person singular, 1st person plural, positive emoticons, negative emoticons, mentioning, being forwarded, being commented, original blogs, blogs posted between 0:00 - 6:00 o'clock, and one other. From the technical perspective, Machine Learning techniques, such as Decision Tree, Naive Bayes, and Rule-based classifiers were used. Their described method contained mainly three steps, namely, sentence and word segmentation, polarity calculation of sub-sentences, and polarity calculation of sentences. Their model was able to accomplish 80% precision.

D. CNN and RNN for Natural Language Processing

Yin et al. presented a systematic comparison between CNN and RNN in [10]. Their research work covered a wide range of representative NLP tasks, providing basic

guidance for Deep Neural Network (DNN) selection. They systematically compared CNN, LSTM, and GRU models. It covered a broad range of NLP tasks, such as sentiment classification, relation classification, textual entailment, answer selection, question relation match, path query answering, part-of-speech tagging, etc. For their experiment, on each step, they trained their model from scratch, used basic setup without complex tricks, like batch normalization, searched for optimal Hyper-parameters, analyzed the basic architecture and utilization of the models. This experiment concluded that, generally, RNNs perform better and robust for NLP tasks, except for some cases, like keyphrase recognition task.

III. Methodology

Our proposed approach for depression detection from Bangla dataset is divided into two steps - *Creating Bangla Dataset* and *Training GRU Model*. We put special efforts for preparing Bangla dataset and shown steps for Hyperparameter tuning.

A. Creating Bangla Dataset

We used Twitter as our primary data source. We collected 5,000 Bangla data from Twitter and 210 depressed Bangla statements from native Bangla speakers using google form. We prepared our dataset into three steps - *Data Pre-processing*, *Data Labeling*, and *Data Post-processing*.

1) Data Pre-processing: For data pre-processing task, we created a white list containing Bangla alphanumeric characters, punctuations, and space. We scanned each tweet character by character, filtered out all non-white listed characters, and removed multiple consecutive white spaces. An example of twitter data cleaning is given in Fig 2. We only had to pre-process the tweets, as data collected via google form were clean.

Table I: Part of the labeled and stratified dataset

Data no.	Data	Label
34	ওরাল রিহাইড্রেশন সলিউশন ও আর এস প্রস্তুত করার ১২ ঘন্টার মধ্যে বা রেফ্রিজারেটরে রাখলে তা ২৪ ঘন্টার মধ্যে পান করে ফেলা উচিত ।	Non-depressive
33	রাজনাথ সিং সংসদে বললেন এই নাকি ফাইনাল নয় । এই লক্ষ লোক কে আবার নাকি সুযোগ দেওয়া হবে নাগরিত্ব প্রমাণ করার । এটা কি আইওয়াশ নয় ? এরা আর কি প্রমাণ দেবেন ? পাসপোর্ট , আধার ভোটার কার্ড সব ই তো বাতিল করে দিয়েছে । আবার অনেক পুরুষের নাম আছে অথচ তাদের পরিবারের নাম নেই । এরা কি করবে ?	Depressive
118	আহা ! গভীর গহী নের নিঃশব্দ সুর সা থে আঁধা রের ঘ্রাণ !	Non-depressive
117	প্রায় ৪০ লক্ষ বাঙালি দেশ ছাড়া হতে চলেছে সামলাতে পারবে তো পৃথিবী ?	Depressive

2) Data Labeling: Deep human emotions, like depression, are extremely difficult to analyze. In order to make our depression detection dataset more reliable, we hired a Bangla speaking Sociology student, experienced in dealing with human emotions, to manually label our Bangla dataset. A total of 5,000 Bangla tweets were labeled. After labeling, we eliminated incomplete and ambiguous tweets. Our initial tweet set consisted of 984 depressive tweets and 2,930 non-depressive tweets.

3) Data Post-processing: After pre-processing and labeling our dataset, we eliminated redundant data from both tweet set and depressed statement set collected via a google form. After removing redundancy, our dataset was imbalanced with 1,289 non-depressive and only 588 depressive data. An imbalanced dataset may lead to wrong accuracy and over-fitting problems, where accuracy for data within the training dataset would be high, while accuracy for data outside of the training dataset would be low. Hence, we randomly selected only 588 non-depressive data from the labeled dataset to balance with 588 depressive data. In this step, our balanced dataset consisted of only 1,176 data of which 588 were depressive and 588 were non-depressive.

Stratifying Dataset. The balanced dataset was very small to train with a neural network. Therefore, we stratified our dataset to reduce the effect of its small size while training the GRU model. In this step, data were rearranged into a one-to-one approach, that is, one depressive data followed by one non-depressive data, and continuously repeated this process all over the balanced dataset. After stratifying our dataset, we considered this dataset as final and used it to train our GRU model.

Part of an example of labeled and stratified data set is given in Table I. The table shows some Bangla data along with their original labels. The 'Data no.' signifies the positions of the data in the final dataset, and how the final dataset was stratified with one non-depressive data followed by one depressive data.

B. Training GRU Model

For training our Gated Recurrent Neural Network Model, we again divided the training phase into two substeps - *Dataset Splitting*, and *Hyper-parameter Tuning and Training*.

1) Dataset Splitting: Each time before training our model, we split our dataset into 80% training, 10% validation and 10% testing set. Validation dataset was only used to avoid over-fitting. We compared different trained models according to their corresponding testing accuracy.

2) Hyper-parameter Tuning and Training: For implementing our model, we utilized tensorflow implementation described in [11]. To get an accurate result using our small dataset, we fixed learning rate of our model to a very low value of 0.0001. Low learning rate helps the model to avoid over-fitting problem so that our model detects depression accurately from any given data. We tuned 4 GRU model

After pre-processing:
নদীর নীচে দেশের প্রথম রেল সুড়ঙ্গ তৈরি হয়েছে কলকাতায়।এবার মেট্রো রাইলের সৌজন্যে দেশের সবথেকে বড় ভূগর্ভস্থ রেল ইয়ার্ড পেতে চলেছে কলকাতায়।যা তৈরি হচ্ছে কলকাতা বিমানবন্দরের ঠিক পাশেই। : ?

Figure 2: Example of data pre-processing.

Hyper-parameters into three steps - *Tuning for GRU Size*, *Tuning Batch Size with No. of Epochs*, and *Tuning No. of GRU layers with No. of Epochs*. Fig 1 represents the effects of Hyper-parameter tuning in each implementation (impl) in terms of validation accuracies.

a) Tuning for GRU Size: We initially fixed no. of GRU layers to 5, batch size to 10 and, no. of epochs to 5 (total 470 iterations) and tuned GRU size over these parameters. We trained our GRU model with size 64, 128, 256, 512, and 1024. Impacts for tuning GRU size are shown in Fig 1 (impl 1 to 5). Our model gained the highest accuracy for GRU size 512 (impl 4).

b) Tuning Batch Size with No. of Epochs: After tuning GRU size, we fixed its size to 512, no. of layers to 5, and tuned batch size along with no. of epochs. We trained our model with batch size and no. of epochs set to 50 and 5 (90 iters), 50 and 10 (180 iters), 5 and 3 (560 iters), 1 and 2 (1880 iters), 25 and 10 (370 iters), 25 and 5 (185 iters), respectively. As time complexity increases while batch size decreases, we had to decrease no. of epochs corresponding to small batch size. With batch size 5 over 3 epochs, our model accomplished the highest accuracy for tuning batch size with no. of epochs. Effects for tuning batch size with corresponding no. of epochs are shown in Fig 1 (impl 6 to 11). It indicates how accuracy changes with different batch size and no. of epochs.

c) Tuning No. of GRU layers with No. of Epochs: In the final step of Hyper-parameter tuning, we fixed GRU size to 512, batch size to 5, and tuned no. of GRU layers of our model. To reduce memory complexity, we decreased no. of epochs while increasing no. of GRU layers. We trained our model with GRU layers and no. of epochs set to 3 and 3 (560 iters), 10 and 3 (560 iters), and 5 and 10 (1880 iters), respectively. For tuning GRU layers with no. of epochs, our model attained the highest result for 3 layers over 3 epochs. The influences of tuning no. of GRU layers on learning curve are shown in Fig 1 (impl 12 to 14).

IV. Result and Discussion

All the steps of Hyper-parameter tuning along with their corresponding test accuracies are given in Table II. On the first step of Hyper-parameter tuning, we started with a low GRU size of only 64 and gradually increased the size to 1024. Our GRU model achieved 59.1%, 70.0%, 67.3%, 74.5%, and 69.1% accuracy for GRU size 64, 128, 256, 512, and 1024, respectively. According to these results, with

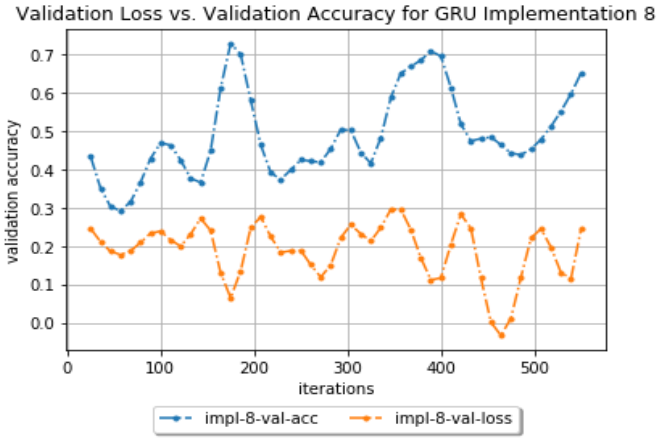

Figure 3: Validation loss vs. validation accuracy for GRU best implementation.

Table II: GRU Hyper-parameter tuning results

GRU implementation no.	GRU size	No. of GRU layers	Batch size	No. of epochs	Test accuracy
1	64	5	10	5	59.1%
2	128	5	10	5	70.0%
3	256	5	10	5	67.3%
4	512	5	10	5	74.5%
5	1024	5	10	5	69.1%
6	512	5	50	5	52.0%
7	512	5	50	10	61.0%
8	512	5	5	3	75.7%
9	512	5	1	2	70.3%
10	512	5	25	10	57.0%
11	512	5	25	5	61.0%
12	512	3	5	3	74.8%
13	512	10	5	3	69.6%
14	512	5	5	10	56.5%

size 512, the accuracy was the highest for this step [impl 4]. These results show that, in most of the cases, accuracy and GRU size acts proportionally.

As on the first step of Hyper-parameter tuning, the highest accuracy was generated for GRU size 512, we fixed this size on the second step, and tuned batch size along with no. of epochs. Our GRU model gained 52.0% accuracy for batch size 50 over 5 epochs, 61.0% accuracy for batch size 50 over 10 epochs, 75.7% accuracy for batch size 5 over 3 epochs, 70.3% accuracy for batch size 1 (that is, online learning) over 2 epochs, 57.0% accuracy for batch size 25 over 10 epochs, and 61.0% accuracy for batch size 25 over 5 epochs. Here, the results signify that accuracy falls for a very large batch size. Also, it is shown that the required no. of epochs is highly dependent on the batch size. However, for fixed batch size, accuracy increases with increasing no. of epochs. Hence, in case of applying GRU, a set of balanced batch size with reasonably large no. of epochs is required for high accuracy. The highest accuracy for this step was 75.7% for batch size 5 over 3 epochs [impl 8]. Accuracy for training with the online learning approach is 70.3% for over 2 epochs.

On the last step of Hyper-parameter tuning, we fixed GRU size to 512, batch size to 5, and tuned no. of GRU layers along with no. of epochs. Our GRU model accomplished 74.8% accuracy with 5 layers over 3 epochs, 69.6% accuracy with 10 layers over 3 epochs, and 56.5% accuracy for 5 layers over 10 epochs. These results led us to the decision that large no. of GRU layers does not necessarily help to perform better on a small dataset. The highest accuracy for this step was 74.8% for 3 layers over 3 epochs [impl 12].

Comparison among all GRU model implementation test accuracies is presented in Fig 4. The validation loss and validation accuracy of the best implementation [impl 8] for Hyper-parameter tuning are shown in Figure 3. The best accuracy we obtained was 75.7% for 5 layered GRU with size 512, batch size 5, and the learning rate 0.0001 over 3 epochs.

This work is the first attempt to utilize a Deep Learning approach for depression analysis in Bangla. Therefore, we are unable to directly compare our results with any relevant works. However, the method described by Suhara et al., is quite similar to ours [6]. They also used a Deep Learning approach for depression analysis. Nonetheless, they were able to create one of the largest depression datasets with 345,158 records over 22 months time span. Hence, they were able to apply LSTM-RNN with their huge dataset. On the contrary, our small dataset contains only 1,176 data, which is crucially insufficient to train LSTM model. This led us to utilize GRU model. Also, their work was to forecast depression in English. On the other hand, instead of forecasting, our model detects depression, which is in Bangla. Embracing all these constraints, our depression detection model still is able to gain maximum 75.7% accuracy, comparing to their LSTM model, which was able to gain maximum 88.6% accuracy. If we were able to create such kind of large dataset, we might be able to accomplish higher performances.

V. Conclusion and Future Works

In this research, we established a GRU model based depression detection technique by analyzing Bangla text data collected from social media (Twitter, Facebook, and Google form). We applied a sequence of Hyper-parameter tuning and showed the corresponding effects of these operations on a small dataset. The results indicate that

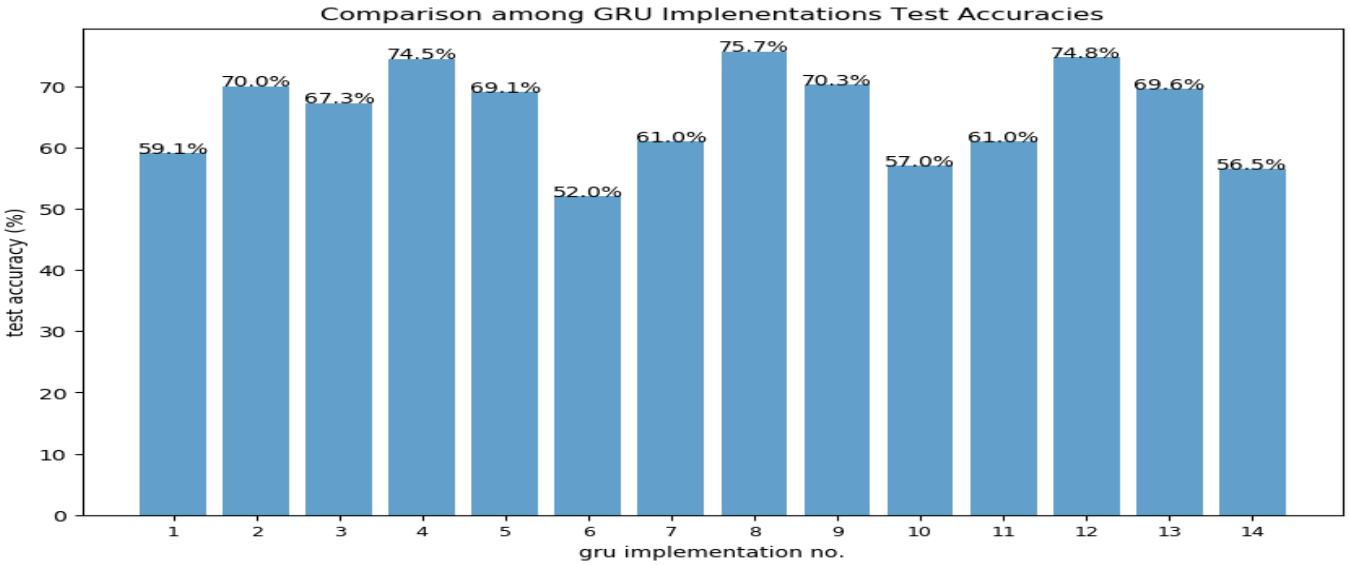

Figure 4: Comparing GRU implementation test accuracies.

in the case of a small dataset, accuracy depends on the variations of batch size and the number of epochs. We have also shown that the required number of epochs is highly dependent on the batch size. However, for fixed batch size, accuracy increases with increasing number of epochs. The results conclude that in case of applying the GRU model on a significantly small dataset, a set of balanced batch size with a reasonably large number of epochs is required to obtain adequate high performance.

This research will guide further investigations to analyze Bangla social media data for detecting depression from both small and large dataset using Deep Learning models. Additionally, multiple experienced persons can be used for labeling the dataset to make it more reliable. Furthermore, we have tuned only four Hyper-parameters without following any specific Hyper-parameter optimization approach. However, such kind of approaches, like Evolutionary optimization, Random search, Gradient-based optimization, and others can be applied for more in-depth analysis.

***Abstract*—Garments industry is one of the biggest industries of Bangladesh and a large portion of our population comprises of garments workers who face several problems starting from health and financial problems, discrimination, safety issues and lack of skill development opportunities – which make them more vulnerable and obstruct them from finding a better tomorrow. A country can't march forward with a large portion of it leaving behind and thus we target to improve their conditions by designing an intervention which propels to achieve the target by maintaining a predictive model which predicts on the data collected from the users. It suggests the users who are garment workers, about the available and better opportunities for workspace in the easiest way.**

Keywords—Human Computer Interaction, Mobile, fog computing

I. INTRODUCTION

RMGs are the finished textile product from clothing factories and the Bangladeshi RMG sector is one of the fastest growing sectors in the Bangladeshi economy, with a growth rate of 55% from 2002 to 2012 [1]. Exports of textiles, clothing, and ready-made garments (RMG) accounted for 77% of Bangladesh's total merchandise exports in 2002. Bangladesh's overall export earnings rose by 5.8% to $36.66 billion in FY17 where Bangladesh's export earnings from the apparel sector registered 8.76% growth, reaching $30.61 billion, thus the apparel sector contributing 83.49%, to the country's total exports of $36.66 billion [2]. This not only indicates how much important the sector is for our economy but also how much people are dependent on this and how large the industry is. By 2013, there were approximately 5000 factories. And 3.6 million people out of a total population of over 150 million are being employed by this industry [3]. This huge population suffer from various problems including health issues, economic crisis, life risk, job uncertainty, lack of socio economic development and many others. In this paper we tried to identify and categorize their problems and proposed an interface based on their basic needs, ease of use and usability of this proposed interface. We also proposed a prediction model that predicts suitable workplaces to the users based on the data from all the users.

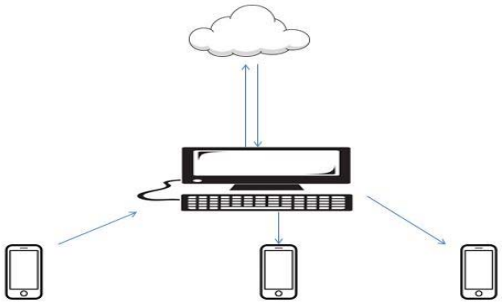

Fig: 1 Automated Model with cloud Architecture

II. RELATED WORK

Finding better and suitable workspace is one of the demanding aspects for almost every employee. So a significant amount of research has been carried out in these fields. Moreover fog computing has been applied to solve numerous problems of HCI too. In order to present our study in more easier and simplistic form we separate our related study into two groups – one is related existing interventions and another is related research works.

A. Related Existing Applications

There are a lot of existing interventions that provide recommendations to the users in diverse fields of interests. But there is none for garment workers for recommending better workplace suitable for them. Criticker is a movie recommendation system which allows users to rank and rate movies and then compare this rating with those of other users and employ "*Taste compatibility Index*" to see how closely it matches with others and then recommend movies that his/her similar testes users prefer [4]. Jinni is another movie recommendation system which uses consumption behavior to create "*unique taste profile*" for each individual or household and also provide user's mood based and effective group based recommendation [5]. There are also a lot of recommendation systems based on user's profile, mood, feedback, ratings and reviews in diverse fields of interests like music, books, games [6] and news [7].There are also a lot of applications for recommending best hotels, restaurants, hospitals etc.

B. Related Research Works

Many researches has been pursued for incorporating IOT with HCI. In 2003, Shou-Hsia Cheng, Ming-Chin Yang and Tung-Liang Chiang uses patient's

ratings of interpersonal and technical performance of the hospital in their study of patient's satisfaction and hospital recommendation system [8].

In 2009, Zei-Mei Wang and Fan Yang utilized GPS information, E-map, comments, tags and ratings for their study of personalized location based restaurant recommendation and navigation services [9].

In 2012, Keunho Choi, Donghee Yoo, Gunwoo Kim and Yongmoo Suh used a hybrid approach of collaborative *filtering* and *sequential pattern analysis* for recommending online shopping malls to the users [10]. In 2015,Kai Zhang, Keqiang Wang, Xiaoling Wang, Cheqing Jin and Aoying Zhou applied collaborative filtering, content based methods, travel intents and diversity techniques in their study of hotel recommendation system based on user preference analysis [11]. In 2015, Binita Gupta proposed a recommendation engine that provides recommendation by collecting information from various real time IOT devices [12]. In 2017, Agostino Forestiero built a distributed recommendation system which uses multi agent algorithm and decentralized and self-organizing strategy [13].

III. PROTOTYPING AND FEATURES SELECTION

Before implementing the interface for the intervention we have done brainstorming, concept mapping, storyboarding and paper prototyping for features selection purposes and we have done two different surveys. One is for validity of our selected features and another is for testing the usability of our designed interface.

A. *Brainstorming and Concept Mapping*

Before starting our work for designing the intervention for garment workers, we first conducts brainstorming for identifying the problems of the garment workers. Then we perform another brainstorming session for selecting important features for the intervention that can provide solutions for those identified problems. After that we groups the number of ideas and thoughts that we have generated in our first and second brainstorming into various concepts.

B. *Storyboarding and Paper Prototyping*

After finishing our concept mapping part, we creates a storyboarding session for our intervention design. This storyboarding helps us to visualize the problems and our proposed solutions for overcoming those problems in a story telling manner. This also helps us to visualize how our solutions will work in real time scenarios. After done with storyboarding we create multiple paper prototypes of our intervention for designing and testing user interfaces. This paper prototyping helps us for easy modification and also eliminates our chance of missing any key features from the design. After finalizing our paper prototype, we designed our application interface in android platform for surveying the usability of our interfaces.

C. *Survey for Features Selection*

We conducted a survey for validating our identified features from the real garments workers. We collected survey results from 30 garments workers. Our survey includes male and female, young and old garment workers. We created 15 key questions to validate our identified problems from the users. We used Likert scale questionnaire for this survey. Likert scale questionnaire is a psychometric scale questionnaire that is used to measure a respondent's attitude or opinion towards a given subject [12]. As most of the garment workers were illiterate, we have to speak the questions to them in Bangla language and collect the response from them. We got highly positive responses for almost all of our questions from the respondents. The results of our survey questionnaires are presented in the following figure.

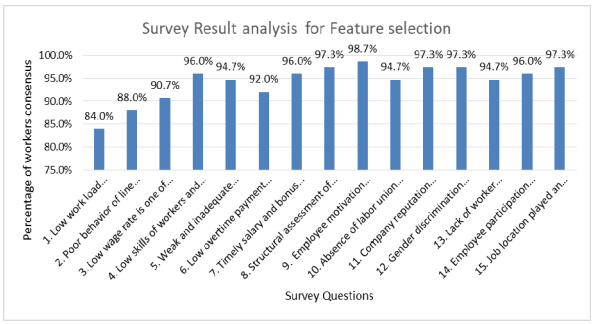

Figure 2: Analysis of survey results in features selection survey

D. *Survey for Usability Testing*

After designing our interfaces we also conducts a usability testing survey on garments workers to test the usability of our application. We used Think Aloud Protocol to conduct this survey [13]. In our survey we test the rollback, interactivity, heuristics, readability, maintainability, intuitiveness, usability, visualization and coherence of our interface. We conducted usability testing survey on 10 garments workers. The following figure shows the results of our usability testing survey.

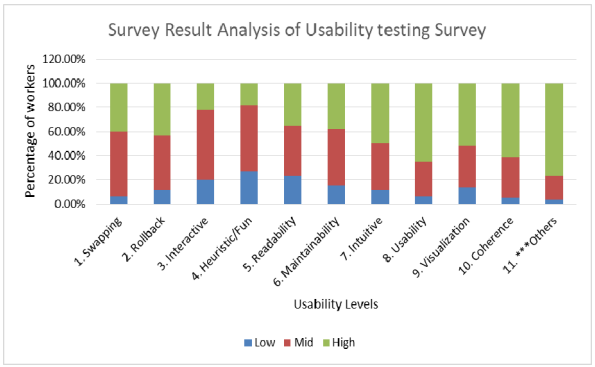

Figure 3: Survey result analysis of usability testing survey

IV. INTERFACE DESIGN

Analyzing user's convenience and usability, we designed the interface in such a way that it becomes at the same time user friendly to the targeted users and efficient in achieving its goal. From our survey we got that most of the users are familiar with form type registration system and thus we created an interface for log in with an extra button named sign up which generates a form when pressed. After filling the form, users get them registered. From our surveys we also saw that 60% users are used to see the main interface after log in and profile in another linked tab. Surveys also showed us that users are also used to find their profile by clicking their picture or any person icon. That's why we placed a person icon in the left corner by clicking

which a user can visit his or her profile. Main interface holds simply a button which finds the most suitable jobs by the predictive model when pressed. In user profile, there is two other tabs one for review where users can find different workplaces by their names and can also review them. In the other tab, there are messages from the system which can also be generated by the users in case of emergency. This software is targeted for workers, most of which are dropouts from primary and that's why we equipped each screen and symbol with Bengali words to make the best use of this app.

V. Data collection

As data plays a significant role in this model thus we propose collection of data from the interface in such a way that it becomes easy for being provided by the users as well as being highly efficient at the same time. While registration, we collect users location which is stored immediately to the nearest fog node of our proposed model. Again if any user decides to review any workplace in the review section, a questionnaire with five questions pops up immediately for each rating criterion of the workplace each is having five different ratings as answers. As we have to rely on these questions and answers for rating these workplaces, we conducted survey for setting which questions are to be placed. All that has to be done by the users is to rate that workplace against these questions which will be saved in the fog nodes. The fog nodes are the ones who hold the predictive model in our proposed system which is fed by these ratings and generates its own rating. Again these ratings are sent to the users and a list of workplaces according to this list and other metrics related to the worker is sent to the users. When any user presses the button named find job in main interface, it simply shows this list. All the data will also be updated periodically to the cloud for making the model better with feedbacks.

VI. Proposed model

We proposed a very simplistic technique to rate the workplaces. Each of the five answers with each of the questions related to the places possesses different values. We propose a rather straightforward approach where each question has ratings as answers to the questions or in other words each place can be rated against each question in scale of 1 to 5. After getting these ratings a very general model inspired from Naïve Bayes model calculates values for these places. When any user rates a workplace, its rating gets updated.

Fog part:

Upon submitting ratings in the review interface, we store them temporarily in user mobiles and in network availability; they are uploaded to fog nodes. Fog nodes initially assign values to all the workplaces. Upon receiving the ratings, it categorizes them by their criterions and respective questions where each question has different weights. For calculating the rating we proposed a novel algorithm as follows,

Algorithm

change_index = **1**
For each $r_i \in$ rating_criterions,R
  For each $q_i \in$ question, Q
    For each $p_i \in$ rating_type, P
      If given_rate equals p_i
        If submitted_rate, p_z exists then
          $p_z = p_z - (1 * change_index)$
          If (number_of_times_chnaged > 2)
          change_index = 1/ number_of_times_changed
          $p_i = p_i + (1 * change_index)$
        else $p_i = p_i + 1$
      Probability $[p_i] = p_i / \sum_{i=0}^{n} p_i$
    For all $p_i \in$ Probablity,P
      rating $[q_i]$ = max $p_i \in P$
  For each $q_i \in$ question, Q
    weighted$[q_i] = w_i *$ rating $[q_i] / \sum_{i=0}^{n} w_i *$ rating $[q_i]$
For each $r_i \in$ rating_criterions,R
  Probability $[r_i]$ = max weighted$[q_i]$ **For All** $q_i \in$ question, Q

All the weights are between 0 and 1. Whichever place gets the higher score moves forward in the list. All the ties are being broken arbitrarily. All the calculations are to be performed in fog nodes. These nodes, after performing these calculations, send the lists to the users which are being shown to them whenever they try to find a job. This list also gets some modifications with the distance metric. Ties in jobs scores are broken by their distance to the individual' s location searching suitable job where nearest jobs gets priority over jobs with equal score.

There is another interface named Messages. This has been proposed with the view of sending emergency messages to the nearest ones in times. If any garments worker writes in the box in the lower part of that tab, that message is being sent immediately to the fog node which can be sent to other users nearby the sender. Fog finds the suitable receivers and forwards them that message.

Alongside performing calculation, fog nodes can send periodic updates to the cloud where cloud can cross match the ratings and cloud can send updates to the list prepared by fog nodes.

Cloud part:

Cloud is periodically updated with the data from the fog node. When number of emergency messages from a certain place exceeds a certain threshold level, it decreases the rating and same occurrence of this event increases the rate of decrease in the rating. This rating is transferred to the fog node and eventually sent to the edge devices (user mobiles) without any modification.

VII. Experiment & performance evaluation

In our experimental setup, we set up a slum of garments workers to run our application in small scale. We setup a local host which acted as a fog node and installed our application in approximately in 50 workers mobiles and set

up a Wi-Fi under which the local host operated. From that, we tracked down the trend of number of users.

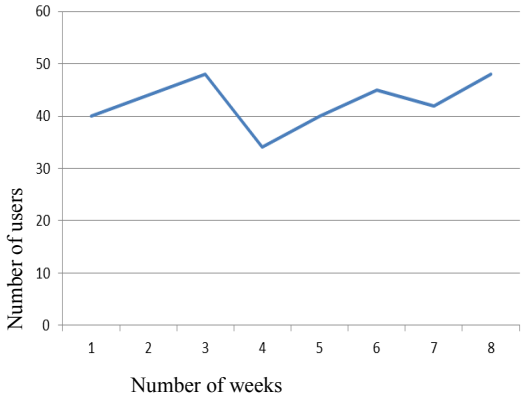

Figure 4: Survey result of number of users

The very first breakdown in the number of users accounts for their initial struggle with the interface. After making them more familiar with the interface, the second breakdown occurs for their concern about the security of their data as it contains highly sensitive information. Though making them understand that it's only for test purpose cleared this, the concern is real and it is a drawback of our system that it doesn't provide any strong measure of security which is needed to be addressed too. We also conducted a survey on 1.Usability, 2. Ease of use, 3. Features and 4.Prospects and the responses above good are projected in a manner below

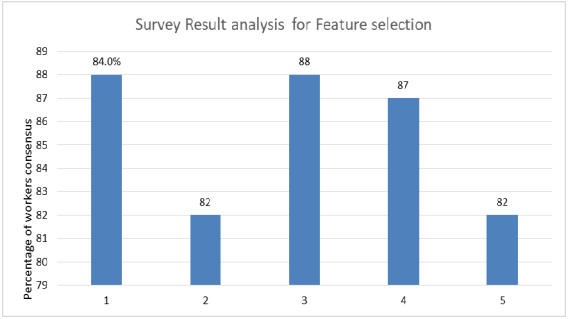

Figure 5: Survey result analysis of usability survey

VIII. FUTURE WORKS

This proposed model can be implemented for various rating prediction including other occupations and educational sectors as well. We proposed this model in job prediction context, but this proposed model can be of good work disaster based systems which we currently working on. Moreover the prediction model is too naïve which surely possess a great scope to improve. If a better model, trained effectively with a good set of training data can be formed it can predict more accurate result which is also our next motive. Moreover, this proposed rating shows suitable workplace based on everyone's ranking whereas suitability can vary from person to person. So suggesting suitable workplace to the user with the help of specific rating provided by that user is also our next motive.

IX. CONCLUSION

Though a lot of recommendation system has been proposed before, our approach in this topic is unique of its kind. The issue of security and implementation of proper neural network is somewhat neglected as this is only a conceptual model but needed to be addressed for a practical approach. Moreover proper analysis of this data can surely help to achieve the targeted goal.

***Abstract*—Eye disease has become serious concern to people, specially who have been suffering from diabetes . Systematic eye diseases are manifest in around the retina of an eye. Digital photography of the retinal images provide a significant information about the disease. This kind of retinal images work as a powerful source for the doctors and ophthalmologist to take meaningful decision about the disease. This kind of Computer Aided Diagnosis(CAD) allow both the doctors and patient to take a second layer of satisfaction. Considering this issues, this paper segmented the retinal vessel images using the state-of-the-art Deep Neural Network(DNN) such as a combination of U-Net and Generative Adversarial Network (GAN) model. As the retinal images suffers due to the Contrast and Illumination problems, this paper also proposed two preprocessing algorithms to reduce this effect.**

***Index Terms*—Accuracy, Augmentation, CLAHE, GAN, Segmentation, U-Net**

I. Introduction

A complicated problem of an eye is Diabetic retinopathy that can affect eyes badly. The back of the eye blood vessels can be damaged by the light-sensitive tissue for this type of complication. Statistics show that this complications affect up to 80 percent [24] of those who is suffering from diabetes for 20 years or more. About 40 to 45 percent [26] Americans having diabetes who have faced diabetic retinopathy at some stages of their life but half of them are aware of it. It occurs when an enormous blood vessels leak blood and other part of the eyes. This causes the retinal tissue to distend, resulting in cloudy or distinct vision. A short areas of balloon-like lump in the retinas enormous blood vessels, called microaneurysms, happen at this first stage of the disease which is called mild nonproliferative retinopathy. When the new blood vessels distract with the normal flow of fluid out of the eye, then eye ball may build up by the pressure. This can harm the nerve that bearing images from eye to brain (optic nerve), turn into glaucoma. Fresh blood vessels may turn in the front part of eye and interfere with the normal eye it can pressurize the eye to increase (glaucoma). Gradually, glaucoma, diabetic retinopathy or both diseases can lead to complete the vision loss.

The risk of blindness can be reduced by early detection and treatment. People with this disease may need eye treatment more frequently. The number of eye specialist and ophthalmologist are not enough for the people who are suffering from these diabetic retinopathy diseases. That is why Computer Aided Diagnosis (CAD) system is needed for the people [22]. The investigation of Retinal images by the researches has a long history. In 1851 first ophthalmoscope was invented by Hermann Von Hemholtz and then in 1926 a fundus camera was invented which could take a 20 degree view of the retina. Therefor, a latest Scanning laser ophthalmoscopy (SLO) technology using laser light to create high resolution images in 1926 [18] . The first technique to detect and segment unusal structures was published in 1984 [27], when Baudoin et al. described a method on image analysis to find out microaneurysms, a characteristic loss of diabetic retinopathy. In 1910, Gullstrand improved the functionalities of the fundus camera, still this concept is used today [19]. Retinal imaging has improved quickly during the last few years and is now a main part of the clinical care and management of patients with retinal type diseases . In 2009 Retinopathy Online Challenge, it was difficult to compare the performance of retinal image analysis algorithms [19]. From this challenge there is a lot of methods and idea came for the future. There are so many proposals to solve those problem. One of the proposal which is consists of (1) optic disc detection, (2) optic disc segmentation and elimination, and (3) blood vessels detection and segmentation and the methods are i) Transformation of Color Channel into Grey Scale. ii) Morphological Operation that is based on Non-uniform Background Removal. iii) Stationary Wavelet Transform for visualization of tiny Low contrast Vessels. iv) Contrast Limited Adaptive Histogram Equalisation (CLAHE) for vessel enhancement [1] .

Different people and research groups are engaged for retinal image analysis and try to improve the effectiveness of the corresponding CAD system. In [2], blood vessels are segmented on retinal fundus images. In here, Gabor filter and morphological top-hat transformation are applied after pre-processing step in order to enhance blood vessels. For accurate understanding the diseases of retinal vessels therafter digonosis of those disease a novel unsupervised mechanism is proposed in [5]. Here author proposed vessels segmentation technique using unsupervised iteretive mechanism. In 2016 a paper is published to increase the performance of segmentation of retinal vessels images [6].

With the time, different advanced techniques and methods are introduced for the natural image classification. Among them the state-of-the-art DNN has gained enormous attention after the famous work proposed by Alex Krizhevesky, in his

model AlexNet in 2012. After that, a lot of variant of this model have been introduced for the image analysis and pattern recognition purposes. Initially this kind of mechanism is introduced for the natural image classification [7] [25]. However, with fine and advanced level of tuning, this models of DNN have been introduced for different objective defined image analysis problems, such as retinal image fundus segmentation. U-Net and Generative Adversarial Network (GAN) models can be considered as one of the variant of Alexnet. In U-Net model, an encoder and decoder are used, and this kind of model are mainly utilized for image segmentation. Where as a GAN model consists a generator and discriminator which is mainly introduced introduced for synthetic data generation. Recently, this kind of techniques are also utilized for retinal image analysis. Inspired by the above advancement of recent DNN, we have introduced a variant of DNN model in this paper which is combined of U-Net and GAN model for the retinal fundus segmentation.

In this paper section I provides introductory features about the objective of this research with some state-of-the-art literature in this area. Section II provide overall classification model and section III provides a structure description about the pre-processing work of this experiment. Section IV describes our proposed model along with schematic description about U-Net and GAN model.Finally in section V discusses our finding and describes the results. In the conclusion chapter, this paper concluded our work with the future direction of further research.

II. Classification Model

Main target of this work for finding out retinal vessel from the color retinal images, this work utilized the following steps to perform the overall segmentation operation as

1) Image Pre-Processing.
2) In classification model both U-Net(which is supervised in nature) and GAN(which is unsupervised in nature) have been combinely used.
3) Performance Evaluation.

Fig. 1: Classification Model

Figure 1 shows the overall classification model.

III. Pre-Processing Steps

Pre-processing is necessary to improve the visibility of macro structure of an image. Different pre-processing steps are necessary based on the image nature and their acquisition techniques. Among different image pre-processing steps, luminance being a major concerned to the researcher as it represents the apparent brightness of an image. Another issue is contrast, which represent a significance difference between two or more things which is unclear when we compare them. It is considered that retinal images are suffers due to low luminosity and contrast issues. Considering this two issues this work emphasis to improve luminicity and contrast enhancement. As Green channel of a retinal image contains more significant information, this work mainly emphasized on Green channel for pre-processing work. In this paper we have used following two algorithms to enhance the contrast and illuminance for retinal images

1) Algorithm-1: In Algorithm-1, image I has been taken which is RGB in nature. To reduce the intensity variation an average filter has been utilized with 2×2 kernel, then we have performed the following steps sequentially such as:

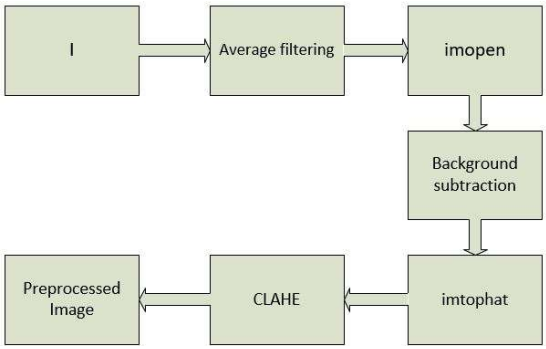

Fig. 2: Algorithm-1

- Morphological Opening: Performing erosion followed by a dilation operation is known as Morphological Opening, it can be represented as $I_{open} = (I \Theta s) \oplus d$
  - The erosion of a binary image I by a structuring elements with kernel size $e \times e$ (denoted $I \Theta s$) produces a new binary image g = $(I \Theta s)$. In the erosion method the targeted pixel $I(x, y)$ is considered to be 1 (or 0), if all the pixel of image I covered by the kernel is 1 (or 0).
  - The dilation of an image I by a structuring element d produces a new binary image g = $I \oplus d$ with ones if one pixel covered by the kernel is 1. Dilation has the opposite effect to erosion.
- Calculate the back-ground image.
- Subtraction of the image from the back-ground.
- Morphological Closing: Performing dilation followed by a erosion operation is known as Morphological Closing $(I \oplus d) \Theta s$.
- Finally we use CLAHE to enhance the contrast. Where the tiles number are 20 by 20 and clip limit is .00005.

2) Algorithm-2: Algorithm-2 performs the preprocessing operation in the LAB space instead of RGB space where the L lightness component and A and B represent the color component. Algorithm-2 is summarized as
   - Converts the image from RGB to LAB space.

- CLAHE operation is performed to improve contrast with NumTiles 8 by 8 and ClipLimit is 0.0001.
- Finally converts the LAB to RGB.

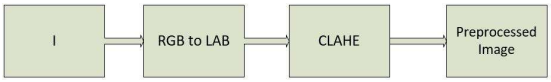

Fig. 3: Algorithm 2

Fig. 4: Pre-processed images

Fig 4 a shows the original image where b and c represents the pre-processed image utilizing Algorithm-1 and Algorithm-2

IV. Our Proposed Model

A. Network Structure

In this experiment, we have utilized a DNN which is the combination of U-Net, GAN, Data augmentation technique .We have described the procedure as follow :

1) Generative Adversarial Network (GAN): GAN [15] is a recent advancement of Deep Neural Network, which is normally used for unsupervised machine learning. It consists of two neural networks one is generator and the other is discriminator.

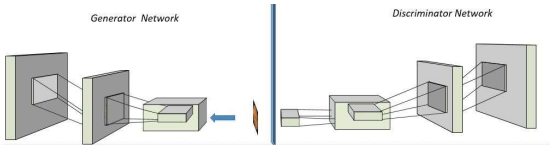

Fig. 5: Generative Adversarial Network Architecture

The generator tries to make new data following a particular probability distribution and passes this the data through the discriminator. The generator makes the data in such a way that it looks like a real data though those are fake or artificial. The target of the generator is to generate images that look like the real images. When the generate data pass through the discriminator the target of the discriminator to recognize those information that are not real. The objective function can be found as follows:

1) Objective Function:: The generator model is written as, $\mathscr{G}(z \rightarrow y; \mathbf{w_g})$, where a given noises distribution z is transformed to an image y. Normally for an image generation, the distribution is considered as Bernoulli distribution. The discriminator is represented as $\mathscr{D}(x \rightarrow p; \mathbf{w_d})$, here x represents the provided trained image and p represents its corresponding probability distribution which lies in the range from 0 to 1. Here $\mathbf{w_g}$ and $\mathbf{w_d}$ represent the weight for generator and discriminator. Discriminator normally works in a two-fold manner such as:

- Firstly it maximizes its weight such that input image x is classified as real data. That means, the objective is maximizing $\mathscr{D}(x)$ [8]
- Secondly, the discriminator tries to reduce the probability of miss-classification of any fake image to a real image. That means the objective is minimizing $\mathscr{D}(\mathscr{G}(z))$

Considering the above issues, the over all loss function [22], [23] $\mathcal{L}$ for GAN can be written as

$$\mathcal{L} = \min_{\mathscr{G}} \max_{\mathscr{D}} \{\mathbb{E}_{x \sim p_{data}}[\log(\mathscr{D})] + \mathbb{E}_{z \sim p_z}[\log(1 - \mathscr{D}(\mathscr{G}))]\}$$

In this experiment, the generator takes a fundus image and generates retinal segmented vessel as the same size of the input [12]. Then the discriminator classify the image weather the image is real (taken from the training set) or fake (created by the generator). The discriminator creates labels for each ingredient in the batch. The loss function are calculated risen from the labels. The images are directly pass through the discriminator because the fake image created by the generator is the part of the same computational graph. In the generator we use U-Net model for segment the vessel image [10].

2) U-Net: U-Net utilize encoder decoder concept for semantic segmentation of an image where encoder utilize downsample concept and decoder utilize up sample concept in a down sampling process few convolution blocks followed by maxpooling operation as given in Figure 5 .

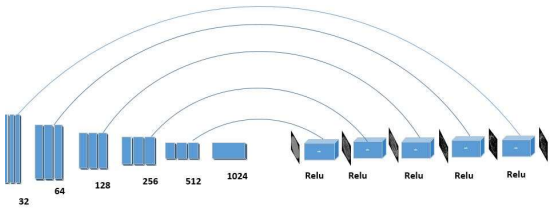

Fig. 6: U-Net model structure

U-Net model has two parts one is encoder and the other is decoder. In this experiment the first layer of the encoder take input image with size ($640 \times 640 \times 1$) and produce output of size ($320 \times 320 \times 64$) which is work as input of the next two parallel layer [9]. The two parallel

layers produce two outputs one is (160×160 × 64) and (80×80×128). Here first parallel output goes to the third layer as input. The 2nd parallel layer concat with the 4th layer and the concat output goes to the 5th layer. In the downsampling there use relu as activation function .

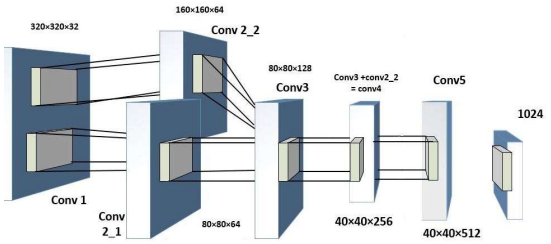

Fig. 7: GAN model generator downsample

After decoding the encoder the segmented image comes by using transpose convolution operation. In encoding process the original information come to in a compressed from. In here as a result of compression the original image loss his information. To increase the resolution with high localization properly an encoder model is concatated after the decoder part. The decoder part continuously decompressed the compressed information utilizing successive layers mention that in this particular procedure the pooling operation is replaced by upsampling operation.

B. Augmentation

This experiment utilizes public database DRIVE as this database contains very small amount of images this experiment created few synthetic images utilizing augmentation method such as :

- left right filp [11]
- 0 to 360 degree rotation with 3 degree incrementation
- z score

C. DATA set description

DRIVE [Digital Retinal Images for Vessel Extraction] [16] database was published for relative studies on segmentation on blood vessel in retinal images. This database is free for educational and research purposes. The images that set for DRIVE database were come through a diabetic retinopathy screening program in the Netherlands. In this program there were 400 people age between 25 to 29 for collecting images. From these images randomly 40 images were selected for the DRIVE database. These 40 images were divided into two group one is training and other is testing where both groups contained 20 images. For the training images a single manual segmentation and for the test two manual segmentations are available. In the case of test images one manual is gold standard and the other is the computer based segmentation. All of the images in the DRIVE database is used for making clinical diagnoses.

D. Package dependency

This experiment utilize a computer with with following configuration

- Processor Intel(R) Core(TM)i5-6200 CPU 2.3 GHz
- Memory 8 GB
- 64-bit operating system in this experiment training lasts for 35 hours.As a software platform here use Tensorflow

E. Result

There are some benchmark criteria to evaluate supervise machine learning technique. The Area Under Curve for Receiver Operating Characteristic (ROC AUC), [13] [28] Area Under Curve for Precision and Recall Curve (PR AUC) and dice coefficient and F1 measure are evaluated in this experiment.

- Receiver Operating Characteristic Curve ROC curve is a graphical visualization that represent the diagnostic ability of a binary classifier system. ROC is a probability curve and AUC is the amount of separability. AUC represent the model that how much it is suitable for distinguishing between classes. Depending on various threshold values a AUC-ROC curve is created to measure the performance of a classification problem. Sensitivity and Specificity are inversely proportional if sensitivity is increased, the specificity decreases. When the threshold decreases, more positive values produce for this reason the sensitivity increases and the specificity decrease.
  Every point on the curve represents a sensitivity/specificity pair. The area under the ROC curve (AUC) is a measurement of how the parameter can distinguish between sensitivity and specificity. In this experiment we utilize two algorithms where Algorithm-1 obtain 90.26 % ROC value and Algorithm-2 obtain 89.91 % ROC value. The sensitivity for the both algorithms 0.630343% and 0.632588% respectively. The specificity for the both first and second algorithms 0.965861% and 0.959156% respectively.

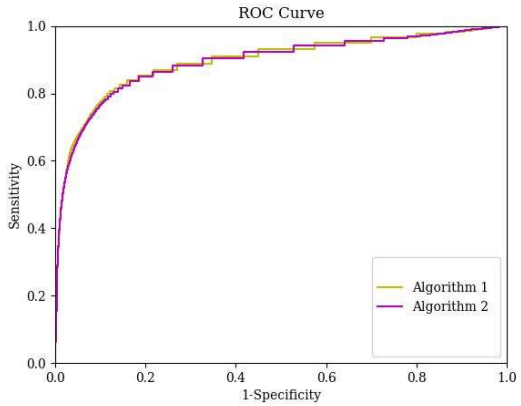

Fig. 8: Receiver Operating Characteristic Curve

- Precision-Recall Curve
  The precision-recall curve represent the balance between two desirable but incompatible features. Recall is the

measurement of the performance of the positive part of the information. Precision is the measurement of the performance of positive prediction. In the precision and recall calculation sensitivity is identical with recall and the positive prediction value is identical with precision. The precision-recall curve show that the performance of the model on different data of the image that is use in the experiment. In the experiment for Algorithm-1 PR value is 0.714784% and for Algorithm-2 the PR value is 0.701368%.

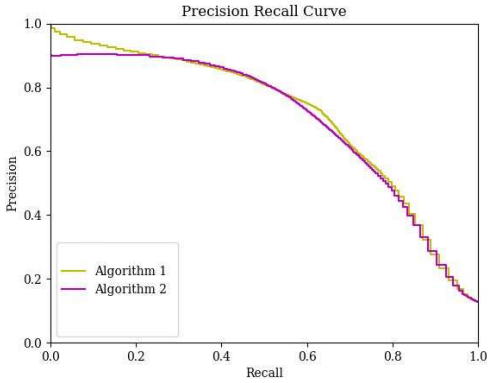

Fig. 9: Pecision-Recall Curve

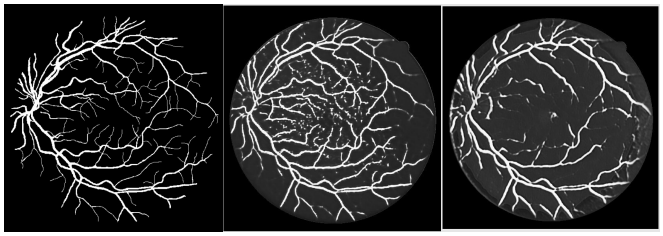

- Dice Score
  Dice score is mostly used to quantify the execution of image segmentation process. In the images there are ground truth region and from the images the dice algorithm calculate the dice score. This is the measurement of the similarity of the images. So, dice score is the size of overlapped of two segmented images. In the DRIVE data there are mask with ground truth.The dice algorithm generate mask/image which is binary that creates a mask for the segmentation . 67.61% and 66.14% dice score value for Algorithm-1 and Algorithm-2 respectively.
- F1 Score
  F1 is a function of precision and recall. F1 score brings the balance between precision and recall. In the case of accuracy the true negative takes for calculation but the F1 score takes the false negative and false positive both for calculation thus the F1 score may be better to bring balance between precision and recall. In the experiment Algorithm-1 has 64.50% F1 score and Algorithm-2 has 66.15% F1 score.
- Accuracy
  Accuracy is one parameter for evaluating classification models. Accuracy is the parameter for predicting that how much the model got right.

The following table summaries all of our findings

TABLE I: Result Summaries

Result	Algorithm 1	Algorithm 2
PR	0.7147	0.7013
ROC	0.9026	0.8991
Dice coefficient	0.6761	0.6614
Accuracy	0.9231	0.9175
Sensitivity	0.6303	0.6325
Specificity	0.9658	0.9591
F1 score	0.6450	0.6615

In Fig 10 a represents original segmented image, b and c represent segmented image for Algorithm-1 and Algorithm-2

(a) Original (b) Algorithm-1 (c) Algorithm-2

Fig. 10: Segmented Images

There are few works have been done on this dataset. M. Li et al. performed Multi-Scale Convolutional Neural Network and obtained 91.7% [29] accuracy. H.Fu et al. perform CNN and Conditional Random Field method and obtained 91 to 94% [30] accuracy. These two results and nearly comparable with our findings.

V. Conclusion

Retinal Fundus image identification is always being an active area of research. With the time being new methods have been introduced and adapted for the retinal image identification and classification. This paper has classified and segmented the fundus image using state-of-the-art DNN, specifically utilized both the supervised U-Net model and an unsupervised GAN model together for the retinal image segmentation. One of the main contribution of this paper is, in the decoder of the U-Net model, a parallel layer has been utilized. The overall achieved result of this model is moderated, however with the fine tuning and adjustment of the parameters, the overall performance can be improved.

Abstract— **Electroencephalogram (EEG) that measures the electrical activity of the brain has been used extensively to recognize emotion. Normally feature based emotion recognition requires a strong effort to design the perfect feature or feature set related to the classification of emotion. To curtail the manual human effort we designed a model by using a virtual image from EEG with Convolutional Neural Network (CNN). Initially, we calculated Pearson's correlation coefficients form different sub-bands of EEG to formulate a virtual image. Later, this virtual image was fed into a CNN architecture to classify emotion. We made two distinct protocols; between these, protocol-1 was to classify positive and negative emotion and protocol-2 was to classify four distinct emotions. An overall maximum accuracy of 81.51% on valence and 79.42% on arousal was obtained by using internationally authorized DEAP dataset. Our proposed method is helpful in recognizing emotions efficiently.**

Keywords—EEG, Convolutional Neural Network, emotion, correlation, virtual image.

I. INTRODUCTION

Simply, emotion means the instant mental state and interaction. The degree of pleasure, displeasure, excitation, sadness, etc. can easily be extracted from emotion. However, emotion is not so simple always because it varies with respect to personality, motivation, mood, temperament, event and with the different environment of surroundings. In spite of having these type of wide variety and complexity, emotion has such unavoidable importance that attracts the researcher significantly from the last two decades.

Now a day's digital technology changes the environment very rapidly. But the improvement of different human interacted media depends largely with the appropriate recognition of the human feeling that means what he or she wants just right at that moment. To communicate computer with human, to detect present feelings of the patient, to understand customer interest for shopping, to realize interest of physically handicapped people or to detect the lie of a convict; emotion recognition is a fundamental prerequisite. Due to these inevitable importance's, emotion recognition has great importance in the field of neuroscience, computer science, cognitive science, and physiology.

Multitudinous approaches have been applied to extract emotion like facial expressions [1], gesture and speech signals, EEG signals, autonomous nervous signals, etc. For facial expression and speech signals, subjects need to express emotion explicitly. On the other hand, subjects have no way to control the automatically generated EEG signal. Therefore, EEG is the best and inimitable signal for emotion recognition.

Recently, deep learning has become an indispensable part in the field of artificial intelligence to process signals and information. Numerous deep learning architecture like Deep Belief Network (DBN), Convolutional Neural Network (CNN), Deep auto-encoder, Generative Adversarial Network (GAN) achieve outstanding result compared to shallow models like SVM, MLP, k-NN, CRF in many challenging fields like pattern recognition and image processing. In modern time for analyzing physiological signal (i.e. EEG, EOG, ECG, EMG) various deep learning-based architectures are applied successfully and attained comparable result [2].

In this paper, we used CNN to classify emotion. Firstly, we decomposed the EEG signal into 5 sub-bands namely delta ($1 \text{ Hz} < f < 4 \text{ Hz}$), theta ($4 \text{ Hz} < f < 8 \text{ Hz}$), alpha ($8 \text{ Hz} < f < 12 \text{ Hz}$), beta ($12 \text{ Hz} < f < 30 \text{ Hz}$) and gamma ($30 \text{ Hz} < f < 60 \text{ Hz}$). Since alpha, beta and gamma subbands are more relevant with emotion [3], we considered only these three sub-bands to formulate virtual image by calculating Person's Correlation Coefficients (PCC). Then the virtual images were set as the input of CNN based classification method.

The plan of the remaining paper is just like that. The background research is described in section II. Section III illustrates the methodology. The CNN model is explained in section IV. The result is reported in section V. At last, section VI terminates the paper.

II. RELEVANT RESEARCH

There have multiple proposed approaches in the field of emotion classification. Primarily the approaches can be classified into two types a) feature-based approaches, ii) deep architecture-based approaches. The feature-based approaches consist of the feature in the time domain, frequency domain, joint time-frequency domain, etc. The Hjorth index [4], simple statistics, non-stationary index, etc. are calculated for the time domain.

In the frequency domain, the popular methods are Power Spectral Density (PSD), Short Time Fourier Transform (STFT) [5], etc. The joint time-frequency domain consists of wavelet-based features [6].

Moreover, with these existing methods of emotion recognition, some scholars have started to use deep learning architecture. Martinez et al. used the skin conductance and blood volume pulse signal with an effective convolutional neural network to classify four emotional states [7]. Li et al. worked using differential entropy with DBN and compared with five baselines improvement of 11.5% and 24.4% [8].

Here, we used the CNN model upon a virtual image formed by Pearson's correlation coefficients and achieved the highest accuracy described in the result section.

III. METHODOLOGY

A. Database description

We made our experiment using DEAP dataset [3]. This dataset of emotion recognition consists of two parts, one is the ratings from an online self-assessment and other is the participant ratings, physiological recording and face video of experiments. The summary of the dataset is given in Table I.

TABLE I: THE SUMMARY OF DEAP DATASET

No. of participants	32 (16 female)
No. of video	40 (1 min long)
No. of distinct emotion	15
Rating scale	Valence, arousal, dominance, liking, familiarity
Rating value	1-9, except familiarity (1-5)
Recorded signals	32- channel 512 Hz EEG; physiological signals; Face video (no. 22)
EEG acquisition medium	Biosemi ActiveTwo

For collecting EEG data, they used the international 10/20 electrode positioning system shown in Fig. 1.

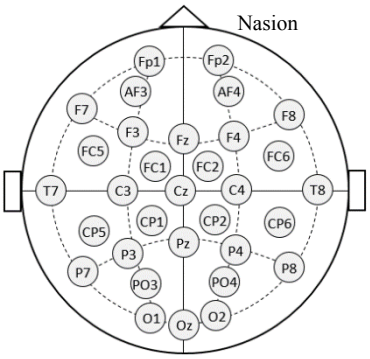

Fig. 1: International 10/20 electrode placement system [3] showing only these 32 electrodes used by 'DEAP'.

The name of 32 channels or electrode associated with 'DEAP' are Fp1, F3, FC1, AF3, F7, FC5, T7, C3, CP1, CP5, O1, Oz, O2, P7, P3, Pz, PO3, PO4, P4, P8, CP6, CP2, C4, T8, F4, F8, AF4, Fp2, FC6, FC2, Cz and Fz. The available data is 3d in the format like video×channel×data = 40×40×8064.

B. Overall experiment

The following block diagram of Fig. 2. represents the overall proposed method.

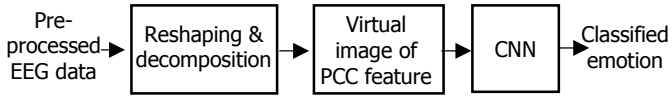

Fig. 2: The simplified block diagram of proposed method.

a) Pre-processing: The recorded raw EEG data of 512 Hz were down-sampled firstly at 128 Hz. Later to remove undesirable upper frequency a (4-45) Hz bandpass filter was applied. The EOG artifact also removed. The preprocessed data were downloaded from the DEAP website.

b) Reshaping and decomposition: Among the overall 40 channels data, we took only 32 channels of EEG data. Then we removed the first three-second pre-trial baseline data. Then the output EEG signal is decomposed into five frequency sub-bands.

c) Formation of a virtual image: EEG is a one-dimensional non-stationary signal. Nevertheless, for classification by using Convolutional Neural Network architecture we need two-dimensional image type data. Here we calculated the PCC between every pair of 32 EEG channels. Since delta and theta sub-bands are related to deep sleep and subconscious mind, we considered the rest three sub-bands for calculating PCC. Thus, we formulated a 32×32×3 shaped three-dimensional data equivalent to a color image, which was termed as a virtual image. Then this image was taken as an input of the CNN model.

C. Pearson's Correlation Coefficient (PCC)

For emotion recognition, many scholars used numerous features like Power Spectral Density (PSD), Differential Entropy (DE), Differential Asymmetry (DASM), Rational Asymmetry (RASM), Wavelet Energy (WE), Relative Wavelet Energy (RWE), etc. We used Pearson's Correlation Coefficient (PCC) of a similar and consecutive point to build a matrix of cross-correlation.

Pearson's Correlation Coefficient or bivariate correlation is a measure of linear correlation between two one-dimensional variables. Mathematically, it is the ratio of covariance of two arrays to the product of their standard deviation. Its value ranges from -1 to +1. Where, +1 indicates 100% positive correlation, 0 indicates no correlation, -1 means 100% correlation but anti or negative correlation.

Suppose that, two different one-dimensional variables are x and y, where $x=(x_1, x_2, ..., x_n)$ and $y=(y_1, y_2, ..., y_n)$. Then the correlation between these two data sequences will be

$$\rho_{xy} = \frac{\mathrm{cov}(x, y)}{\sigma_x \sigma_y} \tag{1}$$

Where, ρ_{xy} and $cov(x,y)$ represents the PCC and covariance respectively between x and y, σ indicates the standard deviation. However, In details, the equation can be written as follows.

$$\rho_{xy} = \frac{n\sum_{i=1}^{n}(x_i y_i) - \sum_{i=1}^{n} x_i \sum_{i=1}^{n} y_i}{\sqrt{n\sum_{i=1}^{n} x_i^2 - \left(\sum_{i=1}^{n} x_i\right)^2}\sqrt{n\sum_{i=1}^{n} y_i^2 - \left(\sum_{i=1}^{n} x_i\right)^2}} \tag{2}$$

D. Experiment Protocol

For a subject, for a single trial video and for a single channel there remain 8064 (63s ×128Hz) data points. As CNN required a large amount of dataset for training, to operate successfully we segmented the data to increase the quantity of virtual image. For doing this after removing the data of first 3 seconds we took only the last 60s data and segmented it into 20 samples each contains 384 data points of 3 seconds. Thus for only one participant, we got 800 samples. Thus we had 25,600 samples of the virtual image in total for all subject. In our work, we have made 2 different protocol.

a) Protocol-1: Here, we just classified two discrete emotions positive and negative. For each participant, we considered the valence and arousal rating. From the rating

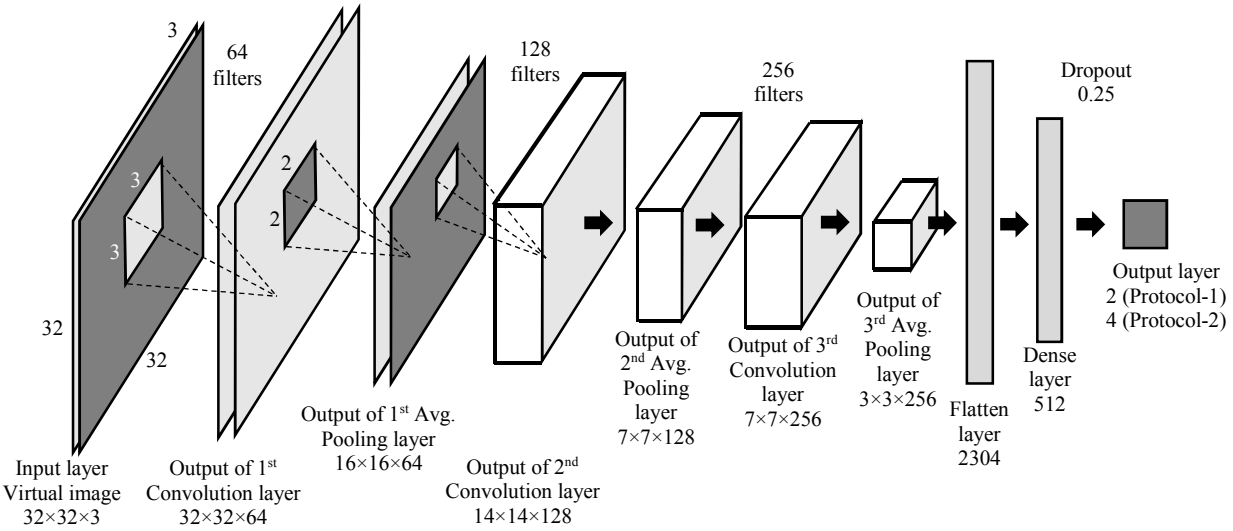

Fig. 3: Proposed CNN model

our model predicts 1 to less than 5 as low and from 5 to 9 as high. We classified as low as negative and high as a positive emotion.

b) Protocol-2: In this section, we classified 4 discrete emotion namely happy, angry, sad and relaxed by using a low and high value of valance and arousal. Here the high and low scaling is the same as the previous protocol. But here we considered low valence low arousal as sad, low valence high arousal as angry, high valence low arousal as relaxed and high valence high arousal as a happy emotional class using Russell's circumplex model.

IV. Convolutional Neural Network Model

Convolutional Neural Network or simply ConvNet is an effective model, which is able to assign proper importance (weights and biases) depending on numerous aspects of the input image and be able to differentiate one from other. A simple CNN architecture consists of a set of a convolutional layer, ReLu layer, and pooling layer. A complete CNN also contains Fully Connected (FC) layer like flatten and dense layer. Our overall model from the virtual image to classified emotion is shown in Fig. 3.

A. Convolution Layer

This layer is the core building block of CNN architecture, which make convolution operation between the input image and the applied filter. We used 64, 128 and 256 filters of size 3×3 and of stride 1 in the 1st, 2nd, and 3rd convolutional layer respectively. The output of CNN layer was then passed through an activation function. Simply, according to pure mathematics, the convolution operation in between two signals *h(t)* and *k(t)* can be expressed as follows.

$$(h * k)(t) = \int_{-\infty}^{\infty} h(t-\tau)k(\tau)d\tau \tag{3}$$

Here, for any single layer of convolution if the size of the input image is $n_H^{[l-1]} \times n_W^{[l-1]} \times n_C^{[l-1]}$ and the size of the filter is $f_H^{[l]} \times f_W^{[l]} \times n_C^{[l-1]}$ then the dimension of the output image after completing a single CNN layer will be $n_H^{[l]} \times n_W^{[l]} \times n_C^{[l]}$ where,

$$n_H = \frac{n_H^{[l-1]} + 2p^{[l]} - f^{[l]}}{S^{[l]}} + 1 \tag{4}$$

The calculation of n_W is similar to n_H. Where $p^{[l]}$ indicates the dimension of padding and $S^{[l]}$ indicates the value of stride at level *l*.

B. ReLu layer

The activation function decides if the neuron would fire or not. There remains different activation function like Sigmoid, hyperbolic tangent (thah), Rectified Linear Unit (ReLu), Maxout, Exponential Linear Unit (ELU), softmax, softsign, Scaled Exponential Linear Unit (SELU) and softplus. Here we used ReLu as activation function which is the best fit with CNN architecture and faster.

$$F(x)=\max(0, x)$$

Lastly we used 'softmax' activation function to classify emotion.

C. Pooling layer

We used average pooling in spite of using normally used max pooling. This is because PCC based virtual image is a texture type image, not like an ordinary image. Here we used a 2×2 matrix with stride 1 for pooling.

TABLE II: The Summary of Applied CNN Model

Layer (type)	Output Shape	Parameter
batch_normalization_v1	32, 32, 3	12
conv2d (Conv2D)	32, 32, 64	1792
max_pooling2d(MaxPooling2D)	16, 16, 64	0
atch_normalization_v1_1	16, 16, 64	256
conv2d_1 (Conv2D)	14, 14, 128	73856
max_pooling2d_1(MaxPooling2D)	7, 7, 128	0
batch_normalization_v1_2	7, 7, 128	512
conv2d_2 (Conv2D)	7, 7, 256	295168
max_pooling2d_2 (MaxPooling2D	3, 3, 256	0
flatten (Flatten)	2304	0
dense (Dense)	512	1180160
activation (Activation)	512	0
dropout (Dropout)	512	0
dense_1 (Dense)	4	2052
activation_1 (Activation)	4	0

After using three sets of convolutions, ReLu, and pooling layers, we used two fully connected layers. The summary of our CNN architecture is given in Table II.

D. Optimizer and Loss function

In machine learning, the commonly implemented optimizers are Adamax, Nadam, Stochastic Gradient Descent (SGD), RMSprop, Adagrad, Adadelta, Adam. 'Adam' can be thought of as a combination of 'RMSprop' and 'SGD' with momentum. It has adaptive learning rates, which can compute the individual rate of learning for a different parameter. Hence, we used 'Adam' optimizer in our experiment. Cross entropy was applied as the loss function in this network.

The training and testing data were split as 80% and 20% respectively. The training epoch and batch size were 50 and 20. We chose the initial learning rate of 0.001 and dropout 0.25. The no of the total parameter is 1,553,808 and the trainable parameter is 1,553,418.

V. Results & Discussions

In our work, one of the main objectives was to convert the one-dimensional signal into a significant 2-dimension signal. By making a virtual image of PCC, we ensured that it is possible to use CNN to classify distinct cognitive state from the EEG signal. The complete experiment was done by maintaining two different protocol. The model output result is shown in Table III in terms of accuracy.

TABLE III: The classification accuracy of our model

Protocol	No. of emotion	Accuracy (Mean ± Std.)	
		Valence	Arousal
Protocol-1	2	81.51±10.7	79.42±11.8
Protocol-2	4	71.67±11.1	70.18±13.5

Hence, it can be notified that our CNN model outperforms in protocol-1 and reached in the state-of-the-art performance to classify positive and negative emotion.

Actually, the proper comparison in this type of research is not so meaningful due to a wide variety of input data, no. of EEG channel, no. of emotion classified. However, a comparison is presented in Table IV.

TABLE IV: The Comparison of result with accuracy

Method		No. of emotion	Accuracy (%)	
			Valance	Arousal
Bahari et al. 2013		3	58.05	64.56
Zhuang et al. 2014 [9]		4	70.90	67.10
Jirayucharoensak et al. 2014 [10]		9	49.52	46.03
Tripathi et al. 2017 [11]		2	81.41	73.36
Our Method	Protocol-1	2	81.51	79.42
	Protocol-2	4	71.67	70.18

The classification accuracy is largely dependent on the no. of output class. The more the no. of emotion have to be classified the less the classification accuracy would be found. However, in this work, our contribution is to propose a CNN based method to recognize emotion from multichannel EEG data, which reduce the trouble of human to manually extract the significant feature.

VI. Conclusions

In this research work, a Convolutional Neural Network was implemented on a virtual image data to classify emotion. The EEG data was firstly reshaped and decomposed and then PCC was calculated to build a featured virtual image. Our achievement was good, but further improvement will be possible by taking a large set of data for training the model. But undoubtedly, our experiment provides the important information that Convolutional Neural Network with significant input data is a very effective and potential network in the research domain associated with human brain signal.

***Abstract*—Educational Data Mining (EDM) is an emerging research field concerned with the application of data mining, machine learning, and statistics in the discipline of education. Many researchers have already focused on EDM and exploring the educational data using several traditional data mining techniques to improve the educational performance of the students by extracting the concealed patterns and predicting the final outcome. In this study, we aim to propose a Deep Neural Network (DNN) based model to predict the final CGPA of the undergraduate business students with a minimal error than the traditional approaches. We have considered the performance of a decision tree model as the baseline performance. Experiments in this study have shown that our proposed DNN model can predict the CGPA with a significantly minimal error rate. To measure the performance of our model we have considered the three evaluation metrics namely Mean Squared Error (=0.008), Mean Absolute Error (=0.067), and Mean Absolute Percentage Error (=2.074). Our proposed model has successfully shown a promising prediction performance by reducing the MSE, MAE, and MAPE by 0.0146, 0.0431, and 6.043 respectively, compared to the baseline model.**

***Index Terms*—Deep Neural Networks, Regression, Educational Data Mining, CGPA Prediction.**

I. Introduction

In the modern era, education is the most important factor to change the world and thus many researchers have emphasized on exploring the educational data and trying to improve the quality of the education, performance of the students, and trying to build up an ideal educational system [1]. Moreover, the educational institutions that are providing higher education have already taken this as a challenge.

As an educational system generates large-scale data within a short period of time, the researchers have focused on the data mining techniques to analyze the educational data. Basically, data mining is an information extraction activity that identifies the concealed patterns in the data [2]. Nowadays, each institution aims at producing higher and exemplary education rates by employing various data mining methods.

The increasing emphasis of the researchers on data mining and education system has already made a new research field named Educational Data Mining (EDM). EDM is an emerging discipline concerned with developing methods for exploring educational data and using those methods to better understand students [3]. Various data mining techniques are engaged in EDM such as decision tree, k-nearest neighbors, association rule, neural networks, genetic algorithms, exploratory factor analysis, and stepwise regression.

In most of the Asian countries, many vicissitudes are observable in the performance of the students during their undergraduate period. Thus, it creates a big problem for both the teachers and students to track the educational performance and take necessary steps to avoid the educational failures. So, an early prediction of the final CGPA can solve the problem and help the teachers, course-advisors, and instructors to identify the students at risk and also give high confidence to students in their studies.

In this study, we have proposed a Deep Neural Network (DNN) model to predict the the final CGPA of the undergraduate business students with a minimal error rate based on the transcripts data of first four semesters. We have considered the performance of a decision tree model as the baseline performance. Our experimental results have shown that the proposed DNN model can predict the final CGPA with Mean Squared Error (=0.008), Mean Absolute Error (=0.067), and Mean Absolute Percentage Error (=2.074). However, the comparison between the proposed model and the baseline model have concluded that our proposed DNN model has successfully performed a promising prediction by reducing the MSE, MAE, and MAPE by 0.0146, 0.0431, and 6.043 respectively.

II. Related Work

Over the past few decades, several studies have been conducted in the discipline of education. In the recent years, most of the research in this discipline have emphasized the use of data mining techniques. Some authors have applied several types of machine learning methods to perform different types of studies including predicting the performance of the students, selecting the optimized features for prediction, and discovering the hidden pattern in the educational data. In this phase, we are going to briefly discuss some of the latest and relevant studies.

To predict students' final GPA using only the grades of the previous courses the authors Al-Barrak et al. [4] have applied decision tree. They have also identified some impactful relations between the courses and final GPA. On the

other hand, Sumitha et al. [5] have proposed a framework to analyze and classify students' detail based on academic records. In their proposed framework, they have applied K-mean Clustering algorithm on the most appropriate attributes selected by the ranking analysis. They have also applied five efficient classification algorithms namely Naive Bayes, Multilayer perceptron, SMO, J48, REP tree to predict the students' performance and J48 outperforms the others with the highest accuracy (=97%).

Selecting the optimized features significantly improve the learning performance of the model. Mueen et al. [6] have identified the appropriate attributes by applying the ranking algorithm and also used 10-fold cross-validation to train up the model. They have tested three classifiers namely Naive Bayes, Multilayer Perceptron, and C4.5 (J48) on 38 attributes to predict and analyze students' academic performance and Naive Bayes have yielded the best accuracy (=86%).

An empirical study on attribute selection has been conducted where the authors proposed a small feature set by using both filter and wrapper methods [7]. The proposed feature set contains 'internal grades', 'previous failure', 'internet usage hours', 'health condition', 'attendance percentage', and 'family relation quality' those are sufficient to make accurate predictions of student grades.

The prominent researchers Daud et al. [8] have applied the learning analytics (discriminative and generative classification models) to predict whether a student will be able to complete his degree or not. They have used information gain and gain ratio to select the best features. For predicting the performance of students they have used five classifiers, two generative models namely Bayes Network (BN) & Naive Bayes (NB) and three discriminative models namely SVM, C4.5, and CART. And, the SVM has been found as the most effective with F1-score 0.867.

As the aforecited paper [5], an identical study [9] have been conducted where the authors proposed an integrated system framework which mentioned six variable domains (psychological, cognitive, economical, personality, demographic and institutional domains) that have a great influence on student performance. Their architectural framework has contained three layers such as the user interface layer, the database system layer, and the execution system layer.

A comparative analysis has been performed between two neural network models, namely Multilayer Perceptron and Generalized Regression Neural Network, to identify the best model for predicting the students' academic performance based only on their academic result [10]. The authors have split the whole dataset into three segments (60:20:20) where 60% have been used as the training data, 20% as the validation data, and 20% as the testing data. They have used three performance metrics: Mean Square Error (MSE), Receiver Operating Characteristic (ROC), and accuracy to evaluate the performance. According to the comparison of these two models the GRNN, with spread parameter 0.45, has been found as the better model than MP with higher accuracy (=95%).

III. Problem Background

In most of the Asian countries, there exists no linear relationship among the performances of a student during the undergraduate period. Some students perform better in the commencing period but worse at the ending period, some perform worse in the commencing period but better at the ending period. Again, there exists a few students who always perform better or worse. Thus, it makes difficulties for teachers, course-advisers or instructors to identify the students who are at risk and to guide them properly.

The prediction of the final CGPA, indisputably, can help teachers, course-advisers or instructors to identify the students at risk and guide them properly. Another significant problem is that at the middle point of the graduation period some of the students become frustrated by thinking that if they eventually not be able to obtain their expected outcome and this frustration obviously influence their performance that increases the possibility of falling out. So, the early prediction of the final CGPA undoubtedly can help the teachers or instructors to take a proper decision for the improvement of students' performance and also carry away the frustration that reinforces their mind to perform better.

Though students' transcript data are available to every educational institutions, it is definitely a challenging task to predict the final CGPA of the students because of the rapid vicissitudes and nonlinierities in their educational performance. To handle the aforementioned problems we have aimed to predict the final CGPA using a DNN approach only by utilizing the students' transcript data of the first four semesters.

IV. Description of Dataset

In this research, we have prepared a real dataset by using the students' transcript data of business students collected from the Marketing department of a renowned university, situated in Bangladesh. The dataset consists of the students' data who already completed their graduation in 2013, 2014, 2015, and 2016. The collected raw data, that have contained 398 instances in total, have been manually processed and organized in a google spreadsheet. The dataset contains the attributes regarding each of the students are Student name, Student ID, Gender, All the courses including course' grade, Semester GPA, State of the students based on semester GPA, and final CGPA. The course codes are 101(c), 102(c), 103(c), 104(c), 105(c), 111(c),112(c), 113(c), 114(c), 115, 201, 202(c), 203(c), 204(c), 205, 211(c), 212, 213, 214, 215, 301(c), 302, 303(c), 304, 305, 311, 312, 313, 314, 315, 401, 402, 403, 404, 405, 411, 412, 413, 414, 415 and detail are available in [11]. However, we have used the courses that are only included in the first four semesters to predict the final CGPA. The courses that are included in the first four semesters ranges from 101 to 215.

V. Data Preprocessing

To solve a real-world problem using machine learning, it is indispensable to preprocess the raw data properly for achieving a better result from the applied model as it directly affects the

ability of the model to learn. Real-world data are generally incomplete, noisy, corrupted, inconsistent, and imbalanced and so it is essential to preprocess the data before feeding it into the model. Data preprocessing is an integral step such as data cleaning, data integration, feature encoding, instance selection, normalization, transformation, feature extraction, and selection. In this study, we have structured this phase according to the form of our dataset which includes missing value handling, feature engineering, feature scaling, feature encoding, data partitioning. All the tasks are discussed briefly in the subsections below.

A. Feature Engineering

Feature Engineering is the process of extracting a new feature subset by utilizing the existing features into formats that are suitable for the machine learning model [12]. We have performed feature engineering techniques to extract the gender of the students based on their name. Also, we have developed new feature columns that indicate the state of the students after completing each of the semesters on the basis of their obtained GPA. According to Table 1, we have used four terminologies namely '*Excellent*', '*Very Good*', '*Good*', and '*At Risk*' to imply the state of the students.

TABLE I
GPA RANGE FOR EVERY DEFINED STATE

GPA	Terminology
3.5 or above	Excellent
3.00 to less than 3.50	Very Good
2.50 to less than 3.00	Good
Less than 2.5	At Risk

B. Feature Encoding

Feature encoding is the technique that represents the categorical data into the numeric form. The neural networks can only learn from the numeric data that is why it is mandatory to encode the categorical data into numbers before feeding the data to the model. In this study, the categorical features that include in our dataset are the gender and the state of the students mentioned above. In order to encode these variables into a compatible numeric form, we have applied the encoding technique named One-hot encoding. This technique generates a binary column for each of the n categories of a categorical variable, where n is the number of unique values contained in that variable [13].

C. Feature Scaling

Feature scaling [15] is a crucial step in the data preprocessing pipeline that is used for data standardization. This includes a few techniques that scale the data into a fixed range to bring all the features to the same level of magnitudes, which suppresses the effect of outliers. It is essential for training a neural network based model as it helps the weights to converge more quickly. For feature scaling, we have applied min-max scaling to each feature column, where the new value X_{sc} of a sample X can be calculated as follows:

$$X_{sc} = \frac{X - X_{min}}{X_{max} - X_{min}} \tag{1}$$

Here, X_{min} is the smallest value in a feature column, and X_{max} is the largest value, respectively. This scaling brings the new value between 0 and 1.

D. Data Partitioning

To properly access the whole dataset, we have applied the training-validation-testing approach in our study. In a neural network model, it is a basic need to tune the hyperparameters and be cautious about the model overfitting and underfitting. A validation set is crucial for properly tuning the hyperparameters and optimize the best model. From the total number of 372 instances, we have used 68% (=261) instances for training, 20% (=66) for validation, and 12% (=45) for testing the model.

VI. Methodologies

In this study, we have maintained a proper workflow for conducting our experiment [14]. The entire workflow basically contains three consecutive steps such as designing the architecture of the DNN model, selecting the evaluation metrics, and defining a baseline performance score for the model. All the implementations of these three steps have been performed using the Python programing language.

A. The Architecture of the DNN Model

DNN models are basically comprised of three major layers: the input layer, hidden layers, and the output layer. The domain-specific architecture of this model can be defined by a few high-level artifacts such as the number of neurons in a layer, the number of hidden layers, the activation function, the optimizer, the learning rate of the architecture, the number of epochs, batch size, and so on. All of these parameters are collectively employed to design a network, and these parameters lead the learning process and the end performance of the model. Thus, it is indisputably a challenging task to select the value of these parameters as they need to be selected with experience and judgment. Fig. 1 represents the visual architecture of our proposed model.

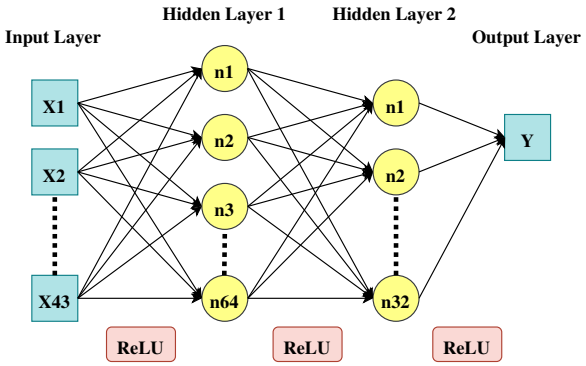

Fig. 1. DNN Architecture.

1) The Number of Neurons in the Input and Output Layers: A neural network architecture begins with configuring the hyperparameters which are the number of neurons in the input and output layer. The value of these hyperparameters depends on the shape of the training data. Our training data has a shape of (261, 43), which means there are 261 instances and 43 attributes. We have specified 43 neurons in the input layer as there are 43 input features in the training data. In contrast, we have specified only one neuron for the output layer as the problem is a regression problem and our expected outcome is a single numeric value.

2) The Number of Hidden Layers and Neurons: Determining the number of hidden layers and the number of neurons in each hidden layer is a crucial task as it characterizes the overall neural network architecture. A study conducted by Jeff Heaton [16] have concluded that networks with a single hidden layer can approximate any function that contains a continuous mapping from one finite space to another, networks with two hidden layers can represent an arbitrary decision boundary to arbitrary accuracy with rational activation functions and can approximate any smooth mapping to any accuracy, and networks with more than three hidden layers can learn complex representations and perform automatic feature engineering. As our training data is not very large, more than two hidden layers will make our model very complex, computationally inefficient, and may cause overfitting to the training data. So, we have designed our neural network architecture employing 2 hidden layers.

Again, to select the number of neurons in the hidden layer, we have applied a rule of thumb from [17]. The book has enunciated that the number of hidden neurons in the first hidden layer should be defined according to the number of input dimensions. If x be the final number of input dimension in a given training dataset, then we should use the nearest number to $2x$ in the power of 2. As our final input dimension is 43, we have employed 64 neurons for the first hidden layer which is nearest to $2x$ in the power of 2. Since the second hidden layer is the last hidden layer before the output, we have employed 32 neurons which the nearest number to $\frac{2x}{2}$ in the power of 2.

3) Activation Functions: Activation functions are an extremely important feature of the neural networks that perform functional mappings between the inputs and response variable. Basically, activation function is a non-linear transformation to the input signal making it capable to learn and perform more complex tasks. After computation, each hidden neuron of a hidden layer generates a single output which is then used as an input in the next layer in the stack. In this study, we have applied the activation function ReLU which is briefly discussed below.

Rectified Linear Unit (ReLU): ReLU [18] is the most widely used activation function while designing a DNN model. If the input is negative the function will convert it to zero and the neuron does not get activated, but for any positive value x, it returns that value back. It is defined as-

$$f(x) = max(0, x) \tag{2}$$

where x is the input to a neuron. So, this is the main advantage of using the ReLU function over other activation functions as it does not activate all the neurons at the same time. Activating a few neurons at a time making the network efficient and easy for computation.

4) Optimization Algorithm: In DNN, an optimization algorithm plays the most important role for obtaining a desirable result from the model. It shapes the neural network model into its most accurate possible form by adjusting the weights and train up model with an optimized cost function. Several optimization algorithms are used in neural networks such as Adam, Gradient Descent, Adagrad, RMSprop, and so on. However, for our experiment, we have applied the optimization algorithm Adam which is briefly described below.

Adaptive Moment Estimation (Adam): The Adam [19] optimization algorithm is an extension to stochastic gradient descent that updates network weights iterative based in training data and works well across a wide range of deep learning architectures. Indeed, this adaptive learning rate optimization algorithm is a combination of gradient descent with momentum and RMSprop algorithms. Adam has some advantages over other optimization algorithms such as it has relatively low memory requirements, invariant to diagonal rescale of the gradients, hyper-parameters have intuitive interpretation and typically require little tuning, and so on.

5) Evaluation Metrics: To evaluate the performance of our proposed model with measuring the error, we have applied three evaluation metrics namely Mean Squared Error, Mean Absolute Error, and Mean Absolute Percentage Error. All the metrics have been elected by considering their benefits and application. The details of these metrics have been discussed below.

Mean Squared Error (MSE): MSE is basically a measure of how close our fitted line is to data points. For each of the data points, it calculates the squared difference between the predicted value and the target value and then averages those differences. The smaller value of this calculation indicates the better fitting of the model. The following equation defines the mathematical formulation of MSE, that is:

$$\frac{1}{N}\sum_{i=1}^{N}(y_i - \hat{y}_i)^2 \tag{3}$$

Mean Absolute Error (MAE): MAE is extensively used for forecasting accuracy where the error is calculated as an average of absolute differences between the predictions and the target values. Basically, it is a linear score which means that all the individual differences are weighted equally in the average. One of the important advantages of this metric is that it penalizes huge errors that not as that badly as MSE does.

Thus, it is not that sensitive to outliers as mean squared error. MAE can be formulated as:

$$\frac{1}{N}\sum_{i=1}^{N}|y_i - \hat{y}_i| \tag{4}$$

Mean Absolute Percentage Error (MAPE): MAPE is a measure of the prediction accuracy that is used as a loss function for regression problems in machine learning. It is a non-scaled error metric and expressed as the relative error preference. For each data points, the absolute error is divided by the target value, yielding a relative error. The main advantage of this measure is its simplicity and it is easy to understand because it provides the error in terms of percentages. Thus, if the average range of the prediction is already known, we can easily estimate what the predictions are going to look like. Mathematically, it can be calculated by the following equation:

$$\frac{100\%}{N}\sum_{i=1}^{N}\frac{|y_i - \hat{y}_i|}{y_i} \tag{5}$$

6) Defining Baseline Performance: Defining the baseline performance is a crucial task to monitor and assess the effectiveness of the neural network model in the training phase. We have considered the performance of a Decision Tree [20] as the baseline for all of the test samples. We have conducted an experiment on our dataset by applying the Decision Tree and the baseline performance we have attained from the decision tree model are Mean Squared Error (=0.02390), Mean Absolute Error (=0.1114), Mean Absolute Percentage Error (=8.0047). To obtain a promising result, our model should offer a performance error less than the baseline error.

VII. Result and Analysis

In this study, we have measured the performance of our proposed neural network model using three evaluation metrics namely MSE, MAE, MAPE. Here, we have applied the MAE as the loss function and have trained our model up to 50 epochs. Fig. 2 presents the losses with respect to the epochs.

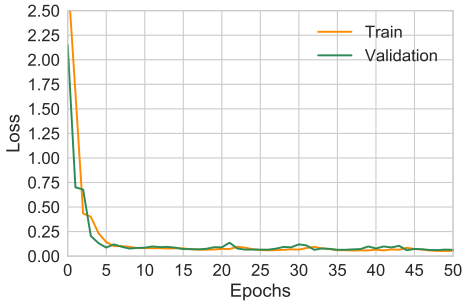

Fig. 2. Train vs Validaion loss across epochs.

The above visualization shows the learning rates of the model over the epochs. It can be apparent that the training and validation losses have been converged at 10^{th} epochs. Here, the validation loss has been quite compatible in converging with training loss indicates a well-fitted model.

After the training and validation phase, we have applied the model on the test data to predict the final CGPA. The test data set have contained 45 instances. Table 2 presents the training, validation, and test result obtained from our model.

TABLE II
Performance of the Proposed Model

	MSE	MAE	MAPE
Training	0.13	0.119	3.536
Validation	0.071	0.116	3.517
Test	0.008	0.067	2.074

From Table 2 it can be observed that the validation result is very close to the training result, which indicates that our proposed model has learned well from the data without overfitting. Interestingly, in all the phases the results are quite compatible with very minimal variations.

In order to grasp the variations in actual and predicted CGPA more expressly, we have visualized all the 45 test cases into a line graph in the following Fig. 3.

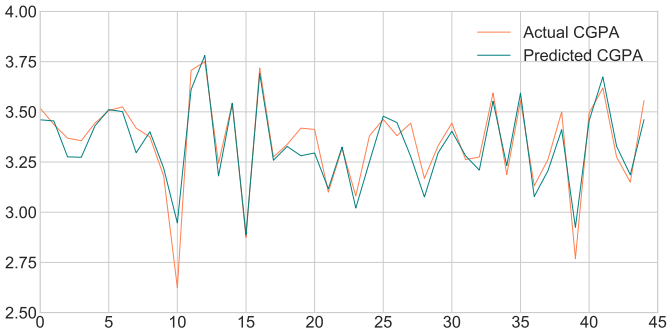

Fig. 3. Actual Productivity vs Predicted Productivity.

From the line graph in Fig. 3 it can be clearly observed that except few points, all the predicted values have a trivial variation with the actual values. For most of the samples, the model have fitted very well and predict the actual value with a minimal error. From all of the above analysis and error metrics we can concluded that our model has learned the underlying pattern from the educational data very well and can promisingly predict the actual CGPA of the undergraduate students.

The following Table 3 shows the comparison between the performance of the baseline model and the proposed model.

TABLE III
Comparison between the Baseline and the Proposed Model

	Baseline Performance (Decision Tree)	Proposed Model Performance (Deep Neural Network)
MSE	0.0226	0.008
MAE	0.1101	0.067
MAPE	8.1168	2.074

VIII. Conclusion

In this study, we have proposed a DNN based model in order to predict the final CGPA of the undergraduate business students with an error rate smaller than the traditional models. The dataset we have used was a real-world dataset collected from a renowned university in Bangladesh. We have performed a bunch of data preprocessing tasks such as feature engineering, scaling, encoding, and data partitioning to prepare our dataset in a suitable form for training the model. In the DNN architecture, we have selected the hidden layers, neurons, optimization algorithm and have tuned the hyperparameters by manual search and practical judgment. The performance of the model has been evaluated by using three evaluation metrics namely MSE, MAE, and MAPE. To examine the training and validation losses, we have used MAE as the loss metric. The training and validation performance of our proposed model indicates that the model has consistently learned from both training and validation data with very less deviation. In the test phase, our proposed model has also yielded very promising result such as 0.008 for MSE, 0.067 for MAE, and 2.074 for MAPE. And, our proposed model have significantly reduced the errors MSE, MAE, and MAPE by 0.0146, 0.0431, and 6.043 respectively than the baseline decision tree model. Most of the predicted points are very close to the true values and our proposed model performance have proved its consistent learning from the transcript data and showed a promising prediction performance.

In our future study, we aim to propose a framework that will be efficiently applicable for the prediction from this type of information. Furthermore, we will also incorporate more attributes such as age, study behavior, study time, family support, and disability for further analysis of the student performance.

***Abstract*—Authorship attribution (AA) is the process of attempting to identify the likely authorship of a given document by analyzing previous works of the authors in question. This paper proposes deep neural network-based continuous skip-gram models for authorship attribution in Bengali Literature. We present a data set of 2400 Bengali blog posts from 6 authors of current time and compare the performances of traditional lexical n-gram based models to our proposed approaches. We achieve a best accuracy of more than 92% on the held-out dataset with a deep convolutional neural network with skipgram word embeddings by fastText as the feature, which outperforms the other traditional models examined in this paper on Bengali Language. The results provide a clear indication that extracting features with the use of hidden layers in deep neural networks from continuous word embeddings work better as a feature set for authorship attribution systems on Bengali Literature than sparse lexical n-gram based features and shallow classifiers.**

***Keywords*—Authorship Attribution, Deep Learning, CNN, RNN, LSTM, skipgram, word embeddings, fastText.**

I. Introduction

One of the traditional classification problems is Authorship Attribution where an arrangement of texts with known authorship are utilized for preparing with an objective to decide the original author of the literary text [6]. The core application zones of authorship attribution include: identification of authors, detection of plagiarism, profiling authors, identification of inconsistencies in the writings of authors. As of late, authorship attribution is used in social media forensics as well to find falsified news sources, detect anonymous online threats and identify fake accounts [16]. Authorship Attribution in highly resrouced languages such as English received a great deal of consideration since the pioneering investigations of Mosteller and Wallace [1963] on the Federalist Papers. However, comparable work of such sorts are extremely uncommon in Bengali, an iconic language amongst the most broadly spoken South Asian languages. This absence of research advancement in Bengali Authorship Attribution could be credited to a lack of sufficient resources such as natural language processing tools and large data sets. [13].
In this paper, we approach the problem of Authorship Attribution with specialised deep neural networks based on word-embeddings. The paper explores some previously used methods and provides a comparative analysis of our approach with the traditional ones. After thorough investigations, we see that Deep Neural Networks, specifically the Convolutional Neural Network in our data set performs the best if implemented with word-embeddings from fastText, providing an accuracy rate of more than 92%. Our experiments give clear indications that word embeddings work as a much better feature than sparse and distinct lexical n-grams in capturing the stylometric patterns of different authors. Deep learning models provide game-changing results, outperforming the shallow classifiers, showing us that the hidden layers in the deep neural networks are capable of extracting the best possible features on their own from the word embedding representations.

II. Related Works

Authorship Attribution has been studied for a long period of time for languages which have the most resources to be worked with. In the initial stages of stylometric studies,

most notable work was done by Mosteller and Wallace. They worked with distribution of 30 function words, words like prepositions, conjunctions, and articles on various federalist papers to identify the original author of those papers[12]. Another notable work that was done by Bogdanova and Lazaridou was focused on cross-language Authorship Attribution. They used books from six different English authors and the Spanish translations of those books and proposed that a starting point to cross-language Authorship Attribution could be machine translation[1]. Zhao et al. [20] obtained impressive results on AP, Gutenberg, and Reuters-2158 corpora by using Kullback-Leibler divergence with Dirichlet smoothing, whereas, Nasir et al. [14] approached semi-supervised anomaly detection via multiple kernel learning for Authorship Attribution. For Authorship Attribution of short texts Sanderson and Guenter [2006] studied character and word sequences and for comparing the performances they used two Markov chain approaches[18]. Sequence kernels of different configuration were applied to a multi-topic data set of fifty authors and the performance was similar to the two Markovian approaches. The results were comparable with character sequence kernels and the results were better than word sequence kernels. The results also suggested that the size of training data had more impact on discrimination power than the amount of test data. It was revealed that if short texts were involved, the unmasking method would be less useful. In 2007 Jonathan H. Clark used synonym-based features for authorship attribution[4]. Bozkurt I. N. et Al. [2] took features like vocabulary diversity, frequency of words like articles, pronouns, conjunctions and bag of words to identify the stylometric patterns of five Milliyet columnist.

In highly resourced languages like German and English, research in the field of authorship attribution has come a long way in recent times. However, the same cannot be said about the progress in Bengali Literature. Up until 2015, only three threads of substantial research was note-worthy in Bengali. Das and Mitra worked studied authorship attribution on a data set of three authors consisting of 36 documents in total [8]. They used uni-gram and bi-gram features along with a probabilistic classification method, which is a variation of the Naive Bayes classification method, where uni-gram delivered an accuracy of 90% and bi-gram, a solid 100%. However, the validity of their experiments come into question due to the fact that the data set was small and the authors had very different styles of writing, making the classification task easier by a large margin. Chakraborty performed a ten-fold cross-validation on three classes showing that Support Vector Machine classifiers can provide best accuracy of up to 84% [3]. Jana looked into Sister Nivedita's influence on Jagadish Chandra Bose's writings which, as intriguing as it is, does not directly concern the topic in question, which is attribution of authors. [10].Since then, Shanta Phani also attempted attribution on three authors using machine learning techniques, much similar to Suprabhat Das's work [15]. P. Das, R. Tasmim and S. Ismail have also investigated the field on four Bangladeshi authors of current time and used lexical features like word frequency, word and sentence length, type-token ratio, number of conjunction and pronoun, etc [7]. Hossain and Rahman developed a voting system with multiple features on an SVM and achieved an accuracy of 90.67% based on lexical and stylometric features. [9]. Taking all the previous works into account, we can clearly see two patterns in the studies that were performed. Most of the approaches were based on shallow classifiers and sparse, discrete features like n-grams. What is also notable is that very little work has been done using deep learning models and the use of word embeddings as text representation is non-existent in the field of authorship attribution in Bengali literature. Our approach consists precisely of the two techniques aforementioned, where we use specialised deep neural networks, such as the RNN with LSTM gates and networks with hidden convolutional layers based on word embeddings as the text representation, based on the consensus that the deep layers of the neural network models will be able to extract the stylometric features held by the word embedding representation.

III. Corpus

A web crawler was developed using python, which collected 2400 articles of six different authors from three online public blogs. To keep the data set as balanced as possible, 350 documents were used per author. To maintain privacy and copyright protection, the authors are code-named FE, HM, IJ, MT, RN, and RG for this paper.

The data set was not normalized or cleaned, leaving it comparatively noisy. The blog texts are also collected from blogs of similar topic and time, making the data set more realistic and difficult for classification. 2100 articles were used for training , while taking 300 documents from the corpus randomly as the testing set.

Author	Total Words
FE	2382241
HM	3372688
MT	2515428
IJ	2401315
RN	1418598
RG	2454574

TABLE I
Corpus Size Per Author

IV. Methodology

The methodology described in this paper is divided into three sections. The first part explains the feature extraction and selection procedures, while the latter describes the classifiers used in the experiments. The third section consists of the performance analysis of our proposed systems on the different feature sets, how they compare with the traditional methods and why they perform the way they do.

A. Feature Selection

1) Shallow Features: With regard to the choice of shallow features, it has been observed that analysis of high frequency words (mostly function, or closed class, words) and/or n-grams provides the most consistently reliable results in stylometry dilemmas.[11] Our data set was consistent with the observations due to it's sparsity and moderate size, providing best results on uni-grams and bi-grams. Thereby, our choice of shallow features for this paper were frequency based embeddings or more specifically,

- count vectors of uni-grams
- count vectors of uni-grams and bi-grams

2) Prediction Based Word Embeddings: Our proposed feature set for this paper was the skipgram model, a type of prediction based word embedding. Given a set of sentences, the model loops on the words of each sentence and tries to use the current word to predict its neighbours, or on from an abstract perspective, its context. Words with similar context are are placed closer in a vector space. The feature was selected based on the consensus that word embeddings that hold context will capture the stylometric features of an author better than independent sparse matrices of uni-grams and bi-grams.

Word2Vec, Glove and fastText are three of the more popular and established algorithms for generating word embeddings. However, in this case of Bengali Literature, a low resource language, our choice tilted more towards fastText due to its ability to represent rare words or words not present in the training set better than the other two. Word2Vec and Glove assign random vector spaces or completely ignore the words that are not in the training data set for representation, which affects performance in Bengali Literature due to the complex structure of the language and unique vocabulary of different authors. While Word2Vec and Glove feed individual words into their own neural networks they use for creating the word embeddings, fastText breaks words into several n-grams(sub words) before putting them into the embedding process. This breakdown of words into numerous n-grams, 3 in our case, means that rare Bengali words, or words not in the training set will now be represented better, since it is highly like that some of their n-grams appeared in some of the words that do occur in the training set. The procedure may not be one hundred percent accurate but shows much better results than just assigning null values or random vector matrices to words.

The continuous word embedding model is mainly extracted to be fed into the proposed specialized deep neural networks, where the dense layers will extract the stylometric features on their own during training.

B. Experimental Setup

1) Proposed Approach: In our approach, we proceed with skip-gram word level embeddings by fastText. Due to a lack of available pre-trained vectors based on a large corpus of words in Bengali we literature, we generate our own vector model based on the held out training corpus. In generating the word vectors, the following parameters were used:

- Vector Dimensions of length 100.
- Context window of 5.
- 5 learning iterations.

The CNN architecture we proposed is a modification of the one used by Collobert et al. [5], who used a CNN with a non-static word embedding channel where the vectors are modified during training using backpropagation. Our approach varies in the sense that the word embedding channel is kept static and the vectors that are pre-trained by fastText's embedding algorithm are not modified during model training.

Initially, the articles of each author are padded to a length of 2000 words, which seemed optimum for the held out data set. The word embedding representations of the padded texts created by fastText on the training data are fed into the input layer. Two more hidden layers are used over the convolutional layer to extract the important features and a feature vector is obtained. A Max-over-time pooling layer [5] in turn condenses this feature vector to its most important feature by taking its maximum value and naturally deals with variable input lengths. A final fully connected layer with softmax activation outputs the probability distribution of the authors present in the data set. The entire model is unrolled for 10 epochs. Hidden states are initialized to 0. The batch size is kept 32. The number of activation per layer is chosen to be 200. An initial learning rate of 1 is used.

The tools and environment setup employed during the implementation are as follows:

- Python 3.5
- Keras
- fastText
- Tensorflow
- NLTK
- Google Colab

2) Comparison Methods: For comparison purposes, we analyze our approach against some methods, most of which are traditionally used.

1) Shallow classifiers with lexical n-gram features
   - a Support Vector Machine with linear kernel and C=1 with n-grams of range 2 as features.
   - A Naive Bayes Classifier with n-grams of range 2 as features.
   - A multi-layered perceptron with n-grams of range 2 as features.
2) Another deep learning architecture
   - A recurrent neural network(RNN) where the word embedding representations of the texts are used as the input to an LSTM layer. Two more hidden layers are used to capture important features, and a softmax output layer delivers the probability distribution of the authors, just like the proposed CNN architecture. All other parameters, such as the static word vectors that remain unmodified during training are kept the same as the CNN approach.

C. Results and Analysis

To analyze the performance of the classification model, the testing data set of 50 articles per author was used. The training and testing data set have no articles in common.

We investigated how traditional classifiers like the Support Vector Machine(SVM) , the Naive Bayes Classifier (NB) and the flat Neural Network(NN) performed on our data set with bi-grams as their input, which showed comparatively decent performances as a feature set on the field of authorship attribution.

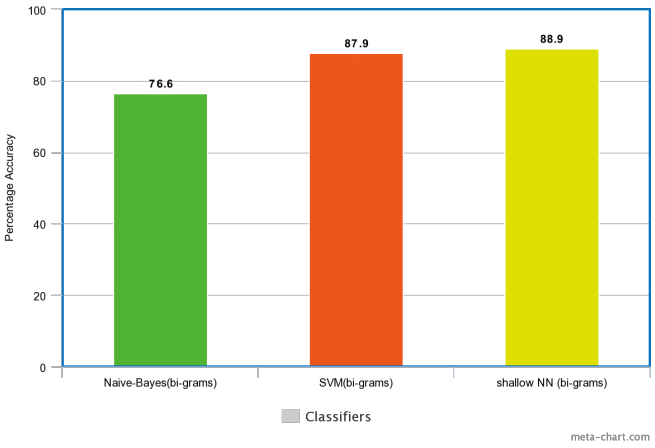

Fig. 1. Accuracy rates of different classifiers on n-gram features

Classifier	Feature	Accuracy
Naive Bayes	n-gram[1,2]	76.6%
Support Vector Machine	n-gram[1,2]	87.9%
Flat Neural Network	n-gram[1,2]	88.9%

TABLE II
PERFORMANCE ANALYSIS OF CLASSIFIERS ON N-GRAM FEATURES

Figure 1 along with Table 2 shows the performance of different classifiers on the shallow lexical n-gram based features.

From the diagrammatic representations, we can see the flat neural network clearly outperforms the other classifiers on the bi-gram feature set, with an accuracy of 88.9%, allowing us to pick neural networks as our choice of classifier for further studies.

Our original approach was to combine deep learning models with word embeddings as features, for which reason we chose to move forward with deep neural networks as they can extract features from the word embeddings very well.For our investigations, we performed separate experiments with a deep Recurrent Neural Network with LSTM gates (LSTM) and a deep Neural Network with a convolutional layer (CNN).

Classifier	Feature	Accuracy
CNN	skip-gram	92.9%
RNN with LSTM	skip-gram	89.6%
Flat Neural Network	n-gram[1,2]	88.9%

TABLE III
PERFORMANCE ANALYSIS WORD EMBEDDINGS AND LEXICAL N-GRAMS AS FEATURES

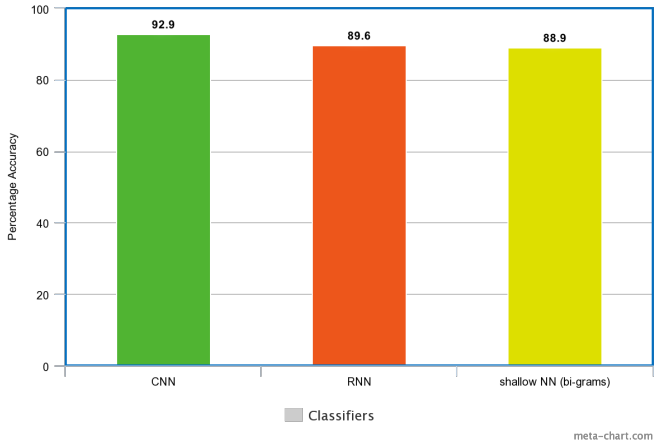

Fig. 2. Accuracy rate comparison of continuous word embeddings and lexical n-gram features with neural networks

Figure 2 along with Table 3 shows the effects of specialized neural networks on word embeddings. The RNN with LSTM gives us an accuracy of 89.67% on the data set, while the CNN outperforms all the previous models with an accuracy of 92.9% on the skip-gram word embeddings.

The RNN with LSTM is one of the very few classifiers that can hold memory, as it takes its previous output as one of the inputs [19]. The LSTM gates help to filter out the less important features, helping the dense layers to extract the features that define the author's styles the best [19].

CNNs are mainly used to process images due to their ability to detect patterns [17]. Sentences also seem to have a dimension, the sequence of words. The CNN in this case seems to capture the context and style of the different authors from the sequence of words very well in this scenario. On the held out dataset, the CNN seems to outperform all the other models , with an accuracy of around 92%.

We can clearly see using deep neural networks to extract stylometric features provides better results than using independent lexical frequency based features with shallow classifiers, as both the deep learning architectures outperform the best accuracy of 88.9% achieved by a flat neural network on bi-grams. The performance boost may be due to the fact the features extracted by well employed deep learning architectures, are at the very least in this case, better than the ones manually extracted. This just goes to show the potential deep learning possesses in the field of authorship attribution due to its ability to capture some of the most relevant and granular patterns in the writing styles of authors that may otherwise be a difficult task to complete manually.

V. CONCLUSION

On the held-out dataset, we have shown that word embeddings clearly outperform the lexical n-gram based features. Best accuracy of more than 92% was achieved with a convolutional neural network based on continuous skip gram word embeddings on our dataset. We believe as the data set size will get bigger, the margin between the accuracy score of

word embeddings and lexical n-gram features will increase. As of future work, we would like to investigate the impact of stacking multiple deep learning classifiers on large data sets. We believe ensembling deep learning models that are different in nature, that is, learn from different types of features, will provide best results.

***Abstract*—Machine learning algorithm suffers to recognize the Bangla handwriting from images because of the complex design, diversities among different writers and similarity between characters and digits. In recent times, deep learning is becoming very popular among the researchers for Bangla Handwriting Recgnition (BHR) because of its high efficiency in terms of memory, time complexity and robust feature extraction. This research aims at improving the performance of baseline Convolutional Neural Network (CNN) by increasing the recognition accuracy with minimizing the computational overhead; this paper presents a real-time Bangla Handwritten Characters and Digits Recognition (BHCDR) system using adopted CNN. Our proposed preprocessing technique, data augmentation and incorporating dropout filters in the baseline CNN architecture have achieved the goal. The proposed eight layered architecture has used two convolutional layers followed by two Maxpooling layers with 25% dropout filters from one layer to another and two fully connected layers with 50% dropout followed by a softmax classifier. The proposed model is trained and tested using 118,698 images of Bangla lekha-isolated dataset and 21000 images of CMATERdb dataset for Bangla hand-written characters and digits maintaining the ratio of 4:1 respectively. The proposed model has achieved the mean accuracy of 97.43% for classification with the average computational costs of 44.95 ms/f.**

***Index Terms*—Convolutional Neural Network (CNN), Bangla Handwriting Recognition (BHR), Data Augmentation, Dropout Filters.**

I. Introduction

Bangla Handwriting Recognition (BHR) has been an area of research interest for a few decades because it has the prospect of saving time and efforts in digitizing important documents like medical prescriptions, official documents. Bangla language or Bengali which is the national language of the people's republic of Bangladesh is one of the most highly used languages as speaking and writing medium throughout the world. Bangla, which is used by 242 million people, is the sixth most used language all over the world [1]. In addition to being the official language of Bangladesh, it is also used as an official language in many states of India where it is the second most used language [2].

Bangla character set is one of the most complex character set because of it's designed complexity. It consists of fifty normal characters. It also consists of 334 compound characters [3] and the ten digits. In our research, we have used 50 characters and 10 digits only. Bangla characters have a complex convoluted structure with high symmetry to one another. There is also high symmetry between many characters and digits of bangla language. Because of this high symmetrical nature and complex convoluted structure of this character set, recognizing the hand-written Bangla characters and digits is a hard task. The difficulty increases multiply when it comes to handwritten character recognition as individual writing habit from each person also add separate complexity.

Among the very early researches on Bangla character recognition, the work of Ray et. al. [4], of Bangla online characters-collected from digitized pen and mouse is mentionable. Later a number of other studies have worked in the same domain and a number of them have adopted the neural network-based approach. In [5] the scholars have normalized the character images at the beginning and then used CNN for the classification task without any feature extraction method achieving accuracy for the training and test sets respectively above 93% and 85%. The work of Roy et. al. [3] have proposed a novel approach of greedy layer-wise supervised training method for deep convoluted neural network and have achieved an error rate of 9.67%. But most of these method suffers from high computational costs. Alom et. al. [6] have proposed a 11 layered CNN model for BHR and have achieved satisfactory results. Their evaluations were compared with a number of methods like Deep Belief Network, CNN with and without dropout, with Gaussian and Gabor filters respectively proved that their system performed better. A very recent research [2] has tried to improve the BHR by modifying Convolutional Neural Network based the ResNet-18 architecture. With an additional dropout layer placed after the second convolutional layer, the researchers are able to produce accuracy up to 94.6% with a boost of nearly 0.5%. More number of layers of the systems [2], [6] have made them more complex in terms of computational costs, feature extraction and recognition accuracy.

This research aims at improving the baseline CNN architecture [6] furthermore by adding additional improvements to increase the classification accuracy with reduced computational

cost. Finally, a comparison with the baseline architecture [6] for Bangla hand-writing recognition is presented. The main contributions of this paper are summarized as follows:

- Modifying the baseline CNN architecture by integrating dropout filters along with Batch Normalization (BN) in our proposed BHCDR to reduce the overfitting for producing more generalized output with regularization which reduces the computational costs.
- The performance of the proposed BHCDR model is improved by including Data Augmentation technique.
- We have added preprocessing module including segmentation, morphological dilation and erosion, Gaussian smoothing filter and finally clipping and normalization to increase the classification accuracy of the proposed adopted CNN model.

The rest of the paper is organized in the following manner: the proposed methodology is described in section II. experiment setup is presented in section III, result analysis is presented in section IV and in section VI conclusion is presented.

II. Proposed Methodology

The proposed model for Bangla hand-written characters and digits recognition (BHCDR) is shown in Fig.1. The proposed model is designed with two phases: First phase is designed for preprocessing and the Second phase is designed for classification using adopted CNN model. The proposed adopted CNN architecture is shown in Fig.2.

A. Baseline Convolutional Neural Network

Convolutional Neural Networks consist of the convolutional layer, pooling layers, and fully connected layer which are stacked entities with identity loops. Each entity or module consists of multiple convolutional layers which correlate its' inputs and map them into the next layer of the CNN including different kernels. The outputs of the kernels pass through the linear or non-linear activation functions ReLU to generate the output of the convolutional layer which is known as feature maps, mathematically represented by Eq.1.

$$In_j^l = f\left(\sum_{i \epsilon Im_j} In_i^{l-1} * K_{i,j}^l B_j^l\right) \quad (1)$$

Where In_j^l represents the outputs of each present layer, In_i^{l-1} is the output of the previous layer, $K_{i,j}^l$ represents the kernel (weight matrix) of the current layer, and B_j^l represents the bias of the present layer and Im_j indicates input map selection. Here, $f(.)$ represents a Rectified Linear Units (ReLU) which is a basically nonlinear activation function. The symbol * is represented as convolutional operator [7]. The MaxPooling function is used to compute the high-level features to reduce the size of features which minimizes the computational cost of the model [8]. The baseline model parameters of CNN consisting of 11 layers for Bangla handwritten isolated digits recognition system developed are listed in TABLE I which was developed by Alom et. al. [6]. Besides, the proposed adopted CNN model is configured as 8 layers are described in TABLE II. The baseline CNN used four convoluted layers, no dropout and Global Average Pooling (GAP) was used as classifier whereas the proposed model has used only two convoluted layers with three dropout filters and two fully connected layers instead of GAP.

B. Preprocessing

The proposed system acquires isolated Bangla handwritten characters and digits images from camera or scanner or pre-stored file in real-time. The system converts these acquired images into binary images. We have used two datasets to train and test the system. One dataset is the BanglaLekha-Isolated dataset [9] and another dataset is CMATERdb [10] (CMATERdb 3.1.1 and CMATERdb 3.1.2 for Bangla hand-written digits and characters respectively). The BanglaLekha-Isolated dataset which is already preprocessed as binary images where characters are converted to white and its background is converted to black. Another dataset CMATERdb is also preprocessed but its characters are black and the background is white. So, the system needs to invert the images of CMATERdb dataset to make as similar to the BanglaLekha-Isolated dataset. After that, morphological dilation and erosion operations are applied followed by Gaussian smoothing filter to make it noise free and robust dataset [11], [12]. All dataset are already resized in a square shape with appropriate padding [2]. We have used clipping and normalization technique [11] on the resized data to convert these into a fixed size 32×32.

Algorithm 1: Proposed algorithm for adopted CNN model execution for BHCDR

Data: 32×32 image.
Result: 60 classes of Bangla hand-written characters and digits.

```
begin
    Apply ADAM (δ = LearningRate = .002);

        SoftMax (Classes, KernelInitializer);
    end
end
```

C. Proposed Adopted CNN model

The proposed adopted 8 layered CNN architecture is shown in Fig.2. Each entity or module of the proposed model takes input In and generates $F(In)$ output pairs which are then added to the input In of next convolutional layers. The resulted new input is represented by Eq.(2).

$$F(In) = F(In) + In \tag{2}$$

In our proposed model, dropout [13] layers are added after the first MaxPooling (MP1) and second MaxPooling (MP2) layers. Another dropout layer is also added in front of the second fully connected layer (FC2). Many researchers have used dropout to prevent feature adaptation and overfitting as a substitution of batch normalization (BN) [14] in their proposed model having a large number of parameters. Although another model [2] has used dropout along with BN which also performs better in generalization. Motivated by their approaches, we have applied the dropout along with BN in our proposed model. All dropout layers are added to reduce the overfitting for producing more generalized output with regularization. As a result, the proposed system ensures to minimize the overall computational costs.

The first layer of our proposed adopted CNN model is input layer which is connected with the first convolutional layer (Con1) containing a 5×5 kernel which has 32 filters and 1×1 stride size with a BN and ReLU activation function according to the Eq.3.

$$ReLu(In) = Max(0, In) \tag{3}$$

The first convolutional layer takes input as 32×32 pixels images. Next Max-Pooling layer (MP1) containing 2×2 kernel with 32 filters that uses maximum value to reduce significantly the number of parameters and computational costs in the network. This MP1 layer also controls the overfitting. Then the dropout layer (DR1) is configured with 25% (based on fine-tuning the model for different values) of neurons are excluded to reduce overfitting. The next hidden layer of the proposed model is another convolutional layer (Con2) containing a 3×3 kernel that has 64 filters and 1×1 stride size with a BN and ReLU activation function as like as Eq.(3). The second convolutional layer (Con2) is followed by another Max-Pooling (MP2) and 25% (based on fine-tuning the model for different values) dropout layer (DR2). A Flatten layer (FL) is used in this stage to convert the two-dimensional matrix data to a vector followed by a fully connected layer (FC1) with ReLU activation function and 50% (based on fine-tuning the model for different values) dropout layer (DR3) to obtain the final output to be processed next layers. The first fully connected layer (FC1) contains 256 neurons. The second fully connected layer receives the previous 256-dimensional output of the first fully connected layer (FC1) containing 64 neurons with the ReLu activation function which has 128 neurons. The final part of the proposed adopted CNN model is the Softmax activation function which is activated by Eq.(4) for final output layer containing 60 neurons for 60 classes of Bangla hand-written characters and digits.

$$f(In_i, W) = WIn_i \tag{4}$$

Where, f is defined as a mapping function that takes an input dataset In_i and produce them to the output classes as WIn_i which represents the dot product of the input dataset In_i and weight matrix W.

Inspired by [15], data augmentation is applied on both online and offline datasets to improve the model generalization and overfitting during the training phase. The system augments input datasets during the training phase by applying only rotations and translations operation. By using this rotation operation, the training datasets are increased 10 times in which the system rotates and translates the dataset 1% and 0.5% in each step respectively. All of these operations are applied randomly inside the mini-batches from scratch that are fed into the network. By training the shape and appearance of stream networks, the proposed model helps to converge faster. Incorporating the augmentation technique and dropout filters to the proposed model ensures that the proposed system is able to minimize computational costs by keeping higher classification accuracy.

Finally, the proposed model is executed according to the configuration listed in TABLE II using Algorithm 1. We have experimented using Adam [16] optimizer in the proposed Algorithm 1 with a learning rate of $\delta = 0.002$ (based on fine-tuning the model for different values of δ) to find the global minima of the categorical cross entropy loss function. Adam optimizer is memory efficient and computationally faster. More specifically, according to the experimental result of the system [2], Adam optimizer performs better than both Root Mean Square Propagation (RMSProp) and Stochastic Gradient Descent (SGD) optimizers.

III. Experimental Results

In our experiment, the proposed model for Bangla hand-written characters and digits recognition uses an ASUS UX305C model Notebook PC. The configuration of the experimental platform is specified as Intel Core m7 CPU and 2GB RAM. We have conducted an experiment on Microsoft visual studio 2010 and EmguCV (C and OpenCV wrapper) in Windwos10.

A. Datasets preparation

The proposed model is trained and tested using two datasets named BanglaLekha-Isolated dataset [9] and CMATERdb [10] (CMATERdb 3.1.1 and CMATERdb 3.1.2 for Bangla hand-written digits and characters respectively) dataset. The BanglaLekha-Isolated dataset contains 84 classes where 50 classes Bangla alphabet and 10 classes are Bangla digits (0-9) and 24 classes are joint letters. The CMATERdb dataset contains 231 classes of Bangla hand-written alphabets and digits images where 50 classes are alphabets (vowel and consonants) and 10 classes are digits and the other 172 classes are joint letters. In our experiment, we have used only 50 alphabet classes data and 10 Bangla digit classes data from both datasets.

Fig.3 shows the example training dataset- where class 01 to 50 are representing Bangla hand-written characters dataset including Bangla vowels (class 01-11) and consonants (class 12-50) and class 51 to 60 are represent-

ing Bangla digits. The BanglaLekha-Isolated dataset contains total (98,950+19,748)=118,698 images of Bangla alphabet and digits, and CMATERdb dataset contains total (15000+6000)=21000 images of CMATERdb 3.1.2 for Bangla hand-written 15000 characters and CMATERdb 3.1.1 for Bangla 6000 digits. We have used randomly selected about 4:1 of these both datasets for training and testing. According to the ratio, 94,958 images have been used as training dataset and 23,740 images have been used as testing dataset among 118,698 images of Bangla lekha-isolated dataset. Similarly, 16200 images have been used as training dataset and 4200 images have been used as training dataset among 21000 images of CMATERdb dataset.

B. Perfomance Mesurement Parameters

To evaluate the performance of the proposed Adopted CNN model and the baseline CNN model [6] we have used two parameters such as Accuracy and computational costs. Accuracy is calculated using Eq.(5).

$$accuracy = \frac{TP + TN}{TP + TN + FP + FN} \tag{5}$$

Where TP is the true positive, TN is the true negative, FP is the false positive and FN is the false negative which are measured from the confusion matrices that are not presented here due to saving space and simplicity.

The computational cost for the real-time system is calculated based on the time it takes to preprocess, extract features using convoluted layers and classify a single test image of Bangla hand-written characters and digits against the training dataset in milliseconds per frame (ms/f).

C. Performance Evaluation

Fig.4 shows the accuracy for different 60 classes of Bangla hand-written characters and digits recognition using proposed

Fig. 3. Example training dataset.

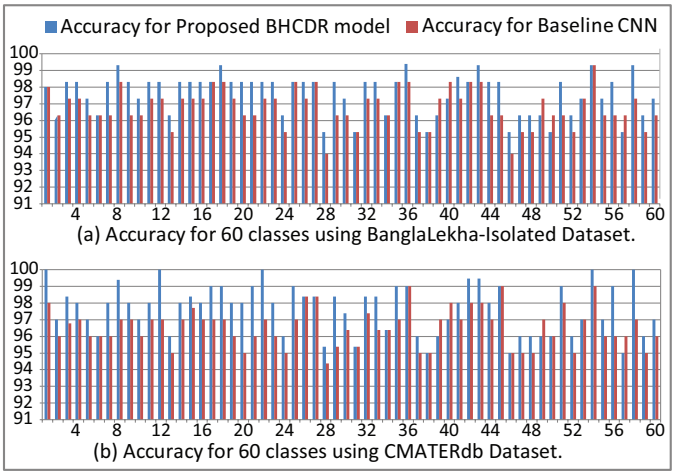

Fig. 4. Accuracy rate for different 60 classes of Bangla hand-written characters and digits recognition using proposed BHCDR model for (a) BanglaLekha-Isolated dataset and (b) CMATERdb Dataset.

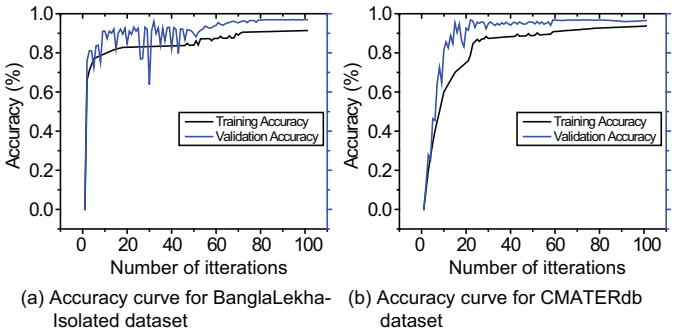

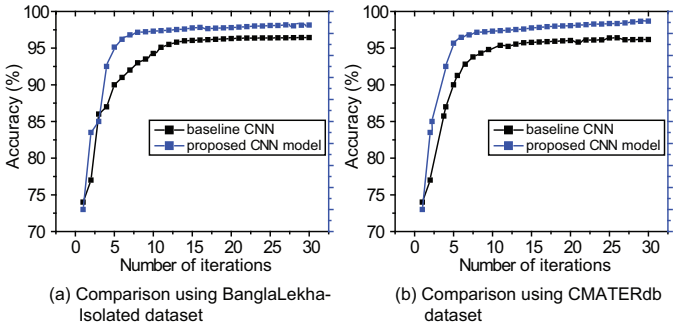

Fig. 5. Training and testing validation accuracy versus iterations curves for performance analysis of the proposed BHCDR model using (a) BanglaLekha-Isolated Dataset and (b) CMATERdb dataset.

BHCDR model comparing with the baseline CNN architecture [6] for BanglaLekha-Isolated dataset and CMATERdb Dataset. It is evident that the proposed system performs correctly and more accurately than the baseline model [6].

Fig.5 shows the training and validation accuracy curves for the proposed BHCDR model using both datasets. From this analysis, it is shown that the training and validation performances are close to each other for different iterations using both mentioned datasets which proves that the proposed BHCDR model is not overfitting the data.

The TABLE III shows the comparison of classification accuracy of the proposed model and baseline model. We have evaluated mean accuracy and computational costs for the proposed model and baseline model using both datasets of BanglaLekha-Isolated dataset [9] and CMATERdb [10]. The baseline CNN model [6] achieves 96.51% mean classification accuracy with the average computational costs of 89.27 ms/f. Our proposed model of CNN achieves 97.43% mean classification accuracy with the average computational costs of 44.95 ms/f which is relatively better than the baseline model [6]. The baseline model developed by Alom et.al. [6] have achieved

(a) Comparison using BanglaLekha-Isolated dataset

(b) Comparison using CMATERdb dataset

Fig. 6. Comparison analysis graph for the proposed BHCDR model with baseline CNN model using (a) BanglaLekha-Isolated dataset and (b) CMATERdb dataset.

TABLE III
COMPARISON ANALYSIS WITH RESPECT TO ACCURACY AND COMPUTATIONAL COSTS BETWEEN PROPOSED BHCDR MODEL AND BASELINE CNN ARCHITECTURE USING DATASET-1 (BANGLALEKHA-ISOLATED DATASET) AND DATASET-2 (CMATERDB DATASET)

dataset	accuracy (%)		cmputational cost (ms/f)	
	BHCDR	basline CNN	BHCDR	basline CNN
dataset-1	97.28	96.5	44.98	89.28
dataset-2	97.58	96.52	44.92	89.26
mean	97.43	96.51	44.95	89.27

99.13% average accuracy by experimenting their system for Bangla hand-written characters and digits dataset separately. But we have used both characters and digits datasets in a single experiment by assigning the class labels 01 to 60 which increases the confusions and reduces the accuracy due to similarity among characters and digits datasets.

Fig.6 shows the comparisons of classification accuracy between the proposed model and baseline model considering 30 iterations. Although the comparison graph has reached the optimal accuracy from 10 iterations, we have evaluated 20 more iterations for better compatibility. The comparison results prove that the proposed model performs two times faster than the baseline model with keeping higher classification accuracy.

The implementation of data augmentation technique in baseline CNN architecture improves the performance of the proposed BHCDR to achieve much higher recognition accuracy than the baseline CNN model without overtraining.

IV. CONCLUSION

This paper proposes real-time Bangla handwritten characters and digits recognition (BHCDR) using adopted convolutional neural network. The datasets are used in these experiments vary in different angles, sizes, contrasts, noises, and translation. Data augmentation technique is done on the dataset that generates transformed images of datasets and increases the training dataset instead of overtraining that ensures the robustness of the proposed model. Our preprocessing steps and introducing the dropout filters in the modified CNN model enhanced the performance of the proposed BHCDR by eliminating the data overfitting. The proposed model is trained and tested using 94,958 and 23,740 images of 118,698 BanglaLekha-Isolated dataset and 16200 and 4200 images of 21000 CMATERdb datasets respectively. The system has achieved 97.43% mean accuracy with the computational costs of 44.95 ms/f which is comparatively two times faster than baseline CNN model [6] with keeping higher classification accuracy. With this improvement, the proposed BHCDR results described that the proposed model is an effective CNN model for Bangla handwriting recognition. Future work of this research will extend and evaluate the proposed adopted CNN model with other compound characters datasets. The proposed system can be applied for automatic vehicle number plate recognition, postal code recognition, bank check recognition, any hand-written document digitization and so on.

***Abstract*—Rice is one of the most extensively consuming staple foods over the world. But due to various diseases of rice, farmers can't yield rice according to their expectation. Therefore, the quality, quantity and production of rice are being interrupted. It is difficult for the farmers to diagnose diseases, because of the lack of knowledge and unavailability of professional specialists. It also requires much time in manually identifying and classifying rice diseases. Therefore, an automated and accurate identification system has become essential to overcome this problem. A unique and fruitful approach has been presented to detect rice diseases with the implementation of an artificial intelligence (AI) and computer vision technologies. Here an AI has been developed by combining a Deep Convolutional Neural Network (DCNN) with Support Vector Machine (SVM). The Inception V3 DCNN architecture model has been modified using transfer-learning method. Then DCNN has been retrained with more than 1080 images of nine different rice diseases which are 80% of the image dataset. The features, extracted by the retrained DCNN was then used to train the SVM classifier. The network efficiently classified the images of nine diseases with an accuracy-level of around 97.5%.**

Keywords—Rice disease identification, Computer Vision, Artificial Intelligence, Deep Convolutional Neural Network (DCNN), Inception V3 model, Transfer learning, Support Vector Machine (SVM).

I. INTRODUCTION

In Bangladesh, rice is the major food of about 135 million peoples. Rice cultivation provides about 48% of rural development, it also contributes two-third of total calorie supply. An individual person can gain about one-half of the total protein requirement from rice. Over the past three decades rice is cultivated on about 10.5 million hectares which has remained almost stable in the meantime. About 75% of the total cropped area and over 80% of the total irrigated area is cultivated with rice [1]. Thus, rice plays a vital role in the livelihood of the people of Bangladesh as well as in the Asian countries. But the quality as well as the quantity of the rice production may be degraded due to plant diseases. As having diseases in plants are quite natural. If a proper step is not taken in this regard then it causes serious effects on rice plants which affects respectively product quality, quantity and productivity. These diseases are caused by pathogens such as fungi, bacteria, viroid, nematode and viruses. Typically, these pathogens damage the photosynthetic apparatus and affects the growth of plant [2]. Therefore, it is the major task to identify and classify rice plant disease in early stage [3].

At present, farmers use their own experience to detect diseases. Without recognizing plant diseases, farmers use pesticides in excessive quantities, which can't help in the prevention of disease, but can have malignant effects on plants. Though some rice diseases can create similar lesions or spots area and also different spots could be created from same diseases because of different rice diversities and local conditions or weather [4]. Thus, sometimes their misclassification creates bad impact on rice cultivation. So, they need an advice from rice disease specialist. In remote or rural areas, rice disease specialist can't able to give quick remedies or advice to the farmers in the right time and they also require expensive equipment and large amount of time for manually identifying and classifying rice diseases. On the other hand, for manual data processing requires more eyes to check and double check data for its accuracy. While an automated system identifies and classify diseases affected images more accurately than manually identifying process.

To overcome this problem, the process could be automated with the implementation of artificial intelligence (AI) and computer-vision technologies. For this reason, a hybrid network has been proposed by combining deep convolutional neural network (DCNN) with support vector machine (SVM) to classify rice diseases. This process could be made faster and easier when both time and human-efforts are saved significantly. To reduce loss function, a gradient based algorithm has been used by multi-layer architecture such as

DCNN [5]. In recent years, Convolutional Neural Network (CNN) is also used to analyze diseases of tea [6], apple [7], tomato [8], grapevine, peach, and pear [9]. It has also shown phenomenal accuracy in classifying and detecting that diseases. Deep convolution neural network is also used for achieving higher accuracy [10]. On the other hand, SVM is a classifier that learns a training dataset using properly chosen kernel parameters [11]. Combination of CNN and SVM has also been implemented recently for high dimensional data processing and classification such as visual pattern recognition [12] and image classification [13]. Thus, we were influenced to develop an AI by combining DCNN and SVM for the classification of rice diseases.

The proposed method represented a system to classify the disease of rice plants and assists the farmers to take exact calculation and also aid to increase the production. In this paper, for the classification of images of rice disease, we developed a hybrid network by combining both DCNN and SVM. A pertained Inception V3 DCNN model [14] was first modified and then retrained with a train-dataset containing more than 1080 images of nine rice diseases using transfer learning method. Then the retrained DCNN model automatically extracts one-dimensional features from the images that are used to train SVM classifier. The complete network is then tested on a test-dataset of 270 images.

The paper has been divided into six sections. In section II, various detection techniques of diseases of rice crops are reviewed. Section III presents the dataset preparation stage. Section IV explained the proposed modified Inception V3 DCNN architecture with SVM classifier to extract feature and classification respectively along with the results and discussion are illustrated in section V. Conclusions are summarized in section VI.

II. Related Work

A number of approaches have been already employed to accurately identify or classify plant diseases from images. Most of them used general image processing techniques, SVM classifier, K-means clustering, Neural Network (NN) and so on.

A pattern recognition based identification system of rice disease has been investigated by Phadikar et al. [15]. They used Self Organizing Map (SOM) neural network for classifying rice diseases. To normalize the size of disease spot, fractional zooming algorithm has been employed & images are segmented by Hue Intensity Saturation (HIS) model. In this paper, the authors considered two rice diseases named leaf blast and brown spot.

Another work has been done in [16] where they proposed an automated system based on the morphological changes for the classification of rice disease using Bayes & SVM classifier. They proposed two approaches to classify rice leaf diseases: (1) between infected and healthy leaves and (2) among infected leaves. They acquired 79.5% and 68.1% accuracies for Bayes and SVM classifier based system respectively.

In 2009 Yao at el. [4] developed an automated rice disease detecting system by presenting image processing techniques and SVM. They operated Otsu Method for the segmentation of disease spots. From Gray level co-occurrence matrix (GLCM), texture features were adopted to classify three (rice bacterial leaf blight, rice sheath blight and rice blast) disease of rice plants and SVM based function namely radial basis kernel function was selected for identifying these diseases. They earned overall 97.2% accuracy.

A computer vision based approach has been suggested by Ghyar et al. [17] for the detection of rice leaf disease. They considered only two disease of rice which are leaf blast and brown spot. Area of disease, GLCM and color moments are those extracted features. Artificial NN and SVM are used for classification of two diseases as well as healthy leaves. For getting higher accuracy, they employed K-means clustering for image segmentation.

To classify rice disease images, in this paper [18], non-linear SVM classifier using RBF kernel has been applied. Leave One-Out cross validation method was considered for the assurance of what training data could be learned about the applied method. Here they used Principal Component Analysis (PCA) technique for reducing pixel data from 3-dimension to two-dimension.

Recently, a deep convolutional neural networks (DCNN) based work was proposed by Lu et al. [19] to identify rice diseases by considering 10 common diseases for identification. A CNN model has been used to obtain a higher recognition accuracy and for the improvement of the convergence speed of the trained parameter. The older deep learning frameworks namely LeNet-5 and AlexNet were used as CNN architecture model for detecting diseases. They used around 500 image samples. Though, this small dataset was not quite enough for the classification of 10 rice diseases when it comes to deep convolutional neural network. Nevertheless, the author claims to achieve 95.48% accuracy.

Another DCNN approach has been taken in [20], where the authors developed a system that can recognize rice leaves by its health status. They used three classes in total which included normal, unhealthy and snail infested rice plants. For the classification they employed an old AlexNet architecture model of DCNN and claim about 91.23% accuracy. Although, they didn't mention any specific diseases or classes of rice for the classification. The proposed model only can tell that it is affected by diseases or not. Considering all these issues, we have presented nine most commonly affected rice diseases image classification by combining DCNN with SVM classifier which gave higher accuracy.

III. Dataset Preparation

The task of preparing dataset consists of two steps: assortment of disease images and pre-processing.

A. Assortment of disease images

We collected images of disease of rice plants from our varsity rice research field under the supervision of a professor and also some online resources named IRRI [21], BRRI [22], BRKB [23], Plantix [24] and so on.

Here we considered nine different diseases of rice which are most commonly affected diseases mainly in Bangladesh as well as other countries. These are- Bacterial Leaf Blight, Rice Blast, Brown spot, False Smut, Leaf Smut, Red Stripe, Leaf Scald, Sheath Blight and Tungro. Generally, the color, shape & size of Rice blast disease depending on varietal resistance, environmental conditions and the age of the lesions [25]. Rice blast mostly attacks in these two organs of the rice plants and

those organs are- Leaf and Collar, and Neck and Node. Though we put these two affected organs in same class but we trained them separately. A catalogue is presented in Table I that includes the name of those diseases and disease area for which they are liable.

TABLE. I

SELECTED DISEASES FOR CLASSIFICATION

Disease Image	Scientific Name	Disease Name	Affected Areas
	*Cochliobolus miyabeanus*	Brown Spot	Leaf blades and glumes
	*Ustilaginoida virens*	False Smut	Rice grain
	*Xanthomonas oryzae*	Bacterial Leaf Blight	Leaf
	*Microdochium oryzae*	Leaf Scald	Leaf
	*Entyloma oryzae*	Leaf Smut	Entire leaf surface
	*Microbacterium sp.*	Red Stripe	Leaf
	*Rhizoctonia solani*	Sheath Blight	Leaf sheath
	*Rice tungro bacilliform virus*	Tungro Virus	Leaf
	*Magnaporthe oryzae*	Blast	Leaf and collar or neck and node

B. *Pre-processing:*

For the classification process, image pre-processing task plays a vital role. The main purpose of this section is to improve the quality and quantity of images of the dataset. Feature extraction performance of CNN mostly depends on the quality, diversity and numbers of image samples. Therefore, the purpose of pre-processing task is to escalate the number of image-samples without reducing image quality or resolution. Therefore, we manually crop those large images containing numerous samples and raise the number of images.

Then all images are rescaled to 299px square size, which is required by Inception V3. Finally, the images go through an augmentation process that involves random flipping and vertical or horizontal translation up to 10 pixels. Thus, the number and variety of samples are increased and the unnecessary edges are removed as well. An example of manual-cropping process implemented on a disease image samples is represented in Fig. 1.

(a) (b) (c) (d)

Fig. 1. Manual cropping process of a sample image.

IV. METHODOLOGY

The biggest advantage of using DCNN is the perfection in extracting invariant features. But it is not always perfect as a good image classifier due to most of the trainable parameters are tuned in the hidden layer. On the contrast, SVM tune very few parameters to provide high classification accuracy for perfectly extracted one-dimensional feature vector, though it fails to learn very complicated features due to nits fixed kernel parameters [26]. Therefore, we have used Inception-V3 DCNN model with a non-linear SVM classifier to create a hybrid network in order to achieve high prediction accuracy for classifying rice disease images. The complete procedure of predicting rice diseases sample is therefore separated into two sections: feature-extraction and classification.

A. *Feature-extraction:*

Feature is an important and unique property of an image. To find out these relevant features from an image using a suitable algorithm means feature-extraction. Accurate feature selection approach enhances the classification speed, accuracy and reveal to train a classifier with large amount of data. In feature extraction, we can obtain the most relevant information from the original data and represent that information in a lower dimensional space. So Feature selection is an important post processing step, since a classifier will not be able to recognize images from poorly selected features.

Here the principal advantage of CNN is that we don't need to manually extract features from images. CNNs are able to automatically learn to extract complex hierarchical features from an image by using different kinds of filters during training time.

One of the deepest and complex DCNN architecture is Inception-V3. To perform, classification of each image Inception-V3 model uses nearly 25 million parameters and 5 billion multiply-add and floating-point operations [12]. But it is not generally affordable for one individual to train such a huge network efficiently due to it requires massive amounts of data, more time and multiple GPUs and TPUs. Therefore, the transfer learning [27] method comes into play, which is the recycle of a pre-trained model that permits us to partially use its weights on our network. Thus, it reduces the required training-time and decreases computational complexity as well. The pre-trained Inception-v3 model trained with more than 1 million images to achieves state-of-the-art accuracy for recognizing general objects with 1000 classes [28]. The Inception V3 of the model has 316 layers where we kept frozen initial 42 layers (up to 'mixed0' layer) to prevent them

from updating weights. The rest of the layers were retrained with disease images of rice plants. The number of iterations performed by the retraining process is calculated from equation (i).

$$\text{Number of Iteration, N}i = (Ns/Bs)*Ne \ldots\ldots (i)$$

Here Ns represents the number of samples, Ne represents the number of epochs and Bs is for batch-size. The batch-wise training accuracy is increased through back-propagation process that reduces error-rate significantly after several iterations. The complete model architecture is shown in Fig. 2.

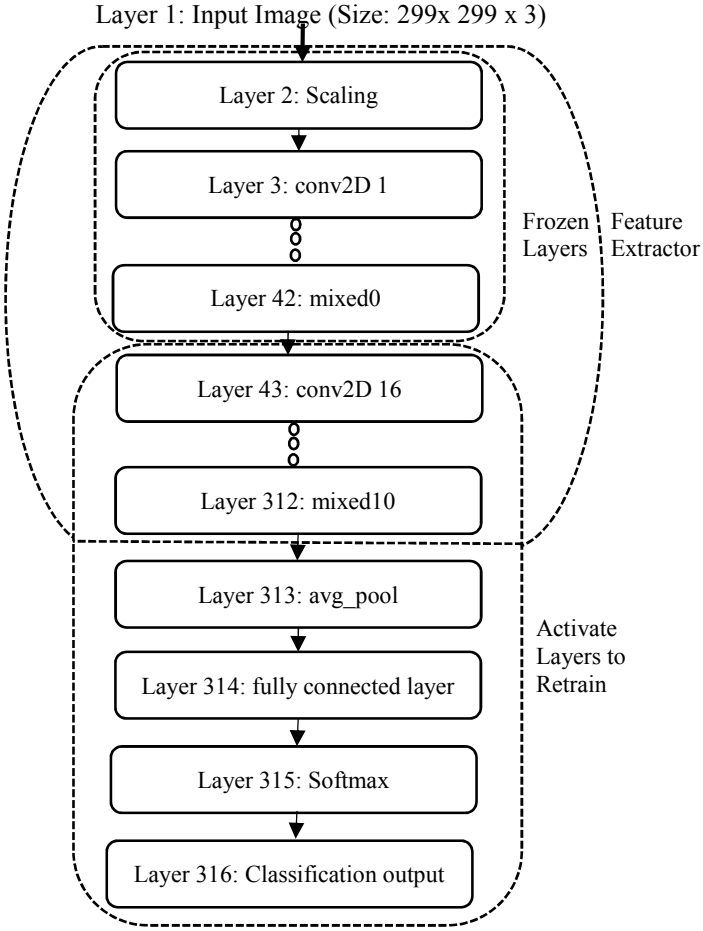

Fig. 2. Architecture of the modified Inception-V3 DCNN model.

Once the DCNN model is retrained, we eliminated its last 4 layers containing average-pool, fully-connected layer, softmax classifier and output layer. The rest of the network was then used for extracting features from rice diseases images.

B. *Classification:*

In classification stage, all extracted features from DCNN model are flattened by using 'global average-pooling' function. For future use the one-fifth features are separated. Then we train Support Vector Classifier (SVC) as a multi-class classifier with all rest of the features using one-VS-one method and it was implemented with RBF kernel. The hyper parameters of SVC classifier such as 'gamma', cost parameter 'C' were tuned using grid-search algorithm. Finally, the classifier was used to predict the previously separated features and calculated the validation accuracy. The complete process is represented as a block-diagram in Fig. 3.

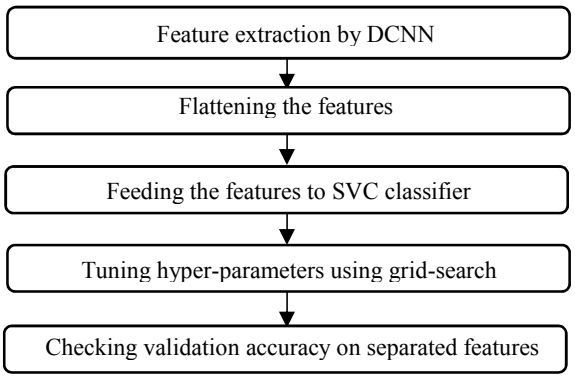

Fig. 3. Steps of training SVM classifier

Thus both DCNN and SVM models get trained for feature extraction and classification respectively. Now the hybrid network is ready to predict image of rice diseases.

V. Result and Discussion

This paper is experimented in two phases: Training Phase and Testing Phase. The complete process of training and testing was rendered on a personal computer (CPU: Intel core i7 @ 3.6GHz 64-bit, RAM: 8.00 GB and free-space on SSD: 100 GB) with 'Windows 10' operating system. We collected a dataset of images of rice plant disease including nine most commonly affected diseases. For training phase, we used 80% samples or images of the dataset to train the hybrid network and which is nearly 1080 images of disease. In order to validate the DCNN model, nearly 216 images are separated which is 20% of the training dataset. As, our target is to achieve high accuracy in extracting invariant features of rice diseases by using DCNN model. Therefore, in feature extractor section the value of active-layer's learning-rate was set to very low at 0.0001. Ultimately, the train and validation accuracy of DCNN model is tested for separate combinations of epochs and batch-size, which is shown in Fig. 4.

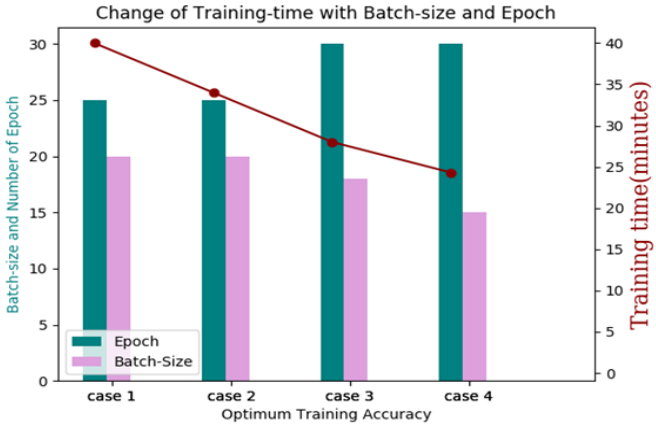

Fig. 4. Change of batch-size and epochs to reduce training-time

In Fig. 5, there are four cases representing four different combinations of batch-size and epochs. Validation accuracy for each of these cases were above 93%. Here case 4 combination (Batch-size: 30 and epoch: 15) required the least

training-time of 24 minutes 30 seconds. Thus, the training-time was reduced by around 18 minutes from case 1 to case 4, while the validation accuracy was reduced by only 2%. Now, the final values of all training-parameters of DCNN model, and hyper-parameters of SVM model are represented in Table II.

TABLE II

FINAL VALUES OF ALL USER-DEFINED PARAMETERS

DCNN		SVM	
Parameter	***Value***	***Parameter***	***Value***
Learning-rate of active layers	0.0001	Kernel	RBF
Batch-size	30	C	100
Number of epoch	15	Gamma	0.0001
Number of frozen layers	42	_	_

The graphical presentation of the training process was recorded while the DCNN model was retrained with the fixed user-defined parameters. It shows training and validation accuracy as well as training and validation loss, which are shown in Fig. 5 and Fig. 6 respectively.

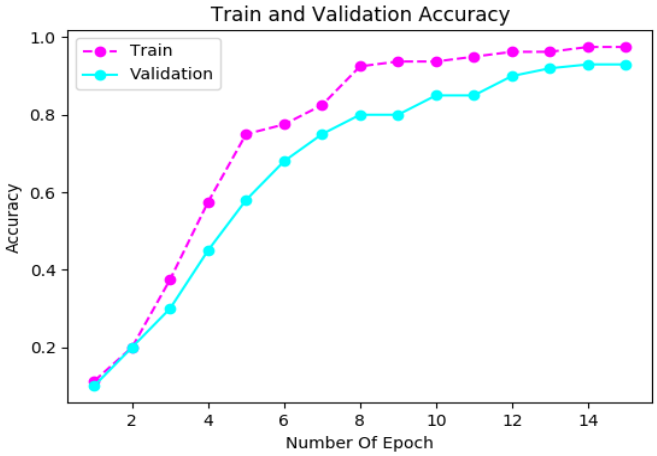

Fig. 5. Train and validation accuracy with respect to the number of epochs.

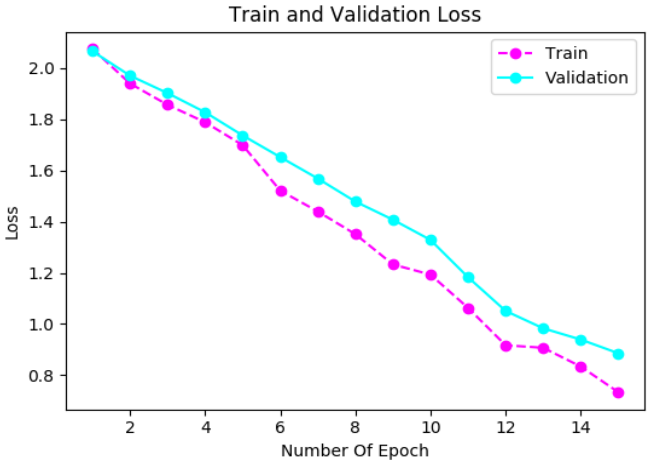

Fig. 6. Train and validation loss with respect to the number of epochs.

From Fig. 5 and Fig. 6, it has been observed that, during the last 4 epochs, both train and validation accuracy were above 93% and both train and validation losses were reduced below 1 respectively. The hybrid network with tuned SVM parameters was finally tested on the test-dataset of 270 samples, where it was achieved prediction accuracy of 97.5% and 94.6% in CNN-Softmax combination. In terms of CNN-Softmax combination, it needs massive amount of data to properly adjust model weights through back-propagation. But the combination of DCNN-SVM works well on small dataset for perfectly classifying an image due to its kernel trick. Therefore, the combination of DCNN-SVM has been used in this proposed model. Several classification results are shown in Fig. 7.

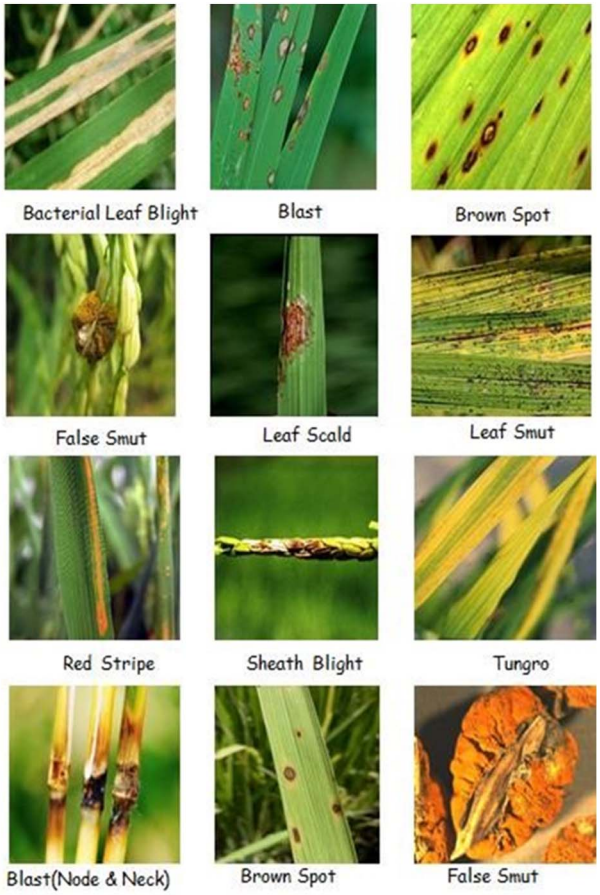

Fig. 7. A few results of classifying test-images of rice disease.

VI. CONCLUSIONS

Identification & classification of rice disease is quite impossible for farmers by naked-eye. It requires a significant amount of time, human effort and professional expertise. Hence, an effective approach has been taken to automate the process of classifying and identifying disease from images of rice plants. In this paper, the proposed method was aimed to develop an automated system to classify images of rice plant disease with the implementation of artificial intelligence and computer vision technologies. We represented a hybrid model by combining DCNN and SVM for the classification of rice diseases. The Inception V3 DCNN model was used for the automatic feature extraction. Supervised learning classifier SVM with RBF kernels was used for the classification of images of rice disease. We considered nine diseases of rice plants which are most affected diseases. Then

we built an image dataset of rice diseases. 80% of the dataset was used for training purpose and we achieved 97.5% prediction accuracy in training phase. This proposed model successfully classified a test-dataset of 270 images of rice plant diseases. Therefore, this proposed method has been made completely automated for the classification of rice diseases.

ACKNOWLEDGEMENT

The authors would like to thank Dr. Md Mamunur Rashid, Professor at Department of Plant Pathology, Hajee Mohammad Danesh Science & Technology University (HSTU) for providing valuable information and image database and also full support in order to prepare this paper.

Abstract*—At present, mobile apparatuses are becoming increasingly sophisticated and the latest generation of Smartphone that incorporates many diverse and powerful sensors such as linear or tri-axial accelerometer, linear or tri-axial gyroscope, Global Position System a.k.a. GPS etc. The availability of these sensors in mass-marketed communication devices creates new exciting opportunities for data mining and machine learning approach; besides creates a new research arena for Human Activity Recognition a.k.a. HAR. Wireless sensor based HAR has a significant impact on monitoring diseases related to ambulatory assessment, physical activities, elderly care, sports science, physical therapies and so on. The aim of this exploration is to recognize ten human activities stated as walking, walking upstairs, walking downstairs, sitting, standing, lying, using toilet, jogging, writing and typing, positioning the Smartphone on hand. We collected labeled tri-axial accelerometer and tri-axial gyroscope sensors data from both male and female subject while they had performed listed activities. We developed an android application to attain required sensors data implying frequency of 1 Hz. After that, we applied a Dense Neural Network a.k.a. DNN model to predict the activities from collected accelerometer and gyroscope sensors data. We also practiced Support Vector Machine, Decision Tree, K-Nearest Neighbor, Random Forest, Naïve Bayes and Logistic Regression along with DNN for operative study. Our main goal was to scrutinize a comparative study on both male and female subjects' data with statistical and deep classifiers. We also corroborated that, data amassed in lower frequency may perform good classification too. We achieved utmost 94.38% and 93.35% classification accuracy on the male and the female dataset respectively using DNN model.

Keywords—Human Activity Recognition; Accelerometer Sensor; Gyroscope Sensor; Smartphone Sensor; Dense Neural Network

I. INTRODUCTION

Human Activity Recognition a.k.a. HAR intends to recognize and identify the actions and goals of one or more individuals from a series of espials over a period of time-based on the person's actions and atmospherically situation [1]. The sensing of the activities is the fundamental step for establishing an activity recognition system. It plays a vital role in establishing intercommunication between persons and helps them to develop their interpersonal relations. Due to the availability of enough and important sensors in Smartphone, it simplifies a better user experience, enhanced information by providing user-friendly and exciting applications about the world around the Smartphone and provide robust and increased battery life. It can be considered as the best and most used communication device as more than 2.5 billion people are using Smartphone worldwide.

The sensors which are included in the Smartphone produce a different type of data in the variation of the movement of the Smartphone. And, amassed data by the Smartphone sensors on the basis of the movement of the Smartphone can be used in identifying the types of human physical movement. After identifying the physical movements, reports related to the health issues can be generated and then those reports can be utilized for the diagnosis of human activity related diseases in a timely basis.

Deep learning allows building complex concepts out of simpler concepts. Here input data is passed through a series of non-linearity or non-linear transformations before it becomes output. In contrast, modern machine learning algorithms are considered shallow because, the input can only pass a few levels manual identification of features in data and instead relies on whatever training process it has in order to discover the useful patterns in the input example. Known transformations in Multi-Layer Perceptron's a.k.a. MLP while back-propagation speed up learning methods. Nonlinear functions having the range from -1 to 1, centering all factors to zero mean in gradient-descent based optimizing and this leads to a significant speedup in learning. In this disquisition, gradient factor centering were done instead of the transform of nonlinearities makes the easier to generalize contexts. Second order optimization methods are useful to decrease the number of iterations to pruning but they are heavy in cost in the computation of high dimensional model with large matrices.

In our exploration, we have collected tri-axial accelerometer and tri-axial gyroscope sensors data from both male and female subjects, placing the Smartphone on their hand. We developed an android application to attain required sensors data implying frequency of 1 Hz. After the data collection phase, since we have used an android application, we had an intense fear to experience faulty data due to

hardware or software error. Thus, we eradicated null values, outliers, inconsistent instances, and standardization approaches. And, we also performed Principle Component Analysis a.k.a. PCA to select required features. Then we feed them to the DNN model along with other baseline models like Support Vector Machine a.k.a. SVM, Decision Tree a.k.a. DT, K-Nearest Neighbor a.k.a. KNN, Random Forest a.k.a. RF, Naïve Bayes a.k.a. NB and Logistic Regression a.k.a. LR to recognize the activities in consonance with walking, walking upstairs, walking downstairs, sitting, standing, lying, using toilet, jogging, writing and typing. We achieved utmost 94.38% and 93.35% classification accuracy on the male and the female dataset respectively using DNN model.

In the rest of this disquisition, a precise literature review is described in section II. We have incorporated activity recognition methods in section III, experimental evaluation in section IV and section V summarizes about our findings and future scopes.

II. Related Work

There exist many studies for recognizing simple, complex or combination of both human activities where an accelerometer or gyroscope sensor was either used alone or in a combination of the accelerometer with gyroscope sensor [2]. Besides, with these two sensors, other sensors such as a magnetometer, temperature sensor, proximity sensor and so on were also used in the research field of human activity recognition.

To briefly go over the history of human activity recognition system, many researchers [3, 4] determined physical activities using multiple wearable sensors placed on body parts like knee, waist, arms and ankles. They developed a classification model for classifying activities which are sitting, walking and standing. Again, wearable sensors like blood volume pulse sensor, galvanic skin response sensor, an electromyogram sensor and a respiration sensor were used for the identification of physiological signals, but these wearable sensors are quite expensive as well as, maintaining those sensors needs regular efforts. Moreover, the wearable sensors should be lightweight and capable of providing high performance [5]. Other than wearable and ambient sensor, some works were done using Smartphone sensors. Bayat, et al. [6] and R. Kwapisz, et al. [7] determined six activities using the accelerometer sensor of Smartphone in different works. Recently activity recognition using sensor-based data became a hot research topic for a wide range of applications. Several works have been done related to human activity recognition. In the past, most of the works were conducted using ambient sensors or sensors attached to the body. A system was created using a combination of twenty different sensors to identify activities like walking, standing, laying etc. [8]. Similarly, Maurer, et al. [9] used an e-Watch to recognize six activities in consonance with descending, running, sitting, standing, ascending and walking. Moreover, Tapia, et al. [10] conducted research on home-usable sensors only. Later in another research, five accelerometers were placed on different locations of 21 gymnasts' body Tapia, et al. [11]. Activities namely walking, climbing downstairs, sitting down, standing up were being recognized by Brezmes, Gorricho and Cotrina [12]. For sitting, lying down, standing, walking, stair climbing, running and cycling Mannini and Sabatini [13] used five bi-axial accelerometers staying at the different body position such as hip, wrist, arm, ankle and thigh.

Some other simple activities like walking, running, upstairs, downstairs, sit-ups, brushing teeth, vacuuming recognized by Ravi et. al. [14]. They made a comparison of base-level and meta-level classifiers and resolved that combining classifiers using Plurality Voting is best for recognizing simple activities. For recognizing activities like walking forward, walking left, walking right, upstairs, downstairs, run forward, jumping, sit on a chair, standing Mi Zhang [15] proposed a Bag-of-Features approach which builds activity models using histograms of primitive symbols. Ten participants with activities in consonance with biking, stairs up, driving, lying, running, sitting, standing and walking using accelerometer sensor data was indicated by S. Dernbach et. al. [16]. Allocation of the Smartphone for collecting sensor data was user defined and sampling frequency was set to 80 Hz. Using Multi-layer Perceptron, those activities were classified acquiring accuracy of 93%. Besides, these complex activities such as, making coffee, making tea, toileting, ironing, drinking, making a meal, applying makeup, shaving and so on are recognized by Tao [17] by building activity models that mine a set of Emerging Patterns from a sequential activity trace. Activities that are required for preparing work, going shopping, doing housework such as office work, commuting, lunch, dinner are identified by Tam Huynh et. al. [18] using topic model. A combination of simple and complex activities such as cooking, cleaning, medication, sweeping, washing hands, and watering plants were recognized by Stefan et. al. [16]. They used fixed time window length with an overlap of one half of the time window length.

III. Human Activity Recognition Methods

In this section, we described the data generalization process, activities we are intending to identify and feature selection approaches.

A. Data Collection

We used a Xiomi Redmi 4A Smartphone that includes tri-axial accelerometer sensor and tri-axial gyroscope sensor to collect the user data. Both male and female data subject placed the Smartphone on their hand position, tied with a band while performing enlisted ten activities. They performed each activity for a specific period of time. Our experimental datasets contain twenty thousand instances as well as sensors data for male and female subject respectively. The android application that controlled the data collection process has a user interface to interact with the data subject and ask for permission to use sensor data so that no privacy violation occurs. In addition, the android application allowed data subjects to start or stop data collection. It also allowed data subjects to control the data collection for specific activities. We collected sensor data in 1 Hz of frequency for all activities.

B. Activities to be Identified

Human activities are mainly divided into two categories, they are, impulsive and steady activities. In our research, we considered both impulsive and steady activities. We intended to classify walking, walking upstairs, walking downstairs, jogging, typing and writing as impulsive activities and standing, sitting, lying, using toilet activities as steady activities in respect to the motion type of hand. These

activities are regularly performed by common people on daily basis. It is clear from their categories that, all the patterns are distinctive either on the periodic structure or in magnitude. Impulsive activities are distinguishable in periodic nature of oscillation and steady activities are distinguishable in the magnitude of the sensors data. Here, sensors data of tri-axial accelerometer and tri-axial gyroscope plotted for jogging as an instance of impulsive and sitting as an instance of steady activity for both male and female subjects.

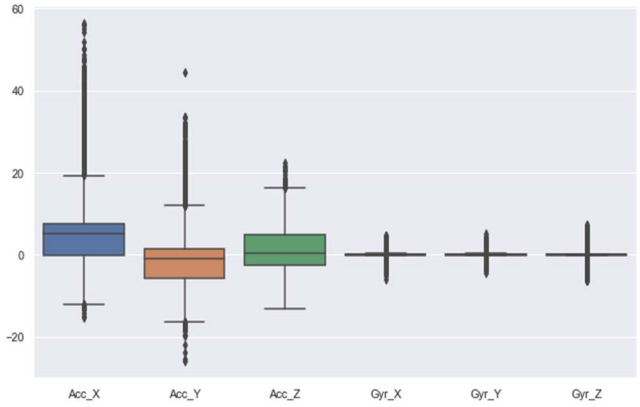

Fig 1: Frequency distribution of features of the male dataset in box-plot

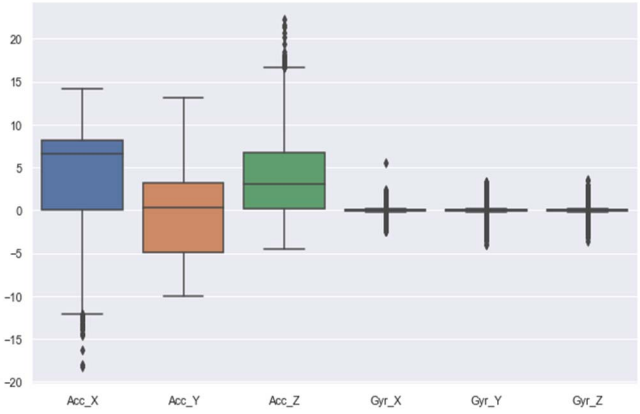

Fig 2: Frequency distribution of features of the female dataset in box-plot

C. *Pre-processing and Feature Selection*

In supervised learning, many candidate features are introduced to represent a better domain. But, many of these features are limited extent or utterly superfluous or irrelevant. Minimally sized feature subset drastically reduces the learning methods and running time of learning algorithm. As human activities are impulsive and non-impulsive as well as steady, we needed to select such features of sensors data that can differentiate between impulsive and steady activities. Since, we used an android application to amass data, we had intense fear to experience faulty data issue due to hardware or application error. Thus, we eradicated null values, outliers, and inconsistent instances. Since, tri-axial accelerometer and tri-axial gyroscope uses meter per square second and radian per second as unit respectively, thus we practiced the standardization approach in both dataset. And, Principle Component Analysis a.k.a. PCA is a technique to find features that are a subset of actual features to make a reasonable tradeoff to reduce or selection of features. Thus, we applied PCA technique on our dataset and we found out that, tri-axial accelerometer and tri-axial gyroscope sensors both have significant variations while performing orthogonal transformations, called rotations of the original features. We also found out that, all distributions put differently multivariate normal are sufficient enough to characterize the activities. Here is the plotting of variances of experimented features in a cumulative way after analyzing with PCA approach.

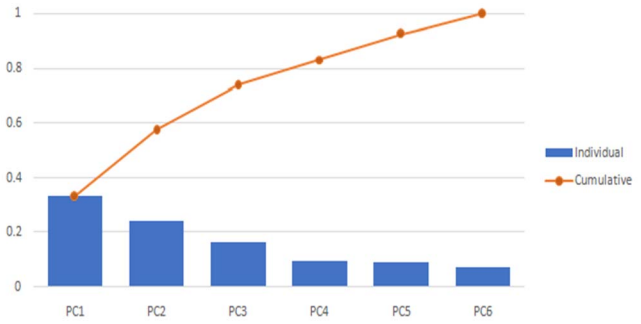

Fig 3: Individual and cumulative variance of principle components on male dataset

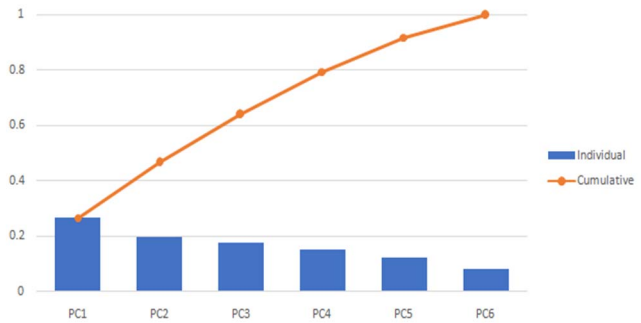

Fig 4: Individual and cumulative variance of principle components on female dataset

D. *Applied Machine Learning Algorithms*

To classify a data set, there are diverse machine learning algorithms. But, we applied Dense Neural Network a.k.a. DNN model and six base level classifiers naming Support Vector Machine a.k.a. SVM, Decision Tree a.k.a. DT, K-Nearest Neighbor a.k.a. KNN, Random Forest a.k.a. RF, Naïve Bayes a.k.a. NB and Logistic Regression a.k.a. LR.

Exercised DNN is composed of three or more layers (one input layer, one output layer and one or more hidden layers). Input layer receive the signal, output layer makes a prediction or decision about the input and the hidden layers are the true computational engine of the DNN. Formally, one-hidden-layer DNN is a function,

$$f: R^D \rightarrow R^D \quad (1)$$

Where, D is the size of input vector, X and L are the size of the output vector of f(x), such that, in matrix notation,

$$f(x) = G(b^{(2)} + W^{(2)} (S(b^{(1)} + W^{(1)}x))) \quad (2)$$

Where, bias vectors b(b(1),b(2)); weight matrices W(1), W(2) and activation functions G and S. The vector,

$$h(x) = \emptyset(x) = (s(b^{(1)} + W^{(1)}x))) \quad (3)$$

Constitutes the hidden layer $W^{(1)} \epsilon R^{D*D}$ is the weight matrix connecting the input vector to the hidden layer. Each column of $W^{(1)}$, i represents the weights from the input units to the i-th hidden unit. Typical choices for S includes hyperbolic tangent function and non-linear monotonic derivative of Rectified Linear Unit a.k.a. *ReLU* for multi-classification and logistic sigmoid function for binary classification respectively. These activation functions are mathemathically noted as,

$$tanh(z) = (e^{(z)} - e^{(z)}) / (e^{(z)} + e^{(z)}) \quad (4)$$

$$logit(z)= 1 / (1 + e^{-(z)}) \quad (5)$$

$$ReLU(z) = max(0, z) \quad (6)$$

All activations are scalar-to-scalar functions but their natural extension to vectors and tensors consists in applying them element-wise (e.g. separately on each element of the vector, yielding a same-size vector. The output vector is then obtained as,

$$O(x) = G(b^{(2)} + W^{(2)} h(x)) \quad (7)$$

Naïve Bayes classifier, structured on Bayes theorem, can be prescribed as a submissive but till now a robust data mining algorithm. The tentative feasibility i.e. feasibility of the manifestation of an instance given that, another instance has been taken place is illustrates by the Bayes theorem. Mathematical depiction of Bayes theorem pursue the below form:

$$P(X|Y) = P(Y|X)P(X) / P(Y) \quad (8)$$

Where, *P(X)* symbolize the preceding feasibility of manifestation of instance X, *P(Y)* denotes the preceding feasibility of manifestation of instance Y, *P(Y|X)* gives the succeeding feasibility regarding the manifestation of event Y given the instance X is true and *P(X|Y)* demonstrate the conditioned feasibility of instance X given Y is true. But in terms of categorization problem we can narrate Y as the data sample with unidentified class, X as the hypothesis of Y belongs to category C and *P (X|Y)* as the probability that for given data sample Y the hypothesis holds.

On the other hand, one of the most influential classifier named Random Forest, can be unfold as an ensemble learning mechanism that exaggerate the conjugation of decision tree. Initially a figure of decision trees are being proposed by Random Forest where, vindication nodes allude the predictor variables. Consecutively, the concluded effect of the performance are being affected by those achieved decision trees. In spite of the fact that, advancing of exalted dissonance may be boot up by generated sub-trees but less over-fitting can be accomplished with the collation of the learning rate. In our classifier structured, we chosen to create 100 decision trees for bringing out the finest outcome. In a nut shell Random Forest operation can be introduced as:

1. Dictatorialswatch are selected from a provided dataset.
2. Decision trees are initialized to conclude prediction outcomes by employing selected swatch.
3. A deciding vote is accomplished employing the predicted results. Reckoning the most vote finalization of predictions was accomplished.

Support Vector Machine a.k.a. SVM, another well-known classifier generates differentiating hyper-plane that simplifies classification regarding subjects. In terms of classification, for a conferred figure of categories, a proficient hyper-plane is assemble which collaborate in categorizing the imminent samples. To timbre the SVM model, selection of accurate kernels as well as regularization parameter and gamma is conspicuous. Here, the kernels are integrated to ascertain the similarity scope among perverse features and gamma value helps to timbre the SVM model effectively. In general, kernels literally embellish the simplification of non-linear categorization and since binary classification are basically introduced by SVM.

In our SVM model architecture, we exercised the “rbf” kernel and a gamma value of 0.01 for which we acquired the maximum performance outcome.

Besides those classifier, another extensively applied classification approach entitled as KNN, a learning algorithm which is non-parametric, uses a dataset with the data points divided into diverse groups with the objective of predicting the association of a new sample. As it is non-parametric, without fabricating any conjecture on the data allotment of given data, it delimits a model structure. Thus, it should be one of the first choices to classify when there is little or no prior knowledge about the allocated data. KNN specifies an integer k where k>0 for a new sample. When k=11, maximum accuracy can be achieve from our model structure. For normalization process we regenerated each attribute value by the following manner,

$$New_x = X_{mean} - Old_x \quad (9)$$

Where, Old_x is an old attribute value, X_{mean} is the average of old attribute values and New_x is the new attribute value. We did it to avoid the domination of a single feature. For the normalization value of the new instance we used the following formula,

$$Normalized\ X_i = |X_i - X_{mean}| / Standard\ Deviation \quad (10)$$

Where, X_i is a new sample. It approve us to render all features to fetch them in a new level to simplify comparison between them. For discrete value, the consuetude of discrete values are computed by measuring the dissimilarity among their frequencies. Finally, KNN uses the similarity measure between the training data sample and the new data sample for the prediction.

To train our networks, we used 80% instances of our datasets and 20% instances to test classification performance. We implemented DNN with machine learning framework scikit-learn APIs. In the classifier model, we used six hidden layers where the first, second and third hidden layers has the same number of perceptron numbers which is 500, for fourth hidden layer the number is 300, for fifth it is 200 and finally for sixth hidden layer the perceptron number is 100. In DNN, the more the hidden layers, the better is the accuracy, as a consequence by using six we achieved a good accuracy [19]. For activation function we used ‘*tanh*’ i.e. the hyperbolic tangent function. As solver we used ‘adam’ classifying method that refers to a stochastic gradient based optimizer. To control the step size in updating the weights we set the

learning rate at 0.0001 with maximum 2000 iterations to prune the model within global maxima.

IV. Evaluation of Experiments

We trained 80% of our total dataset using the proposed machine learning algorithm and tested the rest 20% for both datasets. Here, confusion matrices in heat-map, representing the performance of Dense Neural Network on both male and female dataset.

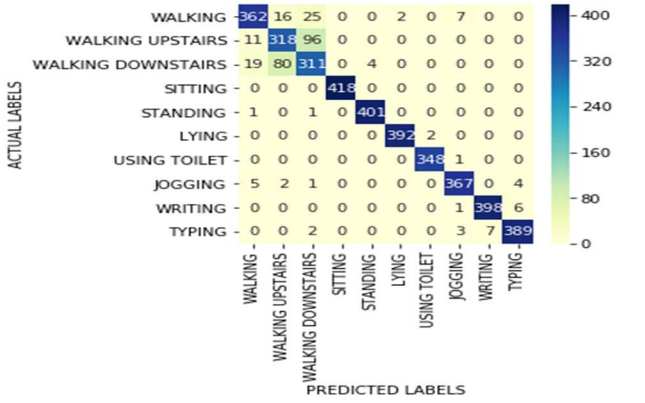

Fig 5: Performance of Dense Neural Network on male dataset

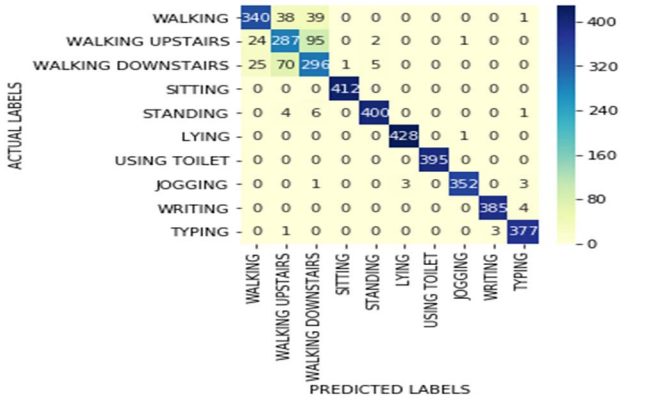

Fig 6: Performance of Dense Neural Network on female dataset

From the confusion matrix it is cleared that in case of male dataset for sitting, standing, lying and sitting in toilet all the instances were correctly classified. Great misclassification held for downstairs. Among 407 instances of walking downstairs 311 were correctly classified whereas 80 were misclassified as upstairs and 25 as walking, 1 as standing and 1 as sitting in toilet. Similarly, in case of jogging, writing and typing almost all instances has been correctly classified. From female dataset it is cleared that, all the instances of sitting and lying are correctly classified. For jogging among 418 instances only 1 instance were misclassified as typing. Greatest misclassification held for walking downstairs. Among 395 instances only 290 instances were correctly classified, and 39 were misclassified as walking, 70 as walking upstairs and 4 as standing. Though here we showed only the classification matrix for DNN as samples but we also obtained confusion matrix for other machine learning algorithm that is for SVM, DT, KNN, RF, NB and LR.

In case of SVM the accuracy we obtained for male dataset was 93.1% and for female dataset we obtained 92.25.For male dataset we found that from the 402 instances of standing, 399 were correctly classified where 2 were misclassified as downstairs and 1 as walking. The diagonal values of confusion matrix shows the number of instances that were correctly classified. On the other hand in case of female dataset from the 382 instances of standing 375 were correctly classified, 5 were misclassified as downstairs and 2 as jogging. For both dataset all instances of lying were correctly classified. For DT we obtained 89.52% accuracy for male dataset and 89.92% for female dataset. In KNN accuracy for male dataset was 93.42% and 92.52% for female dataset. We obtained highest accuracy for both male and female dataset in case of RF. It was 93.9% for male dataset and 92.85% for female dataset. From their confusion matrix it was cleared that, in male dataset for sitting all the instances were correctly classified. But for walking, upstairs and downstairs it shows greatest misclassification. And in female dataset all the instances of sitting and sitting in the toilet were correctly classified. We achieved lowest accuracy for LR. It was 77.42% for male dataset and for female dataset it was 76.97%. Biggest misclassifications were happened in recognizing walking, walking upstairs, walking downstairs and jogging for male dataset. And in case of female dataset misclassification found for walking, walking upstairs, walking downstairs and for standing. But for activities sitting in the toilet all instances were correctly classified. For NB accuracy obtained for male dataset was 85.32% and 85.45% for female dataset.

Table 1: Performance Estimation of Dense Neural Network and Base Level Classifiers

		Accuracy(%)	
		Male User Dataset	Female User Dataset
Dense Neural Network Model	DNN	**94.38**	**93.35**
Base Level Classifiers	SVM	93.1	92.25
	DT	89.52	89.92
	KNN	93.42	92.52

V. Conclusion and Future Work

In this paper, we determined, activity recognition task using two Smartphone sensors tri-axial accelerometer and tri-axial gyroscope. We predicted ten randomly performed human activities with higher accuracy for all practiced classification algorithms. We detected common activities as well as using toilet, writing and typing with Smartphone which are rare in previous works. We also showed comparison between two dataset which has not been done yet in previous studies. The data collection process was more reliable and the model developed showed better result than other Human Activity Recognition models. In future, we are planning to expand our work by predicting diseases from the predicted activities because pattern generated from daily physical activities have similarity in terms various diseases explanation. We would like increase both the number of sensors and human activities for further work. And, would also interested to extend our work using more splendid deep learning models whereas now we used only a Dense Neural Network model and some base level classifiers.

***Abstract*—Sensor data based Human Activity Recognition (HAR) has gained interest due to its application in practical field. With increasing number of approaches incorporating feature learning of sequential time-series sensor data, in particular the deep learning based ones has performed reasonably in uniform labeled data distribution scenario. However, most of these methods do not capture properly the temporal context of time-steps in sequential time-series data. Moreover, the situation becomes worse for imbalanced class distribution which is a usual case for HAR using body-worn sensor devices. To solve this issues, we have integrated hierarchical attention mechanism with recurrent units of neural network in order to obtain temporal context within the time-steps of data sequence. The introduced model in this paper has achieved better performance with respect to the well-defined evaluation metrics in both uniform and imbalanced class distribution than the existing state-of-the-art deep learning based model.**

***Index Terms*—Human Activity Recognition, Attention Mechanism, Gated Recurrent Unit**

I. Introduction

Human Activity Recognition(HAR) is a domain of research aimed at recognizing human actions and movements from a series of observations. The increasing public adoption of smart devices with sensors such as accelerometer and gyroscope has created the opportunity to organize considerable amount of sensor data for classification of human activity. The research activities focused on HAR incorporates the compilation of sensor readings into sequential time-series data and develops models for recognition of activities by analyzing the acquired sequential sensor readings. HAR poses a variety of promising application domain which includes physical activity annotation in the field of medical data analysis [1], personal assistant system [2], augmented and virtual reality [3] and many others.

In the past years, the state-of-the-art solutions to HAR mainly based on the traditional machine learning techniques. This techniques mainly depend on heuristic based hand-crafted feature engineering that rely on low level representations. As the traditional machine learning models use low level representations, it lacks the characteristics of generalization [4], [5]. High level abstraction along with low level representations are necessary for a likely solution to this generalization problem.

Deep learning based methods deal with both low and high level representations of data. Therefore, recently two variants of deep learning methods namely convolutional [6] and recurrent [7] neural network models are become dominant over traditional methods in terms of performance. For example, to identify HAR, convolutional neural network(CNN) is used in [8] and [9] and recurrent neural network(RNN) is used in [7] and [10].

Although deep learning based methods show promising performance, conventional sliding window based approach for CNN is unable to fully capture the temporal context of the sensor reading [11] which is required for better classification of activities. For sequence data, RNN performs better than CNN in most cases as it captures sequence information [12]. However, RNN faces long term dependency problems [13] when the sequence is long enough. Note that, the sequence information found in HAR data is usually long. So, it is necessary to capture the long term dependency information for better classification.

Gated Recurrent Unit (GRU) is a variant of RNN which incorporate long term dependency information [14]. It is expected that GRU will perform better in case of HAR data as it is able to capture temporal context of sensor data. It is noteworthy to mention here that, all temporal context are not equally important for classification, some are more important than others. Hence, it is necessary to give more attention to the important temporal context than others. Moreover, during the acquisition of HAR data, usually the training data found for different activities are not equal which causes class imbalance problem. The emphasis on important temporal context also helps to solve this problem.

To capture the nature of different continuous movements

and to extract the salient features, in this paper, we propose an attention mechanism based GRU model architecture. This architecture plays a crucial role in capturing context of the sensor reading and extracts the class imbalance tolerance characteristics. The main contributions of this paper are as follows:

- We propose to use a hierarchical temporal attention with GRU for capturing important temporal contexts.
- The hierarchical model propose to use here is parallelizable.
- The model is able to handle class imbalance problem.

The paper describes related work in section II where different approaches for recognition of human activity are discussed. Section III has been used for describing the proposed methodology. Section IV contains the results as well as interpretations of the outcome of the proposed method. Section V concludes the paper.

II. Related Work

The most referred work proposed in [15] use fast Fourier transform algorithm for feature extraction, useful in recognizing different activities, that produce satisfactory results with numerous sensors set on distinctive parts of the body in conjunction with various data mining algorithms. Different approaches like K-nearest neighbors [16], decision trees [17], multi-class support vector machine [18] are used to classify human activities. All of these approaches require the use of hand-crafted features and show poor results for classifying in similar type of activities like walking down and walking up.

In the modern age, deep learning has become prominent in the area of learning models that represent features from low-level to high-level abstraction used in [4], [5] which allow to extract features automatically without hand-crafted feature engineering. A common form of neural network called fully connected neural network (FCNN) with Principal Component Analysis based feature technique is used in [8] and [9] for HAR and sensor data. But FCNN is very expensive in terms of memory (weights) and computation (connections). It also has a great chance of overfitting problem as every node is connected with every node in every layer. To extract additional features a new technique called Shift-invariant sparse coding [9] was proposed and used in combination with FCNN and handcrafted features. Convolutional neural network (CNN or convnet) [19] with dropout [20] for reducing overfitting is a recent breakthrough for feature extraction. It is used by [21] in gesture recognition that give state-of-the-art result. A hierarchical model using convnets is proposed in [22]. To recognize human activity for unlabeled as well as labeled data, [23] used semi-supervised convnet model to learn discriminative hidden features. Where convnet learns to recognize features of an object and combine these features to recognize larger object. Recurrent Neural Networks (RNN) based appoach proposed in [7] to recognize human activities and abnormal behaviour, shows some promise but leaves room for improvements. When the sequence is long, RNN faces log term dependency problems. To solve this problem, a combination of convnet and long short term memory [10] is used in [24] that outperforms other models on the KTH dataset. Gated Recurrent Units [25] are a variant of RNN that also addresses long term dependency issues. Adam optimizer [26] is a popular choice for training such neural networks.

Attention mechanism, introduced for sequence to sequence tasks tasks such as neural machine translation [27], speech recognition [28] has also been used for classification tasks in the domain of natural language processing [29]. The context vector computed by attention helps the network to learn where to focus on the representation generated by the encoder part for generating output sequence at each time step instead of compressing entire sequence to a fixed vector at once. Simplified form of attention mechanism [30] has been proposed for feed forward network which captures some long term dependencies.

The approaches described so far for activity recognition fail to capture the temporal context of sensor reading at different time steps of activity data which is required for better accuracy and generalization. Another approach proposed by [31] uses attention mechanism on top of a complex DeepConvLSTM architecture for finding relevant temporal context for activity recognition. In this work attention score is generated by applying attention after convolutional and pooling layers in DeepConvLSTM. This score does not reflect the hierarchy of simple features detected from raw sensor data and complex features detected from hidden state outputs in case of RNN (or from deeper layers in CNN). For finding relevant features for activity recognition, feature selection approaches used in [32], [33] can be applied. However, In this work, we propose an attention mechanism with GRU which distills more complex features that would be helpful for better classification.

III. Proposed Method

The proposed method combines several building blocks for constructing the network. We use Gated Recurrent Units, two different types of attention mechanism which are described in the following sections.

A. Gated Recurrent Unit

GRUs are a variant of Recurrent Networks that have been shown to be able to capture long term dependencies in temporal data while not suffering from similar vanishing gradient problem as regular RNN and requiring fewer parameters than LSTM. Hidden state $h_{<t>}$ calculation is based on (3) with the input vector $X_{<t>}$ and previous hidden state $h_{<t-1>}$ going through update and reset gates in (1) and (2).

$$Z_{<t>} = \sigma(W_{zx} \cdot X_{<t>} + W_{zh} \cdot h_{<t-1>} + b_z) \quad (1)$$

$$\Gamma_t = \sigma(W_{\Gamma x} \cdot X_{<t>} + W_{\Gamma h} \cdot h_{<t-1>} + b_\Gamma) \quad (2)$$

$$\begin{aligned} h_{<t>} = (1 - Z_{<t>}) \odot h_{<t-1>} + \\ Z_{<t>} \odot \tanh(W_{hx} \cdot X_{<t>} + \\ W_{hh} \cdot (h_{<t-1>} \odot \Gamma_t) + b_h) \end{aligned} \quad (3)$$

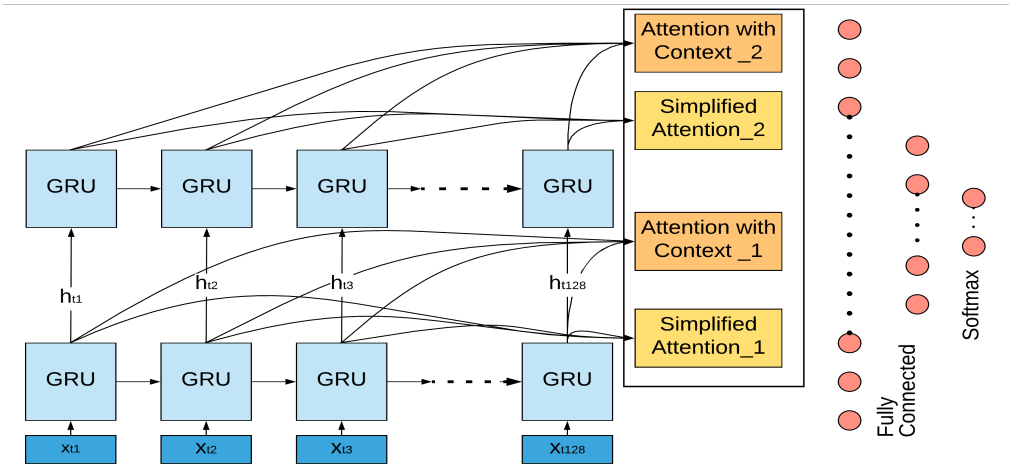

Fig. 1: Stacked 2 layer GRU model with simplified and context sensitive attention mechanism

Here, σ is used in (1) and (3) which refers to sigmoid function and $\odot$ in (3) represents element-wise multiplication.

B. Attention Mechanism for HAR

Context vector generated by attention allows a classification model to give varying levels of importance to the different temporal features generated by a recurrent network. Different variations of attention mechanisms such as simplified attention and hierarchical context based attention could be used for this type of tasks. These two types of attention could be used separately or a combination of their learned attention scores may be used. We take the latter approach.

1) Attention With Context: Because of susceptibility of sensor data to noise, context of a sensor value in relation to data on other time steps are helpful for creating a representation of data for classification. By using attention on both layers of stacked GRU, the model is able to exploit hierarchy of temporal features in the sensor data.

$$e_{<t_i>} = \tanh\left(W_{ac} \cdot h_{<t_i>} + b_{ac}\right) \tag{4}$$

$$\alpha_{<t_i>} = \frac{\exp(e^T_{<t_i>} \cdot e_s)}{\sum_t \exp(e_{<t_i>} e_s)} \tag{5}$$

$$c_{<i>} = \sum_t \alpha_{<t_i>} h_{<t_i>} \tag{6}$$

W_{ac} and b_{ac} in (4) are parameters to be learned. e_s in (5) allows the preservation of context information and is learned jointly when training the network. A summation of the relative weights of the time steps is generated as the context vector in (6).

2) Simplified Attention: Sensor data of human activities differ from natural language data in that words are context dependent in most cases where sensor data may not depend on the context. Simplified attention does not have to learn the e_s parameter.

$$e_{<t_i>} = \tanh\left(W_{as} \cdot h_{<t_i>} + b_{as}\right) \tag{7}$$

$$\alpha_{<t_i>} = \frac{\exp(e_{<t_i>})}{\sum_t \exp(e_{<t_i>})} \tag{8}$$

Context vector is obtained using (6) using the relative weight $\alpha_{<t_i>}$ obtained from (8)

C. Proposed Model Architecture

We propose a two layer stacked GRU architecture with attention applied to the hidden state outputs of each recurrent layer. The stacked layers help to learn more complex features from the sensor data. The attention scores from both layers are concatenated to create a hierarchy context vectors before feeding it to the densely connected layers. Both simplified and context-based attention scores are computed independently. Batch normalization is used before applying attention and after the concatenation of the the attention scores. There are three fully connected layers after attention module. The first two layers are used to learn respective weights for the different types of features obtained from the attention modules. Rectified Linear Unit (ReLU) is used for the activation of these layers. Dropout is also performed for regularization with probability d_1 and d_2. Dropout prevents a neural network from becoming heavily dependent on a specific weight of a single neuron by turning off a fraction of the neurons randomly during training. For classifying human activities, softmax activation is applied to the final layer. The model architecture is illustrated in Fig. 1. We train the model with learning rate α and decay factor λ.

Note that, a simpler model using a single GRU layer with same attention mechanism may also be used. Such a model requires fewer parameters to learn and resulting in less computational complexity. However, such simpler model may result in lower performance. In the proposed model architecture, sequential computation overhead may be reduced by computing the attention scores as well as the hidden states for the second GRU layer in parallel. In this case we can achieve better performance with much less time.

We use attention mechanism with GRU. Attention score may be calculated on derived features of CNN layers which may lead to the loss of context information. In comparison, using attention mechanism on the hidden states computed directly from sensor data facilitates better learning of the temporal contexts. In our proposed model, we use two types of hierarchy: firstly, hierarchy with two different types of attention (e.g. simplified and with context) and secondly, attentions from multiple layers of GRU. Using such a hierarchy of attention allows the incorporation of less complex features (low level information) with more complex features (high level representation of features) required for classification.

IV. Experiment Result and Description

A. Dataset Description

In this experiment, we use the benchmark HAR dataset [34] which provides time series information of six different activities(walking, walking_upstairs, walking_downstairs, sitting, standing and laying). Two types of sensor namely accelerometer and gyroscope are used to capture these information and randomly partitioned into 70% train and 30% test sets. Data has been preprocessed with noise-filters and sampled in fixed length sliding windows of 2.56 sec and 50% overlap which yields 128 readings per window. The training data is generated with a total of 7352 examples incorporating data of 21 randomly selected individuals. On the other hand, test set is composed of 2947 examples incorporating the remaining 9 individual subjects selected for this specific dataset.

B. Implementation Detail

During training, Adam optimizer is used with its default parameters (β_1=0.9 and β_2=0.999) for backpropagation. Moreover, the initial α is set to 0.001 which is presented in [35] with λ = 0.2 (decay based on validation loss). The dropout probability d_1 and d_2 are set to 0.25 and 0.1 respectively in the fully connected layers.

The standard accuracy metric defined in 9 is used to evaluate the methods used in this experiment.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \tag{9}$$

where, TP, TN, FP and FN are defined as True Positive, True Negative, False Positive and False Negative respectively.

To evaluate the performances of the methods in the class imbalance scenario, we first drop half of the training data and second drop two-third of the training data. In both cases, we keep unchanged test data (mentioned in the Dataset Description subsection). For measuring the performance of the methods in the class imbalance scenario, we use area under the curve (AUC) as an evaluating metric in this case.

We also performed five fold training (in each case, we consider 17 individuals information of all classes except the imbalanced class) and test (in each case, test data is fixed with 9 individuals as mentioned in the dataset description subsection) with 50 percent dropout of the training data of a specific class that is considered as an imbalanced class.

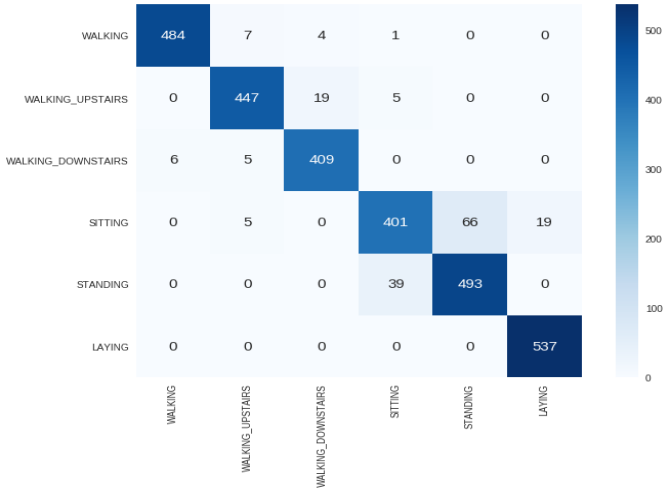

Fig. 2: Confusion Matrix when half of the training data for class 'Walking Downstairs' is dropped for stacked GRU model

C. Result and Discussion

In this experiment, we have compared our proposed model architectures with a state-of-the-art baseline CNN based method [6]. The column two of TABLE I presents the comparison according to the experimental setup described in the HAR dataset. It is observed from this table that in terms of accuracy, our proposed stacked GRU with attention performs better from both the proposed simplified model (with GRU + Attention) and the baseline CNN based method. Such an improvement is expected as we consider hierarchy in the attention model and two layer stacked GRU.

We have demonstrated the impact of class imbalance in TABLE I (Column 3-8) and TABLE II for different methods. In both cases (1/2 and 2/3 class drop), our stacked GRU with attention wins for all classes in terms of accuracy. Besides these, to test the generalization ability of the proposed method, we perform five fold training and test as mentioned in the implementation detail subsection. These results is demonstrated in TABLE III. In this case, we consider AUC as a performance metric as it performs better for imbalance dataset [36]. From this table, it is also observed that when imbalanced is injected, the proposed method wins for every classes individually which demonstrated the superiority of the proposed method.

Note that, the improvement of the proposed method with the baseline CNN model observed in the aforementioned tables is not that significant. The reason for such slight improvements can be explained by the simplicity of the dataset. In the dataset, the activities are separable by a large margin which is shown in Fig. 4. The figure is generated with dimension reduction using t-SNE [37]. So that when we create class imbalance,there is no significant drop in accuracies for both of the methods and the difference between these two methods in terms of accuracy also remains small. We believe, the improvement will be much larger for more challenging dataset.

We demonstrated the confusion matrix of the proposed method and baseline CNN in Fig. 2 and 3 respectively. The

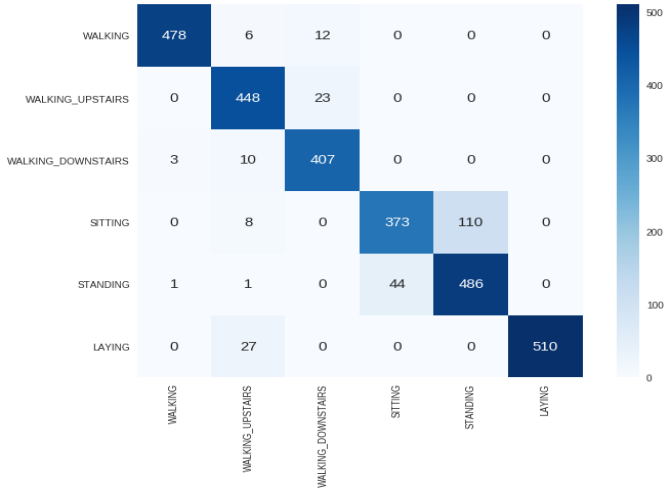

Fig. 3: Confusion Matrix when half of the training data for class 'Walking Downstairs' is dropped for CNN model

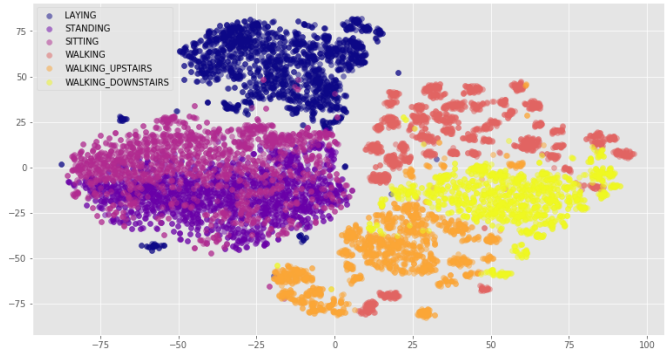

Fig. 4: Visualization of the separation of activities

confusion matrix indicates that misclassification occurs rarely and also within the vicinity of ground truth class even in imbalanced class scenario. However, from these two figures, it is observed that the proposed method has fewer misclasssification compare to the baseline CNN.

Based on the results in this experiment, it is evident that the proposed method is better in terms of accuracy and AUC metric. This method is able to produce such result by giving the attention to both simple and complex features which are learned from the proposed combination of two attention mechanisms.

V. Conclusion

The proposed method performs reasonably well for the recognition of human activity while not being sensitive to class imbalance in the training data as it learns temporal features using attention mechanism. More parrallelizable models could be developed in the future by constructing embedding from the temporal data. In this paper, we intend to show the effectiveness of the proposed mechanism using a benchmark HAR dataset. We believe the proposed method will also perform better for more complex datasets, collected from heterogeneous devices that have more varied class distribution in terms of activity duration and feature complexity which we will address in future.

Abstract**—** In the case of modern diagnosis technology, WCE (Wireless Capsule Endoscopy) is one of the most efficient and effective technologies for the diagnosis of Gastrointestinal tract noninvasively. Bleeding in the GI tract is one of them. Since the duration of the WCE video is so long, it contains a large number of images. Consequently, it makes a huge burden for the physicians to recognize affected portion in the real required time and it is the main obstacle for using the WCE in the wider application. For releasing the extra burden of the clinicians, we have proposed a novel automatic computer-aided system for detecting bleeding in the GI tract. In our proposed method, we have applied some special preprocessing for obtaining the required informative portions of blood. A noble Weighted k-Nearest-Neighbor (WKNN) classifier has applied for separating distinct object with some statistical features in HSV color space. We have successfully achieved accuracy 98.8%, sensitivity 99%, specificity 99%, precision 95%, negative predicted value 99% and F1 score 97% after extensive experiment which will outperform some of the existing researches. More importantly, its computational time is very compared to others.

Keywords— Digestive tract, HSV, WKNN, Wireless Capsule Endoscopy, QSVM, Bleeding Detection

I. INTRODUCTION

Gastrointestinal tract diseases such as small intestine, large intestine, stomach etc. have become the largest problem in our modern era of life. A lot of peoples around the word are suffering seriously from this type of diseases including Bangladesh. In an observation, it has observed that approximately 27.8% peoples in Bangladesh are suffering from and die for bowel taint [1]. In another observation it is observed that 1.6 million peoples of American are suffering from and die for IBD (inflammatory bowel disease). This IBD has become epidemic since 2011. Diagnosis for the IBD has increased up to 70,000. Approximately 80,000 babies are suffered from CD (Crohn's disease) or UC (ulcerative colitis) [2] . The IBD has become the most common concern in the whole world [3]. So, the process of curing GI tact problem should be developed in a rapid way. The diagnosis and therapy of GI tact diseases are devolved with revolution due to the invention of fiber optic endoscopy to visualize lower and upper GI tract. But by using this procedure only small bowel, distal ileum and proximal duodenum can be visualized. For improving the endoscopy process, there are a lot of procedure are practiced like, endoscopy biopsies, X-ray, CT scan, ultrasound, endoscopy etc. but they failed to improve the process and give relief to the patients. The revolution is created in the arena of endoscopy process when CE is discovered in the year of 2000 by Given Imaging Company and employed in 2001 [4]. This procedure not only makes visible the small intestine of GI tract but also provides a new technology in which the images from GI tract are captured by a swallowed capsule without pain. In accordance with the acceptability, safety and value this technology has developed and this is certified by US FDA (Food and Drug Administration) [5]. After that CE is considered as the best possible procedure to investigate the whole small bowel for visualizing in a discretion way [6]. The use of CE is increasing day by day for visualizing the complete small vowel in a discretion way

In order to help the clinicians in diagnosis GI diseases, the process of automatic bleeding recognition from the WCE images plays a significant role [7]. Wireless transmitter, color camera, Light, image sensor and battery are the major components of WCE. To complete the whole GI tract, it takes 8 hours and captures approximately 57,000 images including 2 frames for every second. These captured images are sent to a computer with the help of a transmitter which is operated by radio-frequency [8]. Then the clinicians check out the diagnosis images for finding bleeding portion or some other disease indications which takes almost two hours to perform completely [9]. Very often it is too difficult for the clinicians to detect the symptom of the disease due to small size or unequal distribution of the objects in the image frames and also the oversight problem of the physicians. These problems courage the researchers to propose

a method for automatic bleeding detection as computer aided system[10].

A. Related Work

To release the burden of the clinicians, different types of bleeding detection technology have already employed from WCE. But they provide unsatisfactory result in specificity and sensitivity like SBI (Suspected blood indicator) technique [11], [12]. First of all a software was designed for detecting bleeding region whose sensitivity and specificity were only 21.5% and 41.8% [13]. According to [14] bleeding and ulcer has detected from of capsule endoscopy images which signifies chromaticity moment using HSI (Hue-Saturation-Intensity) color space and they got 91.50% accuracy, 94.56% specificity and 79.25 % sensitivity. After that a lot of research has been done by the researchers to develop in this arena. In [10] Probabilistic Neural Network (PNN) is proposed for bleeding detection and PNN classifier was developed for recognizing bleeding region. The result in accordance with specificity and sensitivity was 85.6% and 93.1% respectfully. In [14] they developed cluster-based sampling and create a method to study about large and disequilibrium data set in order to detecting bleeding image from CE.As multiple training data set was created in a random fashion, it reduced the loss of information. They also used SVM classifier for recognizing bleeding region which provided with better sensitivity and higher specificity. In [15] they developed a process which was able to reduce the complexity for computation by using super pixel segmentation process and also maintained higher degree of accuracy, sensitivity and specificity. The extracted the feature in the RGB space from the super pixel using red ratio and imposed into the SVM classifier. They also emphasized on the reduction of edge pixels. In [16] they have used different type of color feature like for CCV, RGB and HSV and got the accuracy and sensitivity in the purpose of bleeding detection 93.64% and 92.86% respectfully for CCV features. In [17] they have used the statistical features in the case of RGB color space for single order histogram provability. For distinguishing the bleeding image they have used neural network pattern and got 93% accuracy, 90% specificity and 96 % sensitivity. Again in [18] they have used frequency spectrum in the consideration of characteristics pattern. They have developed a technique which works on NGLCM (Normalized Gray Level Co-occurrence Matrix). They got a tremendous result in their proposed method. In [19] they have introduced two fold system. First of all they have taken color information to apply K-means clustering to obtain cluster Centre and observe the histogram. Then they have applied SVM classifier to differentiate the bleeding image and they got 95.75% accuracy in the case of YCbCr color space. In [20] they have emphasized on time consuming purpose. They have proposed feature extraction of holistic based on pixel. They have also introduced changeable color domain instead of using RGB color space directly. Statistical feature on the basis of lower and higher are used for the composite color space. Then they have applied SVM classifier to differentiate the bleeding image and they got satisfactory result.

This paper provides with a unique proposed method for bleeding recognition from WCE images in HSV color space. At first the WCE images are acquired by converting the video footage of WCE into specified format of images. In order to highlight the informative portion in the images, some prepressing is applied and then RGB color images are converted into HSV color images. After that we have extracted some statistical features and employed the data based into unique WKNN classifier. This unique proposed method is applied publicly obtainable wireless capsule endoscopy data base for testing.

II. OUR PROPOSED METHOD

Before We have used a unique method in order to detect the existence of blood in WCE images which are obtained from the WCE video footage. In this work we have applied some preprocessing steps for removing the unusual portion of images and highlighting the abnormal portion which is bleeding on this circumstance. The method that we have used is easy to calculate, time saving and give more accurate result of performance parameters. The layout of our proposed method is shown in Fig. 1.

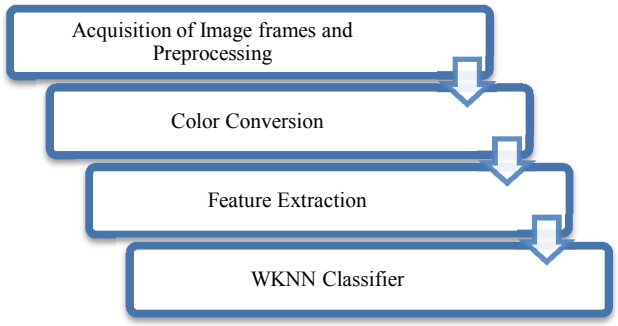

Fig. 1. Layout of our Proposed Method

A. Acquisition of Image Frame and Preprocessing

As discussed in the previous article that WCE is process of capturing the inner portion of our body but is in the video mode. So, in the initial stage of our work, we have to gather a strong database of images folder. This can be done by converting the video footage that obtained from WCE into image frame depending on the frame rate specified by the CE. This is done such that we can take necessary steps to perform any types of processing on the images, such as, preprocessing, segmentation, feature extraction classification and so on. On our work we have used PillCam®SB as CE whose frame rate is 2 and longevity is 8 hours which is sufficient to provide a enrich database for analyzing [21]. Among all of the we have used only 2393 images from the CE video to analysis which are available in [22]. After acquiring the image frames, we have to remove the black portions from the frames which don not contain any information. Firstly, for removing the black portion we took 67% of the image and cut out the remaining blackish portions from the frame which is regarded as preprocessing of the images.

B. Color Space Transform

HSV color model is associated with the three values of hue, saturation and value. HSV color model characterizes by the following three thinks [23].

- Color as hue
- On the basis of shade as saturation
- Last one is the brightness values

The ‘single hex cone model’ of color space is showing by the following Fig. 2 which describes the visualization of H, S and V parameters.

From the Fig. 2, the exterior side of the upper portion of the cone is referred to the original color and the angle of the circle is described by the H parameter. At the point on the axis of cone the value of s is 0 and it goes away from the axis if it increases the value of s. the color at the middle point of the circle is white. The value of V is like to the binary digit and 0 for black and 1 for white and goes from bottom to the center point of the circle [24].

Different statistical features of bleeding images are calculated by these corresponding values of three channel of HSV color space.

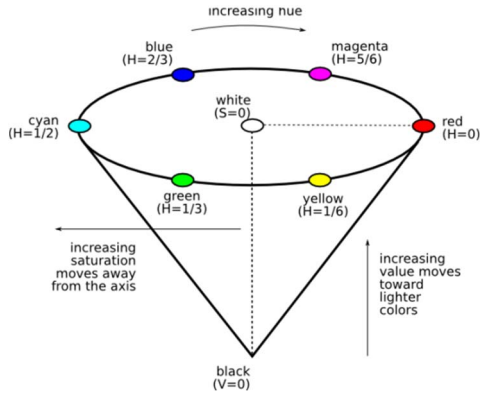

Fig. 2. Single Hex cone Model of Color Space (www.infohost.nmt.edu).

C. Bleeding Feature Selection

Feature extraction is the process of dimensional retrenchment which will represent the specified the information of a particular portion of image efficiently in a close-fitting feature vector. Over all, this vector contains some specified numerical values regarding the particular information of a determined sample. In order to extract features and calculations from the segmented image, we have used local standard deviation and mean of corresponding features of saturation, hue and value of the image as it provides with efficient results. These characterized features are applicable for the HSV color space since HSV color space is illustrated by saturation, hue and value. For that reason, we have converted the extracted image into the HSV color space and create the required feature victor. The values of hue, saturation and value of the HSV color image can be obtained by the following equations from the corresponding pixels values of three particular channel of RGB color space [25]. However, RGB is a color model which is described by three color channel such as red, green and blue. Simply RGB color space can be elaborated by every imaginable color which is formed from the above three channels. From the above notation every image has an intensity range of 0~255 of RGB elements.

$$H = arccos \frac{\frac{1}{2}[(R-G)+(R-B)]}{[(R-G)^2(R-B)(G-B)]^{\frac{1}{2}}} \quad (1)$$

$$S = \frac{\max(R,G,B) - \min(\mathrm{R},\mathrm{G},\mathrm{B})}{\max(R,G,B)} \quad (2)$$

$$V = \max(R,G,B) \quad (3)$$

For the purpose of classification, separate mean and local standard deviation is calculated from the specified values of hue, saturation and value. That's why we got a feature vector of total six specified feature. Sequentially, this vector is employed to the specified classifier in order to separate the bleeding information from the non-bleeding information.

D. WKNN Classifier

The Weighted K-Nearest Neighbor is the extended version of KNN and it is the observation of training data which is close enough to the new surveillance (b, a) and have the higher rate of weight which is apart from (b, a). Apart from the KNN the impact of the k is always analogous for all the neighbors though it may widely vary for the individual case. In order to fulfill this purpose, the distance has to transform into analogous measure which is referred to weights.

After this analogous measurement, each of latest point (b, a) will be categorized with the highest weighted added value as fellow,

$$\text{Max}_{\,m}\left(\sum_{i=1}^{k} k\left(D\left(a,a_{(i)}\right)\right) I\left(b_{(i)} = m\right)\right) \quad (4)$$

$$T = \{(a_i, b_i), i = 1, \ldots, n_M\} \quad (5)$$

Let equation (5) be the training data of a_i observation where a is the new surveillance and b have to be forecasted.

According to the function of distance $d\left(a, a_{(1)}\right)$, the value of k+1 nearest neighbor has to determine which is used to normalized the smallest k distance by the following equation (6)

$$D_{(i)} = D\left(a, a_{(i)}\right) = \frac{d\left(a,a_{(i)}\right)}{d\left(a,a_{(k+1)}\right)} \quad (6)$$

The normalized distance D(i) is transformed into weighted with kernel function as fellow

$$W_{(i)} = D(i) \quad (7)$$

Then the ultimate prediction will be

$$\hat{b} = \max_{m}\left(\sum_{i=1}^{k} w_{(i)} I\left(b_{(i)} = m\right)\right) \quad (8)$$

The main purpose of this method is to capture the degree of independency worst selection of k which results in a giant blunder classification error. Implicitly the quantity of neighbors is secluded in the weights. The value of k is adapted spontaneously if k is high enough. Neighbors with higher weight will influence the neighbors of lower weight even they have higher combination of neighbors [26].

The classification has been implemented having 10-fold validation techniques to split the samples into training and testing sets. After applying quadratic weighted k nearest neighbor classifier, we are able to separate the bleeding and non-bleeding images.

III. Result and Discussion

In the case of diagnosis like detecting bleeding or non-bleeding, the perfection of the work depends upon some major attributes. There are four possible events may be occurred at the time recognizing bleeding and non- bleeding images.

TABLE I
Extension of possible occurrence during classifying

Possible Occurrence	Extension
True bleeding detection (TP)	Detect the actual bleeding images

True non-bleeding detection (TN)	Detect the actual non-bleeding images
False bleeding detection (FP)	Detect as non-bleeding though it were bleeding
False non-bleeding detection (FN)	Detect as bleeding though it were non-bleeding

Accuracy is not the only reliable perimeter to justify the performance of work. Some other parameters like sensitivity, specificity, precision; F1score, negative predicted value etc. are the most reliable parameters to justify the performance of the work.

Sensitivity: Sensitivity detects positive disease. So, it describes the quantity or the probability of detecting the actual object what is actually needed to predict.

$$\text{Sensitivity}= \frac{Quantity\ of\ actula\ successful\ positive\ prediction}{Number\ of\ actula\ positives} \quad (9)$$

Sensitivity is the ratio of quantity of actual successful positive prediction to the number of actual positive [27].

Specificity: Specificity detects actually no disease. So, it describes the quantity or the probability of detecting the actual negative object. In short, it predicts negative when it actually negative [28].

$$\text{Specificity} = \frac{Quantity\ of\ actula\ negative\ prediction}{Number\ of\ actula\ negatives} \quad (10)$$

Specificity is the ratio of quantity of actual negative prediction to the quantity of actual negative [27].

Accuracy: Accuracy describes the measurement result of correct diagnosis test which finds out and shut out the provided condition. It can be calculated from sensitivity and specificity which is in the previous sections.

$$\text{Accuracy} = \frac{Quantity\ of\ actula\ prediction}{Total\ sample\ data} \quad (11)$$

Accuracy is the ratio of quantity of actual prediction to the quantity of total sample data [27].

Precision: precision can be defined as positive predicted value

$$Precision = \frac{Quantity\ of\ actula\ successful\ positive\ prediction}{true\ positive + false\ negative} \quad (12)$$

F1 score: In binary classification F1 refers to the test of accuracy and can be express by the following equation

$$F1\ score = 2 \times \frac{PPV \times TPR}{PPV + TPR} \quad (13)$$

Negative Predicted Value: NPV is the provability to describe the negative screening examination which truly does not contain positive objects and can be expressed by the following equation.

$$NPV = \frac{TN}{TN + FN} \quad (14)$$

As discussed earlier in our proposed method, we have used HSV color space, mean and local standard deviation of the corresponding channels or feature vector, unique WKNN classifier and the performance of the work is justified by sensitivity, specificity, precision, F1score, negative predicted value.

Table II
Performance correlation between different Characteristics features

Characteristics features	Accuracy (%)	Sensitivity (%)	Specificity (%)	Precision (%)	NPV (%)	F1 Score (%)
$\bar{V}, \sigma H\ and\ \sigma V$	92.6	86	94	74	97	20.4
$\sigma H, \sigma S\ and\ \sigma V$	93.2	86	95	76	97	36.4
$\bar{H}, \bar{S}, \bar{V}\ and\ \sigma H$	97.2	95	98	89	99	60.7
$\bar{H}, \bar{S}, \bar{V}\ and\ \sigma S$	96.8	92	98	91	98	29.3
$\bar{H}, \bar{S}, \bar{V}\ and\ \sigma V$	96.5	92	98	90	98	58.9
$\bar{S}, \bar{V}, \sigma H\ and\ \sigma S$	97.8	96	98	92	99	76.4
$\bar{S}, \bar{V}, \sigma H\ and\ \sigma V$	97.7	97	98	91	99	63.6
$\bar{V}, \sigma H, \sigma S\ and\ \sigma V$	86.5	94	96	81	99	47.2
$\bar{H}, \bar{S}, \bar{V}, \sigma H\ and\ \sigma S$	98.4	97	99	94	99	76.9
$\bar{H}, \bar{S}, \bar{V}, \sigma H\ and\ \sigma V$	98.6	99	98	93	99	70.7
$\bar{S}, \bar{V}, \sigma H, \sigma S\ and\ \sigma V$	98.5	99	98	93	99	69.2
$\boldsymbol{\bar{H}, \bar{S}, \bar{V}, \sigma H, \sigma S\ and\ \sigma V}$	**98.8**	**99**	**99**	**95**	**99**	**97**

Where, Mean Hue=$\bar{H}$, Mean Saturation= $\bar{S}$, Mean Value= $\bar{V}$, Standard deviation Hue=σH, Standard deviation Saturation=σS and Standard deviation Value= σV (We have observed many combinations of statistical features. However, we have indicated some selective combinations.)

In this case we have used 10-fold validation. The Table 2 shows the performance correlation between different combinations of specified features with performance parameters. It can be easily finalized that we got the best result of accuracy 98.8%, sensitivity 99%, specificity 99%, precision 95%, negative predicted value 99% and F1 score 97% by using mean of Hue, Saturation, value and local standard deviation of Hue, Saturation, and value combination than the other combinations. The Table II Shows the performance correlation between four color spaces by using the same classifier and provides the evidence that HSV color space is superior among all the color space mentioned in the Table II. The six performance parameters accuracy, sensitivity, specificity, precision, negative predicted value and F1score are higher in HSV color model than the others. Again, the Table III shows the performance correlation between different classifier that I have used to detect bleeding and non- bleeding images. It also gives the clarification that the WKNN classifier gives the better result among all the classifier mentioned in the Table IV like KNNN (K- nearest Neighbor) is the most commencement and nonparametric procedure in which a new surveillances settled toward the class of surveillance taking from the specified training set closest to the new surveillance for classification, QDA (Quadratic Discriminant Analysis) distributed the calculated value from the each class and without anticipating covariance of individual class is indistinguishable and Quadratic Support Vector Machine (QSVM) is a popular machine learning device that is considerd as a nonparametric scheme because of using kernel function.

Table III
Performance correlation between different color models

Color models	Accuracy (%)	Sensitivity (%)	Specificity (%)	Precision (%)	FPV (%)	F1 Score (%)
HSV	**98.8**	**99**	**99**	**95**	**99**	**97**
RGB	95.6	90	97	87	98	83
L*a*b*	98.4	97	99	94	99	73.7
YcbCr	98.2	97	98	93	99	84.35

Table IV
Performance correlation between different classifiers

Different classifiers	Accuracy (%)	Sensitivity (%)	Specificity (%)	Precision (%)	FPV (%)	F1 Score (%)
Fine KNN	98.5	95	99	95	99	80.6
QDA	96.5	91	98	94	98	75.8
QSVM	98.5	99	98	93	99	85.3
WKNN	**98.8**	**99**	**99**	**95**	**99**	**97**

In our research work, we have used some distinct classifier with validation process and modified the result by varying different perimeters. Just mentioned earlier, we have accuracy 98.8%, sensitivity 99%, specificity 99%, precision 95%, negative predicted value 99% and F1 score 97%by using 10-fold validation process with WKNN classifier. Though tremendous works have been done on bleeding detection, our work is unique and also improves in the arena of particular field. Comparison between the proposed method and the existing methods are shown in the following Table V and Table VI.

Table V
Performance correlation between different existing methods

Methods	Accuracy	Sensitivity	Specificity
CCV Feature [17]	92.86	93.64	-
Uniform LBP [9]	91.5	79.25	94.56
Binary feature vector	91	93.12	88.39
Red ratio in RGB space	94.8	97.02	93.56
Two fold System [20]	95.75	92	96.5
Different stricture of CNN [32]	97.18	96.94	97.18
Proposed Method	**98.8**	**99**	**99**

Table VI
Comparison between unique Performance parameters of existing methods

Methods	Precision	F1 Sore
Fu et al. [29]	86.17	83.51
Yuan et al. [30]	88.17	84.97
Jia et al.[31]	92.55	89.69
Jia et al.[32]	94.79	92.85
Proposed Method	95	97

From the above Table V and Table VI it is clearly shown that our proposed method is a developed version in the arena of bleeding detection in all terms of performance parameters among the existing work. In [33], they have used 2300 WCE images for analyzing the bleeding detection. Moreover, we have used 2393 images from the CE video to analysis which are available in [22] and give the strong evidence about the efficiency of our proposed method.

IV. CONCLUSION

This paper provides us with a unique proposed method for bleeding recognition from WCE images. This experiment exhibits that top most classification accomplishment is obtained with WKNN classifier with 10-fold validation technique, some essentials preprocessing and unique feature vector in HSV color space. The proposed method is analyzed for 2393 WCE images. The proposed features obtained the result accuracy 98.8%, sensitivity 99%, specificity 99%, precision 95%, negative predicted value 99% and F1 score 97%. It is examined that this statistical output of the proposed method is more efficient in term of accuracy, sensitivity and specificity than the indicated three comparable methods and capable to reduce the burden of the clinicians.

***Abstract*—** Among the syndrome of many dangerous diseases in the human digestive tract ulcer is one of the most common. Diagnosis of small intestine ulcers cannot be detected by using other procedures of endoscopy. For visualizing these ulcers, wireless capsule endoscopy (WCE) is excessively being used. In WCE system a huge amount of images are achieved which is very much difficult and time erosive for physicians to check manually. So, for helping the physicians it is very much needed to provide an automated computer-aided system. In this paper, an automated computer-aided diagnosis system is proposed for detecting ulcer from WCE images achieved from the capsule endoscopy video footage. In the first stage, we convert the source image into LAB color spaces for taking features. Then quadratic support vector machine (Q-SVM) classifier has been applied for separating the ulcer and non-ulcer images. Our achieved experiment results 90.39% accuracy and 99.00% sensitivity, validating the effectiveness of the proposed method. Therefore, results of the advanced methodology are given and statistical comparisons are also given related to the other works.

Keywords— Digestive tract, LAB, QSVM, Video footage, Wireless capsule endoscopy

I. INTRODUCTION

The Ulcer is a usual wound of the gastrointestinal (GI) tract. Throughout the world, about 10% of people are affected by this [1]. It is a lesion of the chronic inflammatory type which took place at internal mucous membranes. Ulcer especially digestive tract ulcer is caused by Helicobacter pylori bacteria and non-steroidal anti-inflammatory drugs (NSAIDs). The Ulcer is not fatal but it is the sign of some serious diseases especially Crohn's disease, ulcerative colitis, etc. [2]. In the early days, for ulcer detection in the GI tract, the conventional endoscopic system was used which was very much pain and discomfort because of its flexible tube, light, and camera, etc. After the invention of the transistors, it is possible to design swallowable electronic capsules for imaging the gastrointestinal tract. In 2001 Iddan first initiated video capsule endoscope called a mouth to anus (M2A) for the inspection of the small bowel. Due to its noninvasive property has numerous advantages over conventional endoscopy. Also, it is a painless technique and ability to do his daily activities [3]. A capsule endoscopy device consists of an optic dome, lens, LEDs, a CMOS camera, ASIC circuit, an antenna and a battery for power supply. After swallowing the capsule, it passes through the GI tract and captures images and transmit to a small portable recorder for storage via antenna. The images frame rate is 2 per second, approximately 50000 images were obtained within 8 hours of recording time of WCE system [4]. Signal strength is used to calculate the position of the capsule in the body. So, using this technique physician are able to identify the accurate position of ulcer in the GI tract [3].

(www.mayoclinic.org)

Fig. 1. Capsule endoscopy and sample WCE image

WCE images contain special properties of different diseases like Crohn's disease, ulcerative colitis, etc. Normally ulcer portion contains high-intensity value compared with its nearby area which seems as pinkish or white pinkish color that can be differentiated easily from non-ulcer portion [5].

A. Related Work

Many researchers devoted their efforts to make ulcer detection system fully automated. For this regard Francis *et al.* provide software for identification bleeding region in capsule endoscopy images which sensitivity and specificity is 21.50% and 41.80% respectively [6]. Then MPEG-7 visual descriptor was designed by Coimbra *et al.* for detecting the diseases such as bleeding, ulcer, and polyp [7]. Li *et al.* [8] provide a technique converting discrete curvelet transform (DCT) and local binary pattern (LBP) for feature extraction, which separates the ulcer and non-ulcer images. Karagyris *et al.* [9] proposed a technique in the HSV color space with Log Gabor filter to segment the Hue component of the WCE images to obtain the ulcer portion. Then for classifying the ulcer images from the non-ulcer, the RGB values and texture information are extracted. Yu *et al.* [10] proposed a method for ulcer detection using bag of word with spatial pyramid kernel and feature fusion techniques. Eid *et al.* [11]

introduced a method called DCT-LAC where curvelet-based lacunarity textures are used for feature extraction by calculating the lacunarity index of the WCE images. Ghosh *et al.* [5] proposed a technique for ulcer detection using histogram bin frequency of RGB color space. Another scheme proposed by Kundu *et al.* [12] using Y plane histogram of WCE images for ulcer diagnosis. In our proposed scheme features has been taken from L*a*b* color domain and classification is done by quadratic SVM classifier for separating ulcer and non-ulcer images.

II. OUR PROPOSED METHOD

The proposed scheme for ulcer identification is easy and proves low computational cost. Where some task is applied as pre-processing which is the preparation for implementing the scheme. Then the CE images are converted to L*a*b* color spaces from where features are taken for classification. In this technique, quadratic support vector machine (Q-SVM) classifier is applied for classification.

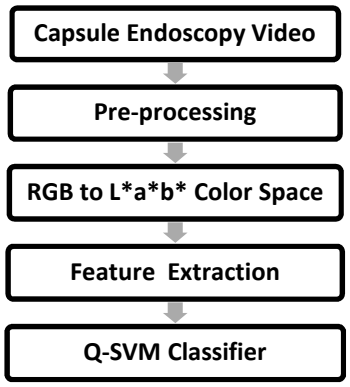

Fig. 2. Flow diagram of the proposed scheme

A. Pre-processing

The first task in our proposed scheme is the conversion of video into images. Basically, on these images, this proposed scheme is applied. The acquiring images converted from the video of capsule endoscopy will be in according to the frame rate of the capsule specification. We have used video of PillCam®SB whose frame rate is two per second with eight-hour battery life. Hence, approximately 57,600 images are achieved from the whole process. Among these huge amounts of images, we have used 110 ulcer and 135 non-ulcer images for this proposed scheme which are available in [13]. On these acquiring images, some algorithm is applied for removing the peripheral black portion of each image frame.

B. Color Space Transform

The images that we take as our database is images of RGB color image. An RGB (Red, Green, Blue) image is an image containing three-pixel values of red, green, and blue color.In RGB color space an image can be represented by the following function,

$$I_{rgb} = \left(P_R, P_G, P_B\right) \tag{1}$$

Where, $P_R(x,y)$represents pixel values (x, y) of red channel, $P_G(x,y)$represents pixel values of green channel and $P_B(x,y)$represents pixel values of blue channel [14]. The RGB color images can be transformed into L*a*b* using the following equations [15].

$$\begin{bmatrix} X \\ Y \\ Z \end{bmatrix} = [M] \begin{bmatrix} r \\ g \\ b \end{bmatrix}$$

Here, [M] The transformation matrix.

$$x_r = \frac{X}{X_r} \qquad y_r = \frac{Y}{Y_r} \qquad z_r = \frac{Z}{Z_r}$$

$$f_x = \begin{cases} \sqrt[3]{x_r}, \text{if } x_r \rangle \in \\ \dfrac{kx_r + 16}{116}, \text{ otherwise} \end{cases}$$

$$f_y = \begin{cases} \sqrt[3]{y_r}, \text{if } y_r \rangle \in \\ \dfrac{ky_r + 16}{116}, \text{ otherwise} \end{cases}$$

$$f_z = \begin{cases} \sqrt[3]{z_r}, \text{ if } z_r \rangle \in \\ \dfrac{kz_r + 16}{116}, \text{ otherwise} \end{cases}$$

Where,

$$\in = \begin{cases} 0.008856, \text{ Actual CIE standard} \\ \dfrac{216}{24389}, \text{ Intent of the CIE standard} \end{cases}$$

$$k = \begin{cases} 903.3, \text{ Actual CIE standard} \\ \dfrac{24389}{27}, \text{ Intent of the CIE standard} \end{cases}$$

$$L^* = 116 f_y - 16 \tag{2}$$

$$a^* = 500\left(f_x - f_y\right) \tag{3}$$

$$c^* = 200\left(f_y - f_z\right) \tag{4}$$

In RGB images there were three channels R, G, and B. But after converting into L*a*b* color spaces we get the values of three channels L*, a*, and b*.

C. Feature Extraction

RGB To extract features from the images of L*a*b* color space, mean and standard deviation has been calculated for each color channel. After calculating, we get mean of L* (M_{L*}), mean of a* (M_{a*}), mean of b* (M_{b*}), standard deviation of L* (Sd_{L*}), standard deviation of a* (Sd_{a*}), and standard deviation of b* (Sd_{b*}). Therefore, for classification using Q-SVM classifier, these mean and standard deviation values are used as features.

D. Q-SVM Classifier

Support Vector Machine (SVM) is a popular machine learning device that is considered as a nonparametric scheme because of using kernel function. SVM classification technique was developed by Vapnik [16]. For classification in our proposed scheme, the quadratic SVM technique has been used. In our observation we have n training data a_j, $a_j \in R^N$ for j=1,….n each either an ulcer or non-ulcer. Then as separating rule [17], [18],

$$\omega^T x \geq \gamma$$

Where, $x \in \mathbb{R}^N$ is a variable with $\omega \in \mathbb{R}^N$, $\gamma \in \mathbb{R}$ are the classifier parameters.

In our proposed scheme we have used kernel function denoted by $K(x_{ul}, x_{nul})$ where x_{ul} means ulcer and x_{nul} means non-ulcer data.

$$K(x_{ul}, x_{nul}) = (x_{ul}.x_{nul})^d$$

Where, d is the degree of the polynomial.

Now, to get $\omega and\ \gamma$ from the following equation,

$$\min_{\omega\in\mathbb{R}^N,\gamma\in\mathbb{R},y\in\mathbb{R}^n_+} \frac{1}{2} y^T D\left[K(x_{ul}, x_{nul})K(x_{ul}, x_{nul})\right]Dy - Ce^T y$$

Where,

$$\omega = y^T D[K(x_{ul}, x_{nul})K(x_{ul}, x_{nul})]Dy$$

$$\gamma = -e^T Dy$$

The classification has been implemented having five-fold cross-validation technique to split the samples into training and testing sets. After applying quadratic support vector machine classifier we are able to separate the ulcer and non-ulcer images.

III. Result and Discussion

A. Dataset Description

The WCE videos are collected from a publicly available database [13]. The initial process of this research work is converting the acquiring video footage from wireless capsule endoscopy to image frame according to the frame rate specified by capsule specification for further processing such as color space transform, feature extraction, and classification. Here used capsule endoscopy of PillCam®SB whose frame rate per second is 2 and battery life 8 hours that achieved a huge amount of data for analyzing. Among this we have used 245 color images where 110 ulcer and 135 non-ulcer images from 8 capsule endoscopy videos. Image frames in ulcer videos are manually vaccinated as ulcer or non-ulcer and if ulcer, the ulcer zones are marked by expert physicians.

B. Performance Measures of Ulcer Detection

The performance of our proposed method was determined using five parameter accuracy, sensitivity, specificity, precision, and f1-score. During the classification of ulcer and non-ulcer images, four types of occurrences may occur. The occurrences are true ulcer detection (T_{ulcer}), false ulcer detection (F_{ulcer}), true non-ulcer detection ($T_{non\text{-}ulcer}$), false non-ulcer detection ($F_{non\text{-}ulcer}$). Accuracy measures how to agree with the calculated value with true value. Hence, it measures how to correct a classification test due to a given condition. The numerical value of accuracy represents the ratio of true ulcer and non-ulcer detection with total observation. Sensitivity measures the correctness of ulcer detection. The numerical value of sensitivity represents the ratio of true ulcer detection with the true positive condition. The higher sensitivity shows more accurate ulcer detection. Specificity measures the correctness of non-ulcer detection. The higher specificity shows more accurate non-ulcer detection. Precision measures how to agree the calculate value among other calculated values. F1 score measures the correctness of the classification test. It is the harmonic mean of precision and sensitivity [19], [20].

$$\text{Accuracy} = \frac{\sum T_{ulcer} + \sum T_{non-ulcer}}{\sum T_{ulcer} + \sum T_{non-ulcer} + \sum F_{ulcer} + \sum F_{non-ulcer}} \quad (5)$$

$$\text{Sensitivity} = \frac{\sum T_{ulcer}}{\sum T_{ulcer} + \sum F_{non-ulcer}} \quad (6)$$

$$\text{Specificity} = \frac{\sum T_{non-ulcer}}{\sum T_{non-ulcer} + \sum F_{ulcer}} \quad (7)$$

$$\text{Precision} = \frac{\sum T_{ulcer}}{\sum T_{ulcer} + \sum F_{ulcer}} \quad (8)$$

$$\text{F1 Score} = \frac{2\times Sensitivity\times Precision}{Sensitivity + Precision} \quad (9)$$

Using equation (5), (6), (7), (8), and (9). we can calculate accuracy, sensitivity, specificity, precision, and f1-score respectively. First, after taking features from the RGB images we get accuracy 89.51%, sensitivity 87.44%, specificity 90.08%, precision 88.32%, and f1-score 87.49%. Then we get features from the images after converting into HSV, YCbCr, and L*a*b* color spaces for choosing better color space. The comparison has been shown in TABLE I. Though specificity and precision are higher in RGB color space. We affix on L*a*b* color spaces due to its higher accuracy, sensitivity and f1-score especially - accuracy 90.39%, sensitivity 99.00%, specificity 86.63%, precision 80.16%, and f1-score 88.50%.

TABLE I
Performance comparison with color spaces

Color Space	Acc. (%)	Sen. (%)	Spe. (%)	Pre. (%)	F1-Score
RGB	89.51	87.44	90.08	88.32	87.49
HSV	88.02	88.00	90.00	88.00	88.00
YCbCr	87.70	96.00	86.00	80.12	87.27
L*a*b*	**90.39**	**99.00**	**86.63**	**80.16**	**88.50**

Analysis has done for selecting the efficient classifier among Quadratic Discriminant Analysis (QDA), Quadratic Support Vector Machine (Q-SVM), Cubic Support Vector Machine (C-SVM), and Fine KNN classifier in RGB, HSV, L*a*b*, and YCbCr color space. Among these Quadratic Support Vector Machine (Q-SVM) in L*a*b* color space provide higher accuracy, sensitivity, and f1-score. For ulcer detection sensitivity is an important parameter for testing performance and also f1 score measures the correctness of classification test. So, for these reasons, we have to choose Q-SVM in L*a*b* color space.

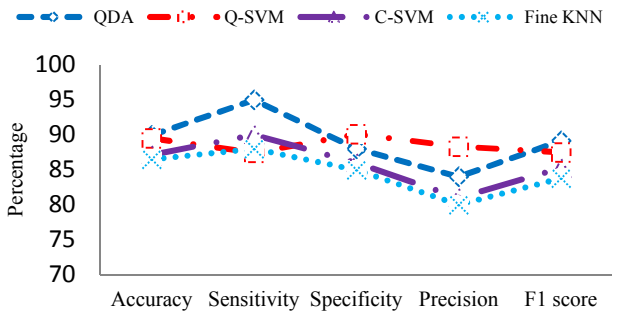

Fig. 3. Performance comparison varying classifiers in RGB color space

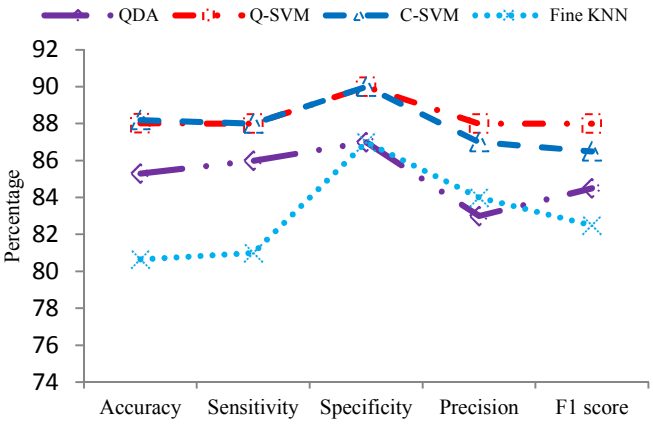

Fig. 4. Performance comparison varying classifiers in HSV color space

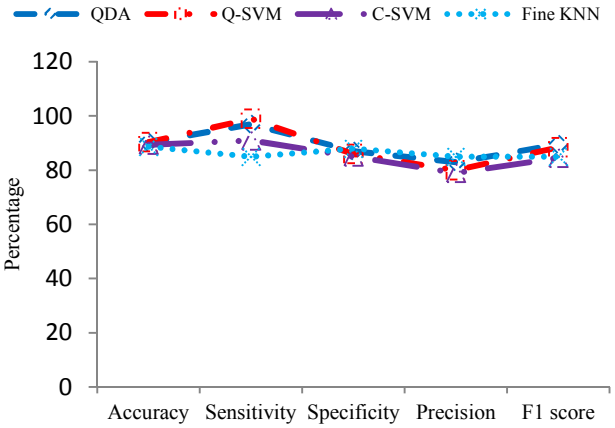

Fig. 5. Performance comparison varying classifiers in L*a*b* color space

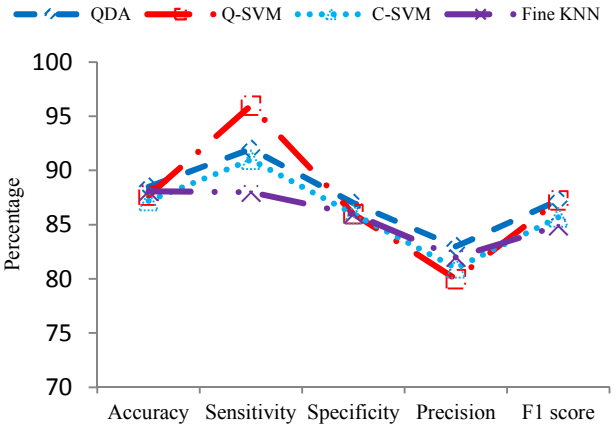

Fig. 5. Performance comparison varying classifiers in YCbCr color space

For feature selection we have chosen mean, median, min, max, moment, standard deviation, skewness, kurtosis etc. But mean and standard deviation of the values of L*, a*, and b* provide the best performance. Hence, we have used six types of features - mean of L*, a*, and b* with the standard deviation of L*, a*, and b*. By varying these all, we chose the combination of all the features which provides the best performance - accuracy 90.39%, sensitivity 99.00%, specificity 86.63%, precision 80.16%, and f1-score 88.50%.

Table II
Performance comparison varying features

FEATURES	ACC. (%)	SEN. (%)	SPE. (%)	PRE. (%)	F1 SCORE (%)
M_{a*}, M_{b*}, Sd_{L*} and Sd_{b*}	89.30	96.00	86.00	80.00	87.27
M_{b*}, Sd_{L*}, Sd_{a*} and Sd_{b*}	87.30	91.00	85.00	79.00	84.57
$M_{L*}, M_{a*}, M_{b*}, Sd_{a*}$ and Sd_{b*}	84.40	85.00	84.00	79.00	81.89
$M_{L*}, M_{b*}, Sd_{L*}, Sd_{a*}$ and Sd_{b*}	88.10	93.00	85.00	79.00	85.43
$M_{L*}, M_{a*}, Sd_{L*}, Sd_{a*}$ and Sd_{b*}	89.80	96.00	86.00	81.00	87.86
$M_{L*}, M_{a*}, M_{b*}, Sd_{L*}$ and Sd_{a*}	86.10	90.00	83.00	77.00	82.99
M_{L*}, M_{a*} and M_{b*}	77.00	75.00	78.00	72.00	73.45
$M_{L*}, M_{a*}, M_{b*}, Sd_{L*}$ and Sd_{b*}	89.80	95.00	87.00	82.00	88.02
$M_{a*}, M_{b*}, Sd_{L*}, Sd_{a*}$ and Sd_{b*}	88.10	95.00	84.00	77.00	85.06
$M_{L*}, M_{a*}, M_{b*}, Sd_{L*}, Sd_{a*}$ and Sd_{b*}	**90.39**	**99.00**	**86.63**	**80.16**	**88.50**

Mean of L* = M_{L*}; Mean of a* = M_{a*}; Mean of b* = M_{b*}; Standard deviation of L* = Sd_{L*}; Standard deviation of a* = Sd_{a*}, and Standard deviation of b* = Sd_{b*}

At last, the performance result of our proposed scheme has been compared with the performance of other methods of [5], [12], and [8]. Ghosh *et al.* method [5] features have been extracted from histogram bin frequency which was classified by KNN classifier. Kundu *et al.* method [12] were implemented via Y plane histogram with SVM classifier. Another method [8] has been proposed by Li *et al.* where CLBP technique has been used. Finally, our proposed scheme provides height accuracy and sensitivity over these all. TABLE III shows the comparison.

TABLE III
Performance comparison with other's method

	Accuracy (%)	Sensitivity (%)	Specificity (%)
Ghosh *et al.* [5]	87.27	88.64	85.75
Kundu *et al.* [12]	87.49	83.68	91.08
Li *et al.* [8]	89.20	87.53	91.46
Proposed Method	**90.39**	**99.00**	86.63

IV. Conclusion

In this paper, we proposed an easy technique with lower computational cost. This technique is a fully automated computer-aided system to diagnosis ulcer from WCE images. First, the RGB input image transformed into L*a*b* color space. Images at L*a*b* color space contains three components- L*, a* and b*. Then, the mean and standard deviation of each component has taken as features. The classification has done for separating ulcer and non-ulcer images applying Q-SVM classifier. Finally, the obtained performance – accuracy 90.39%, sensitivity 99.00%, specificity 86.63%, precision 80.16%, and f1-score 88.50%. Moreover, the comparison experiments showed that our method outperforms on others on the WCE ulcer classification.

***Abstract*—Brain computer interface (BCI) is an interconnecting scheme between human brain and computer which entitles humans to interact with their environs by their brain waves instead of muscle activities. In the age of new argumentative technology, EEG signals are extensively employed in the involvement of BCI. The key motive of the work is to investigate EEG activities during imagination of hand movements. BCI competition IV dataset 2a were studied as well as analyzed in this research. We have detected the event related desynchronization and synchronization of mu and beta rythms during hand imagery movements by Power Spectral Analysis (PSA), Event Related Potential (ERP) plots, ERP comparison, Time-Frequency Analysis. Mainly, the EEG rhythms recorded at channels C3 and C4 are investigated. Results of this paper show that imagery movement of hands is usually associated with decrement in mu and beta rhythms, which is typically adversary to the moving activities. Our results are compatible with previous motor imagery researches and are of practical interest for the evolvement of BCI for motor reclamation.**

Keywords—brain computer interface, EEG signals, event related desynchronization, event related synchronization, motor imagery

I. INTRODUCTION

Electroencephalogram (EEG) is the representation of electrical activities of the brain from the scalp. The EEG signal's patterns and parameters imply the health condition of the brain. Therefore, proper investigation of EEG plays a significant role in brain studies. EEG signals contain a wide range of frequency bands. There are mainly five types of brain waves (EEG waves): δ waves (0.4-4 Hz), θ waves (4-8 Hz), α waves (8-13 Hz), β waves (13-30 Hz), and γ waves (30-100 Hz). Besides this, the motor cortical areas of brain mostly reveals 8-12 Hz EEG activities, called Rolandic μ rhythms and are commonly accompanied with 18-26 Hz β rhythms. μ rhythms (8-12 Hz) are influenced by movements or imagination of movements. Particularly, the assessment of EEG waves has been become intensively familiar to identify the difficulties of extracting the knowledge of the brain signals. One of the major applications of EEG waves is in BCI.

BCI is a direct connecting way between brain and exterior machines. BCI associates the brain activity to an external computer, as shown in Fig. 1, which enables an individual to control devices straightly with his brain waves (EEG waves) and without using his muscles. Now-a-days, controlling device with the aid of BCI has become an ultimate substitute for those who are paralyzed or suffering from crucial motor disabilities. Besides this, the EEG based BCI can be utilized in different home appliances, environment control etc. A BCI system translates reactivities of the EEG signals into a command to conduct an exterior machine fulfilling the task of an interaction [1]. This translation involves proper and efficient recognition of the user intension's patterns of the brain by proper investigation and careful analysis of EEG waves. Therefore, investigation and analysis of the recorded EEG signals by appropriate techniques are of great importance to get the powerful BCI.

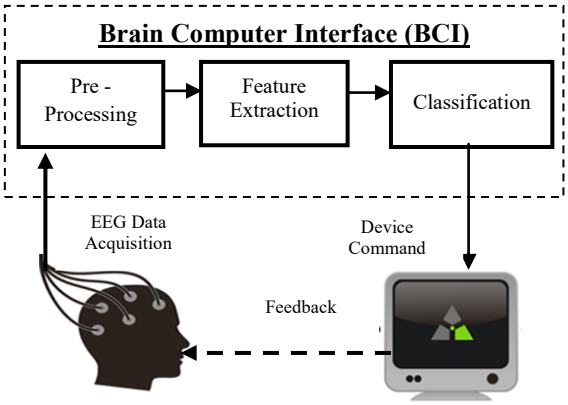

Fig. 1. Simplified block diagram of EEG based BCI.

A variety of studies have been done in order to extract information of the brain waves for robust BCI research. Over the past two decades, imagination of movements has become most popular to design EEG-based BCI systems. This entitles motor disable person to operate several BCI devices like wheelchairs [2], prosthetic devices [3], and computers [4]. Several studies have revealed that motor disable person or normal person can able to govern the amplitude of μ or β rhythms in EEG waves stored from the scalp over sensorimotor area [5]. Varity of factors suggest that the event-related desynchronization (ERD) are the decrease that appear when thinking about the movement or performing the movements. ERD begins while the subject initiates to think of a movement and reveals it as a potential desynchronization in μ and/or β rhythms. In case of motor imagery, ERD occurs in the contralateral hemisphere and event-related synchronization (ERS) occurs in the ipsilateral hemisphere. Analysis of EEG signals for BCI includes preprocessing, feature extraction techniques and classification [6, 7]. Supervised classification methods are employed to realize the mapping in between EEG waves and classes resembled to mental events [8, 9]. It was proposed that the ERD and ERS can be significant classification features for the motor imagery EEG waves [10].

In this research work, we investigate the ERD/ERS of EEG signals (μ and β rhythms) by Power Spectral Analysis (PSA), Event Related Potential (ERP) plots, ERP comparison, Time-Frequency analysis, etc. which will

indicate that EEG activity during imagery movements may be employed in a motor conducted BCI.

II. Materials and Methods

This research work has been carried out in several steps as shown in following Fig. 2.

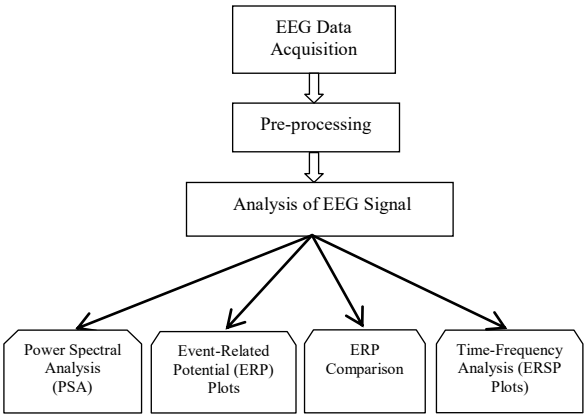

Fig. 2. Working steps.

A. Data Acquisition and Description:

In our research, the motor imagery EEG data have been taken from BCI competition IV dataset 2a provided by Graz for investigating EEG activity during imagination of movements. In this BCI dataset, EEG data are provided for 9 subjects. The BCI illustration was cue based and the data are taken for four different motor imagery tasks, such as left hand imagery movement (class 1), right hand imagery movements (class 2), both feet movements imagination (class 3), and imagery tongue movements (class 4) [11]. 22 Ag/AgCl electrodes were used to record the EEG in international 10-20 system, as shown in Fig. 3.

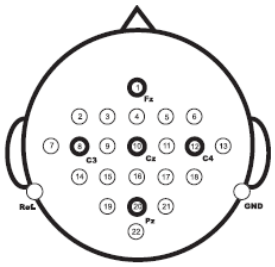

Fig. 3. Channel locations of the recorded EEG signal [11].

The signals were sampled with 250 Hz. In this database, EEG data are provided in the General Data Format (GDF) for each subject as well as session. Here, class labels are stored for only one session for all trials, but another session is imported to evaluate performances. We have used only the training datasets for 9 subjects. The events for four classes of data are shown in TABLE I.

TABLE I. DESCRIPTION OF DATA

Event	Description
769	Left hand imagery (class 1)
770	Right hand imagery (class 2)
771	Foot imagery (class 3)
772	Tongue imagery (class 4)

We have investigated the data for events of 769 and 770 corresponding to right and left hand imagery movements.

B. Pre-processing:

We have used EEGLAB (an open source tool box) provided by SCCN lab, running under the cross platform MATLAB for pre-processing of EEG data. The pre-processing steps are shown in Fig. 4.

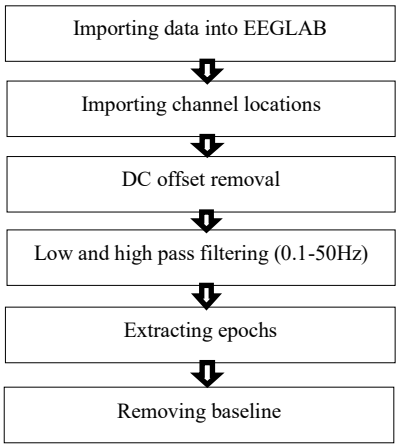

Fig. 4. Steps of pre-processing.

Firstly, the GDF data files have been imported into EEGLAB with the BioSig toolbox using EEGLAB function and plugin and then the channel locations are edited according to the electrode positions which was used to record these data as described before. After editing the channel locations, the channel data have been plotted for visualization and the DC offsets have been removed. DC offsets initiates filter artifacts at signal borders. So, it is better to remove them prior filtering. To dispel linear trends, the data have been then filtered. The data is then high-pass filtered with lower cut-off frequency of 0.5 Hz and after that low-pass filtered with cut-off frequency of 50 Hz by using Linear FIR filter [12]. This filtering of EEG data eliminated the noise and artifacts. Then we have extracted epoch corresponding to the event of right hand imagery (770) and left hand imagery (769) followed by baseline removal. We have extracted epochs from 1s before the event and 2s after the onset of event, and then EEG signals are analyzed. Thus, we have obtained the epochs of two events-

- Imagination of right hand movement (event 770)
- Imagination of left hand movement (event 769)

C. Analysis of EEG Signal:

After pre-processing, we have investigated the extracted epochs by different analysis:

1) Power Spectrum Analysis (PSA): Power spectral analysis is a well-known scheme for the analysis of EEG signals. Power Spectral plot is a colored trace which indicates signal power spectra of the activity of the channels along the range of the frequencies with colors. In our research, we have used EEGLAB to investigate the power spectrum of the selected epoch at chosen frequency. Thus, we have investigated the active part of the brain during right arm and left arm imagery. Here, the scalp distribution of power was observed by plotting the power spectral of epoched data at 4, 8, 10, 12, 18, 20, 22, 40 Hz as we have

investigated the ERD/ERs of μ (8-12 Hz) and β (18-26 Hz) rhythms, we have taken the value of frequencies of these types. Here, the channel spectra and maps have been plotted for electrode positions C3 (left side motor area) and C4 (right side motor area).

2) Event-Related Potential (ERP) Plots: An event-related potential (ERP) is the observed brain stimulus which is the direct outcome of a particular motor work. The electrophysiological data analysis mostly uses dimensional event-related potential (ERP) averages. EEGLAB provides various ERP image for realizing the motive of ERP effects. ERP-image plots are 2-D view (trial-by-trial) of the event-related data epochs in which data epochs are first sorted along some relevant dimension then smoothed and finally color-coded and imaged. In this research work, we have investigated the epoched data for two different events by plotting ERP images. ERP averages have been also utilized for the comparison of the event related potentials.

a) Channel ERP Image Plots: ERP image plot facilitates trial by trail views of a set of data epochs. An ERP image is a colored rectangular image where every single horizontal line is used to represent a potential time series for every experimental test. In our thesis, we have studied ERP image plot for channel C3 and C4 during right hand and left hand imagery where we have used the smoothing 10, down-sampling 1 and time limits 1000ms to 1996ms.

b) ERP Comparison: To make our analysis more significant, we have compared the ERPs in two different events. ERP averages have been used to compare the ERPs. We have compared the ERP of channel C3 and C4 to differentiate ERD and ERS during imagination of right hand and left hand movements.

3) Time-Frequency Analysis (ERSP Plots): When the information about changes in frequency is unknown, time-frequency analysis plays a crucial role for analyzing EEG data [13]. Event-related spectral perturbation (ERSP) and inter-trial coherence (ITC) are two methods for time or frequency decomposition, used in the basic EEGLAB. In our work, we have used ERSP plot method. ERSP quantifies the mean event variation in power spectrum at a data electrode. The synchronization as well as desynchronization of events which are narrowband was visualized by ERSP plots [14]. An ERSP can be calculated by following equation.

$$ERSP(f,t)=\frac{1}{n}\sum_{k=1}^{n}\left|F_k(f,t)\right|^2 \quad (1)$$

Here, n stands for number of trials, $F_k(f,t)$ stands for spectral estimation for k^{th} trial, f stands for frequency and t stands for time. In this research, we have used ERSP method to quantify the mean event variation in power spectrum at data electrode positions C3 and C4 for right hand and left hand imagination movements.

III. Results and Discussion

A. Power Spectral Plots:

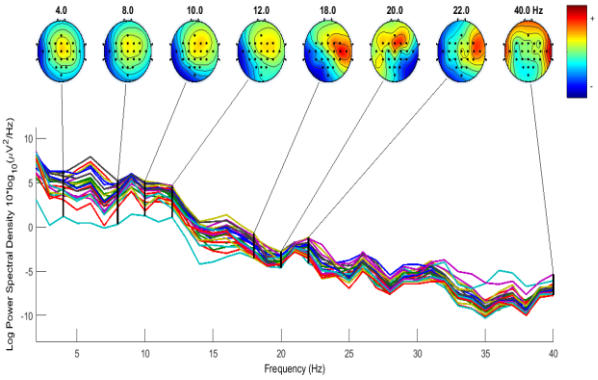

Fig. 5. Power spectral plots during right hand imagery movements at 4, 8, 10, 12, 18, 20, 22, 40 Hz.

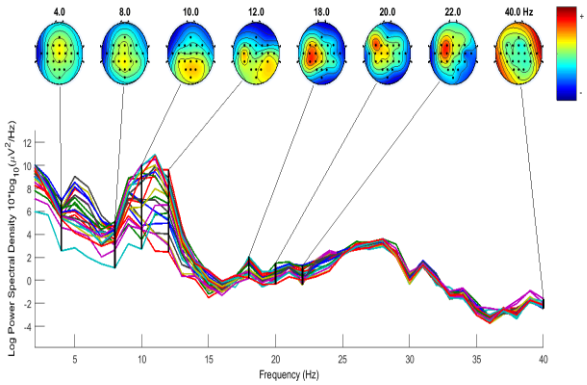

Fig. 6. Power spectral plots during left hand imagery movements at 4, 8, 10, 12, 18, 20, 22, 40 Hz.

Figs. 5 and 6 show the results of power spectral plots of EEG data during right hand imagery and left hand imagery at 4, 8, 10, 12, 18, 20, 22, 40 Hz. In power spectral plot of right hand imagery (Fig. 5), a decrease in the spectral can be shown near C3 electrode positions position (left side sensory motor area) at 8-12 Hz, 18 Hz and 22 Hz. It means a reduction in power spectrum can be seen in the left side of the brain which is represented by the blue color. Therefore, power spectrum in right side brain is relatively high and it is indicated by red color. In power spectrum during left hand imagery movements (Fig. 6), a decrease in the spectral (blue color) can be shown near C4 at around 12 Hz and 18-22 Hz which means lower power spectrum in the right hemisphere of the brain. Eventually, high power spectrum (red color) can be seen in left side motor area of the brain.

In frequency domain, ERD is identified by a decrement in the spectral power. Eventually, ERS means a high power spectrum. Therefore, the results show ERD in left side brain and ERS in right side brain during right hand imagery. Oppositely, during left hand imagery, an ERD is shown in the right side motor area and an ERS in left side motor area of the brain.

B. *Channel ERP Image Plots:*

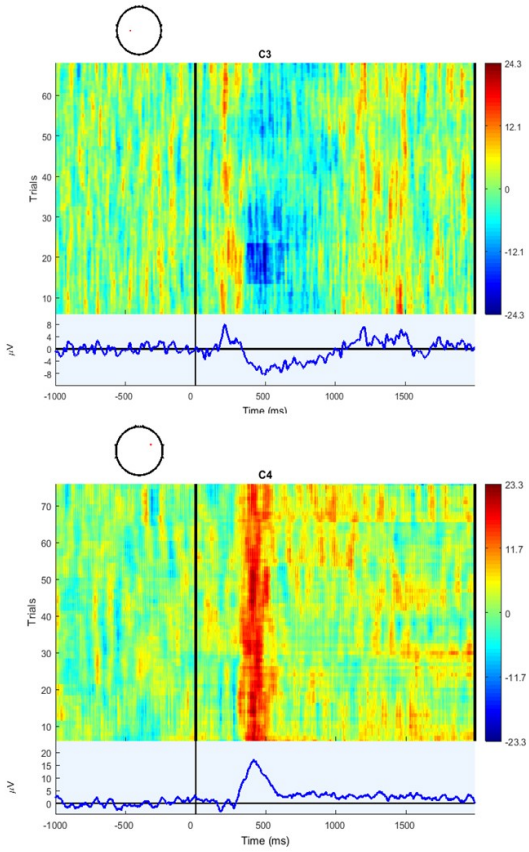

Fig. 7. Channel ERP image at electrodes C3, C4 during imagination of right hand movements.

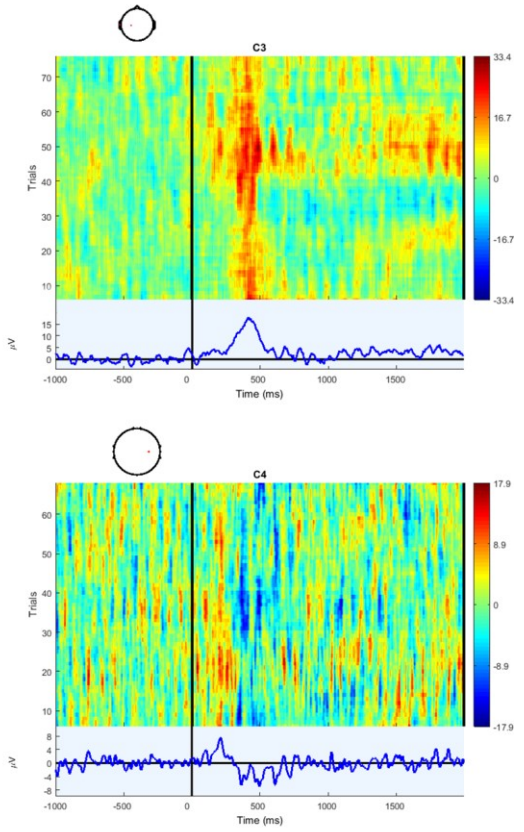

Fig. 8. Channel ERP image at electrodes C3, C4 during imagination of left hand movements.

Figs. 7 and 8 show the result of channel ERP image plots. In our research, the channel ERP images are plotted for right hand and left hand imagination at electrode positions C3 and C4. In case of right hand imagery movements (Fig. 7), the channel ERP image at electrode positions C3 (left side sensory motor area of the brain) shows a decrement in ERP at around 400ms after starting of event which indicates the ERD of μ and β rhythm. In color plot, this desynchronization is represented by blue color. Eventually, an increase in ERP at near 400ms is observed in right side brain (channel C4). Similarly, when we consider about left hand imagery movements (Fig. 8), channel ERP image of electrode positions C3 shows an ERS (red color) around 400ms after starting the event. On the other side, the channel ERP of C4 shows a decrease in ERP at 400ms. The result is summarized in the TABLE II.

TABLE II. ERD/ERS DURING IMAGERY MOVEMENTS

S	Motor Imagery	ERD	ERS
1	Right hand movement	Left side motor area of the brain	Right side motor area of the brain
2	Left hand movement	Right side motor area of the brain	Left side motor area of the brain

C. *Comparison of channel ERPs:*

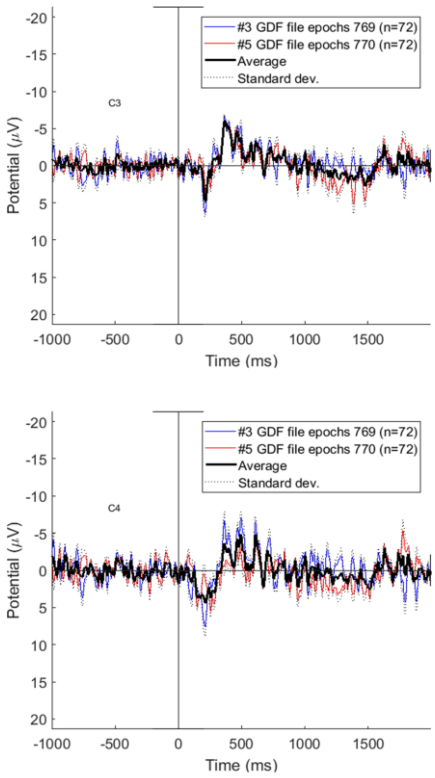

Fig. 9. Comparison of channel ERPs of right and left imagery at electrodes C3, C4.

Comparisons of channel ERPs are also plotted for the electrode positions C3 and C4 respectively which is shown in Fig. 9. The channel ERPs are also compared so that we can strengthen the result obtained from channel ERP images for right hand and left hand imagery at channel C3 and C4.

D. Time-Frequency Analysis (ERSP Plots):

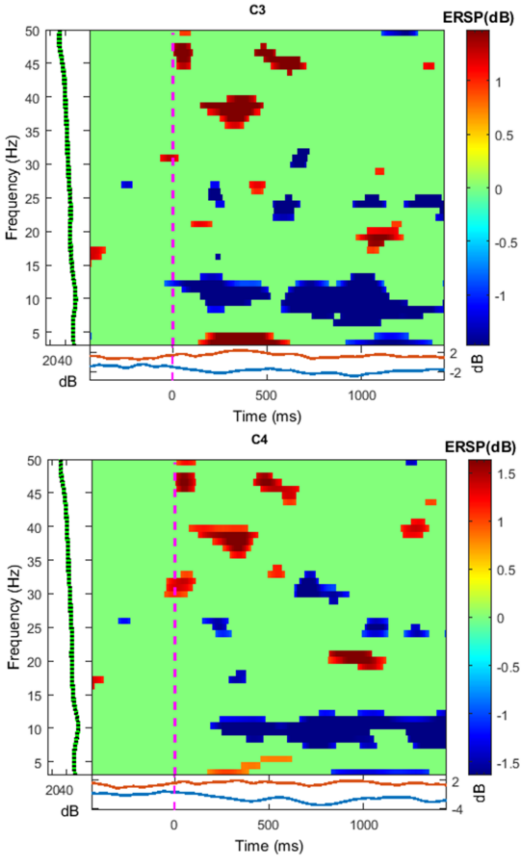

Fig. 10. ERSP plot during right hand imagery movements at channel C3 and C4.

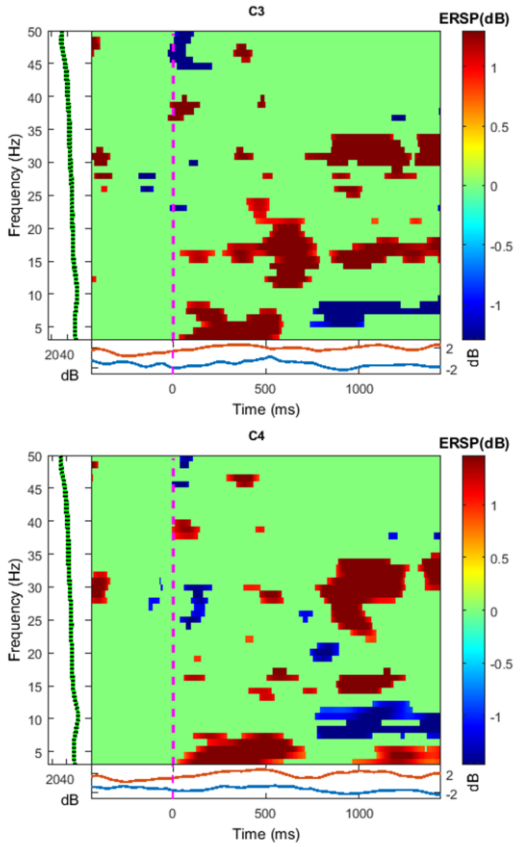

Fig. 11. ERSP plot during left hand imagery movements at channel C3 and C4.

Figs. 10 and 11 represent the ERSP plots at channel C3 and C4 during right and left hand imagery movements respectively. In Fig. 10, the ERSP plot of C3 electrode (left side brain electrode) during right hand imagery shows a decrease in the spectral power (represented by blue color) around 400-500ms after the onset of event related potential around μ rhythm (10-12 Hz). Again, the ERSP plot of channel C4 shows an enhancement around 400-500ms at 10-12 Hz. Fig. 11 shows the ERSP plot of C3 and C4 electrodes during left hand imagery. At channel C4, a decrease in the spectral power can be observed around 400-500ms after the onset of event related potential around 10-12 Hz. And again, at C3, an increment can be seen around 500ms at 10-12 Hz. The result of ERSP plots demonstrates the desynchronization of mu rhythms in the respective hand areas for hand motor imagery.

All of our analyses have given the consistent results for both hand imagery movements which are very much significant for our research. Also, our results are compatible with previous motor imagery researches and are good enough compared to some other previous motor imagery results. In 2008, the ERD and ERS of μ and β rhythms were analyzed by Yeom and Sim during imagery movements of arms [16]. But in that research, only PSA and ERSP plots are used which limits practicability. In our research, more analyzing methods have been used. In 2009, Varghese analyzed motor imagery data during left hand and right hand movements and got significant results [17]. Our hand imagination results are coincided with the research and our classification results are more indicative. In 2016, hand movement motor imagery EEG was studied by Shah and Nayak, where 'BCI competition II' dataset were utilized [18]. In our research, 'BCI competition IV dataset 2a' are used which have shown better results. Moreover, our motor imagery hand movements results are coincident with those reported by Farland et al. [19], Pfurtscheller et al. [3], and Sivakami and Devi [20].

IV. Conclusion

In this work, we analyzed the motor imagery data of 'BCI competition IV dataset 2a' [11] provided by Graz during visualization of right arm and left arm movements using EEGLAB, an open source toolbox running under MATLAB. We have investigated that how EEG activity changes with imagery movements by differentiating ERD and ERS of μ and β rythms. The result of this research substantiated that imagination of hand movements is generally associated with ERD in μ and β rhythms, typically adversary to the movements. The major significance of our research is that by our results, we are able to differentiate the features of μ and β rhythms occurring in sensory motor cortex during hand imagery by ERD/ERS quantifications. Also, our analyses give compatible results which are very much important for BCI implementations.

In future, we will try to convert these significant findings into BCI commands and thus conduct a device, such as, wheelchair, only by motor imagery EEG waves for disabled people.

***Abstract*— The biometric method which is involved with defining pattern of movement of human limbs is called Gait. Though gait has a fixed rhythmic pattern, in case of people who are affected with neurological disease such as- Parkinson's disease (PD) the gait pattern gets distorted from normal gait pattern. In this paper, temporal variables of gait cycles are analyzed to determine the deficit in the gait cycle in PD patients. Gait cycle of 10 PD patients and 10 Controlled subjects are examined in this paper. A comparative analysis was done in respect of temporal variables such as- Single Limb Support Time and Double Limb Support Time. From the examination and investigation, it is apparent that the temporal factors of the gait cycle of PD patients are sufficiently changed in regard to the controlled subjects, all the more explicitly PD patients invest more energy in the two limbs than a single limb of a gait cycle which is absolutely in switch of the controlled subject.**

Keywords*— *Parkinson's Disease, Gait Analysis, Temporal Variables, Signal Processing, Limb Support Time

I. Introduction

Parkinson's disease which was first discovered by Dr. Parkinson is a chronic neurological disorder which predominately occurs in elderly people and associated with different neurological difficulties [1], [2]. From an in-depth survey, Parkinson's foundation stated that about 10 million people are affected by Parkinson's disease around the globe [3].

Neurons found in Substantia Nigra, a region in the brain gets infected as a result of Parkinson's. These neurons are responsible for creating dopamine which in turn controls limb movement of a human. As dopamine secretion gets distorted due to damaged neurons, the people affected by Parkinson's lose control over their movement [3]. A person affected with Parkinson's may suffer from different difficulties such as- Tremors, Muscle rigidity etc. [4]. A common phenomenon occurs among Parkinsonians is the loss of control over the gait cycle.

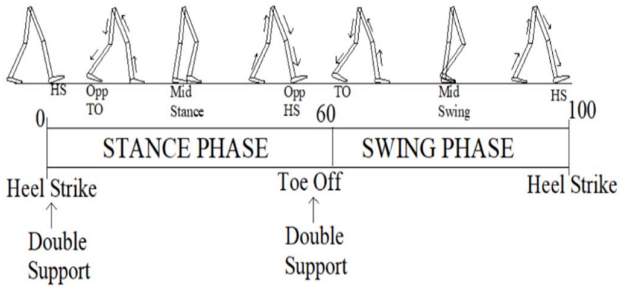

Fig 01- Illustration of Gati Cycle [HS=Heel Strike, TO=Toe Off, Opp=Opposite] [5]

Gait cycle is commonly defined as the walking cycle. In Fig. 01 a typical gait cycle is being portrayed, where stance phase (60% of gait cycle) of gait cycle is started when heel strikes and ends up when the toe is off to the ground and then swing phase (40% of gait cycle) starts [5]. Gait cycle is an important parameter to study human movement especially in the case of Parkinson's affected person. The extent of distortion can be determined by analysis of gait cycle.

The Gait Cycle can be described through two parameters: Spatial Variables and Temporal Variables. Spatial variable defines the gait cycle in terms of step length and stride length. Whereas, the temporal variable consists of several parameters: Single Limb Support Time, Double Limb Support Time and Speed. Single limb support time is defined as the time in which only one foot acts as body support. On the other hand, when body mass is carried by both feet the situation is considered as double limb support. The time spent in this posture is considered as double limb support time. In Fig. 02, temporal variables of gait cycle have been depicted.

Parkinson's disease is associated with different movement deficiencies. As Parkinson's is a chronic and long term disease, along with the time the disease gets more prominent and thus affects Parkinsonians lifestyle [7]. The Parkison's disease is responsible for truncated stride length, low walking speed and buffed double support phase [8], [11]. The situation can be improved by employing external influences such as cues [9]-[11].

There have been quite a number of studies on Parkinson's gait analysis but few of those studies focused on kinetic parameters. In one of the studies based on kinetic features, the authors examined patients under influence of external cues to rectify the spatiotemporal and kinematic parameters [12].

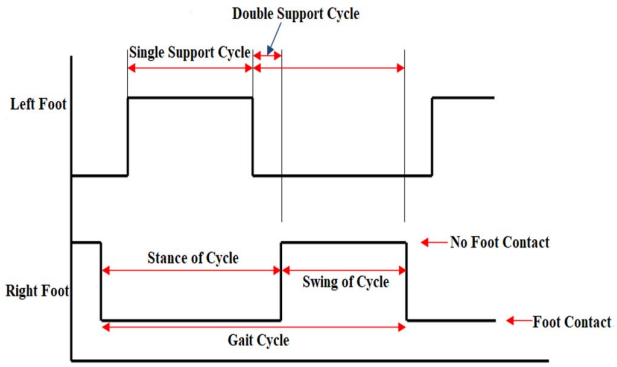

Fig. 02- Illustration of Limb Support Time [6]

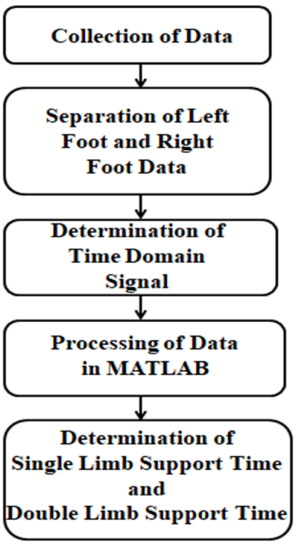

Fig. 03- Overview of Proposed Technique

Lewis showed that there is a large amount of variability present in kinematics and kinetics [13]. A quantitative analysis of gait was performed to show the difference between dopa-sensitive and dopa-resistance kinematic gait parameters. The result showed that the temporal variables are related to dopa-resistance [7]. The study lacked clarification in case of specific gait cycle parameter.
Another researcher observed an altered gait pattern in Parkinsonians. They showed that there is asymmetric timing and increased variability in gait which can be regarded as principal evidence of motor programming deficit in gait due to Parkinson's [14]. After that, it was observed that the movement time of PD patients is greater than the controlled healthy subject. External cues can improve temporal variability in case of Parkinson's disease affected person but still, there was evidence of distortion from normal subject [15]. Another researcher Pasluosta proposed a time series approach to focus on the human gait characteristics that shows a few unnecessary occasions, which are basically gait signals with pseudo-tedious nature [16]. On the other hand, researcher Chen depicted different methods for recognizing critical gait occasions which are recurring [17]. Besides, Mirelman investigated a unique signal for identification of specific parts of body with gait stability and normality [18].

In this paper, a method is proposed to quantify the gait cycle fluctuations of Parkinsonians in terms of temporal variables like- single limb support time, double limb support time and speed. The analysis also consists of a comparative study of temporal variables between controlled subjects and Parkinsonians to portray the difference between healthy subject and parkinsonians.

II. Methodology

The proposed procedure can be separated into three sections: Data Collection, Analysis of Data and Comparative Study between Healthy Subjects and Parkinson influenced people. The overall components of this investigation are portrayed in Fig. 03.

The data acquisition part comprises the gathering of information from Physionet Database named Gait in Parkinson's disease [19]. The obtained signals are vertical ground reaction force signals. The signals are fetched from 16 sensors divided into two equal number portions placed beneath both the right and left foot. The acquired data are separated into left foot and right foot data. The information is investigated independently in MATLAB to decide Time Domain Signal. By analyzing the stance phase and swing phase, it is discovered that there are just two positions in a Gait cycle when a subject needs double limb support: Heel strike position and Pre-swing Position. In light of these perceptions, time for single limb support and double limb support are determined for concerned subjects. For double limb support time, the vertical ground reaction force of left foot and the vertical ground reaction force of right foot must be greater than zero because both feet must exert the force on the ground on this case. Utilizing this logic, a square wave is created which represents double limb support. Then, difference equation topology is applied to generate a spike which represents changes of square waves of two foot. Basically, for a gait cycle, four spikes are found because in one gait cycle there are two positions when a person is in double limb support and for one double limb support there are two spikes. By using this logic, the index of the spikes is found and then the index of the first spike is subtracted from the second spike and again the same procedure is followed for fourth spike and third spike. After that, both index differences are added. As the sampling rate (100Hz) is known beforehand from the data website, the index is divided with sampling frequency to get the double limb support time. Single limb support time for a gate cycle is the difference between the stride time of a foot and double limb support time. Stride time of a certain foot is calculated by using the difference between the indexes of consecutive steps.

III. Result and Discussion

A. Data Delineation

Total data of 20 subjects were taken from the database. Among 20 subjects, 10 of the subjects were affected by Parkinson's and the rest 10 people were controlled subjects. The gender of considered subjects is male. The subjects were not under any external cues during the data acquisition phase. The age range of Parkinson's disease affected subjects is between 55 years to 70 years, whereas, the controlled subjects age spans from 60 to 75 years.

Table I: Temporal Data of Controlled Subjects

Controlled Subject Number	Mean(Double Limb Support Time) (second)± Variance	Mean(Single Limb Support Time) (second) ± Variance	Speed (m/s)
Subject 1	0.2949±0.0152	0.9518±0.0081	1.051
Subject 2	0.2338±0.0038	0.9434±0.0015	1.121
Subject 3	0.2093±0.0011	0.8595±0.0011	1.164
Subject 4	0.3112±6.6859e-04	0.9232±5.0630e-04	1.073
Subject 5	0.2441±9.9912e-05	0.8825±2.0202e-04	1.16
Subject 6	0.2901±2.7856e-04	0.9299±5.0205e-04	1.00
Subject 7	0.3073±5.2308e-04	0.8776±9.4772e-04	0.99
Subject 8	0.2014±4.7058e-04	0.8512±5.0585e-04	1.29
Subject 9	0.1918±0.0022	0.8254±0.0013	1.515
Subject 10	0.1720±0.0053	0.9262±0.0046	1.415

Table II: Temporal Data of Parkinson's Patient

Parkinson's Patient's Number	Mean(Double Limb Support Time) (second)± Variance	Mean(Single Limb Support Time) (second)± Variance	Speed (m/s)
Patient 1	0.8388±0.0012	0.3177±0.0023	0.848
Patient 2	0.9830±0.0013	0.2705±9.7951e-04	0.802
Patient 3	0.8044±0.0042	0.3111± 0.0043	0.987
Patient 4	0.8690±0.0025	0.3667±0.0034	0.825
Patient 5	0.9113±5.8292e-04	0.1941±9.9563e-04	1.013
Patient 6	0.7786±0.0032	0.2657±0.0033	0.832
Patient 7	0.7179±0.0086	0.2500±0.0044	0.785
Patient 8	0.8202±0.0080	0.2047±0.0057	1.112
Patient 9	1.0127±0.0229	0.5070±0.0291	0.413
Patient 10	0.7657±0.0053	0.2186±0.0063	0.894

The collected data were then converted into temporal variables such as- Single limb support time, Double limb support time and Speed. The temporal data are presented in Table-I and Table-II. Table-I represents controlled subjects and Table-II narrates data of Parkinson's disease affected persons and Table-III demonstrates the comparative study of temporal data. The single limb support time and double limb support time data for all subjects are depicted in Fig. 04 and Fig. 05. Fig. 04 illustrates data of controlled subjects, whereas, Fig. 05 delineates data of Parkinson's affected patients.

B. Comparative Analysis

After calculating the temporal variable data, the time required for single limb support and double limb support were compared between healthy controlled subjects and disease affected subjects.

The limb support times of controlled subject 01 and 02 are elucidated in Fig. 06 and Fig. 07. It is visible that single limb support time is greater than double limb support time in case of the controlled subject which validates the observation where it was found that only two positions in a gait cycle are based on double limb support. In Fig. 06, it is observed that for controlled subject 01 single limb support time is in between 0.3s to 1.1s with mean value 0.9518s and double limb support time is in between 0.2s to 1.2s with mean value 0.2949s. Similarly, in Fig. 07 for controlled subject 02 single limb support time is in between 0.75s to 1.5s with mean value 0.9434s and double limb support time is in between 0.19s to 0.55s with mean value 0.2338s, whereas, the speed of controlled subject 01 is 1.051m/s and controlled subject 02 is 1.121m/s.

Fig. 08 illustrates the temporal variables for Patient-03 which shows that the double limb support time is higher than single limb support time. The mean values of times are 0.8044s and 0.3111s respectively for double limb and single limb. The average speed clocks at 0.987m/s which are evidently lower than controlled subjects.

Table III- Comparative Analysis of Temporal Data

Subject	The range of Double Limb Support Time (second)	Range of Single Limb Support Time (second)	The range of Speed (m/s)
Controlled Subjects	0.1720-0.3112	0.8254-0.9518	0.99-1.515
Patients	0.7179-1.0127	0.2047-0.3667	0.413-1.112

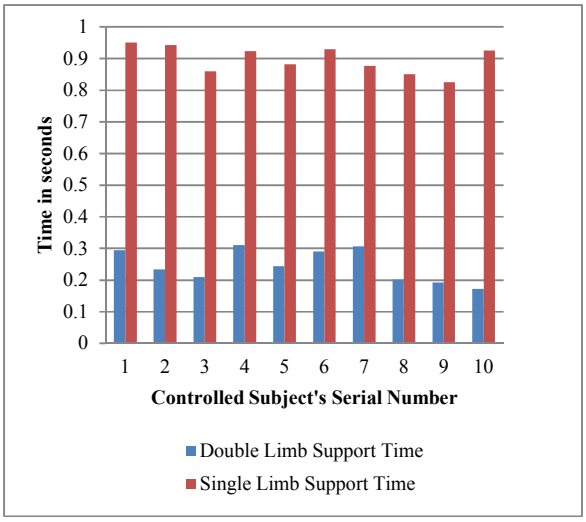

Fig. 04- Temporal Variable Data of Controlled Subjects

Fig. 09 renders the single limb support time and double limb support time for Patient 10. The figure shows that the mean value of time taken for single and double limb support is 0.2186s and 0.7657s respectively, whereas the calculated average speed is 0.894m/s.

From Fig. 6 – Fig. 9, mean value of the single limb support time and double limb support time are shown and it is noticeable that for the healthy subjects (Fig. 6 and Fig. 7) the single limb support time and double limb support time vary closer to their mean but in case of the Parkinson's patients (Fig. 8 and Fig. 9) they vary a lot from the mean.

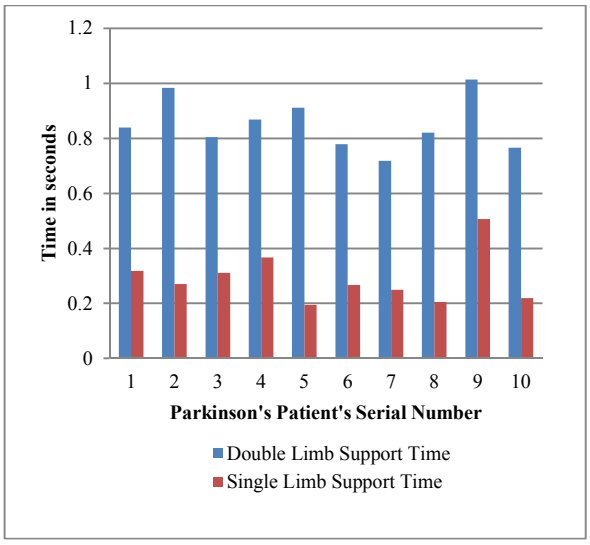

Fig. 5- Temporal Variable Data of Parkinson's Patients

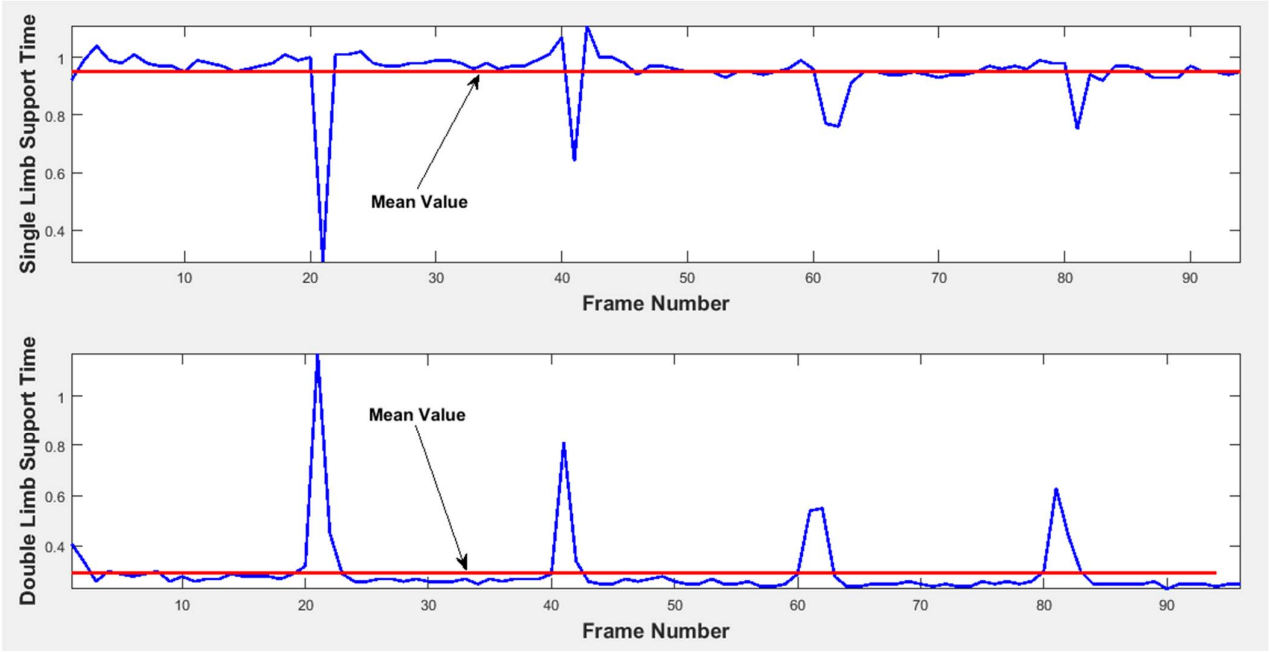

Fig. 06- Limb Support Time of Controlled Subject 01

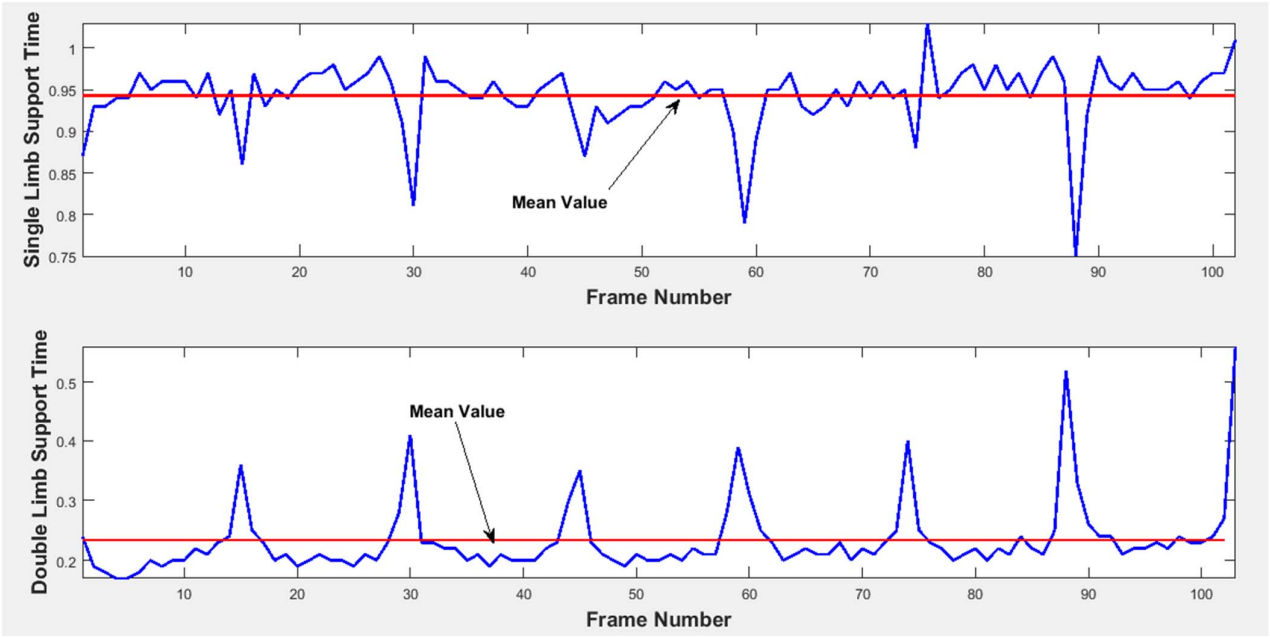

Fig. 07- Limb Support Time of Controlled Subject 02

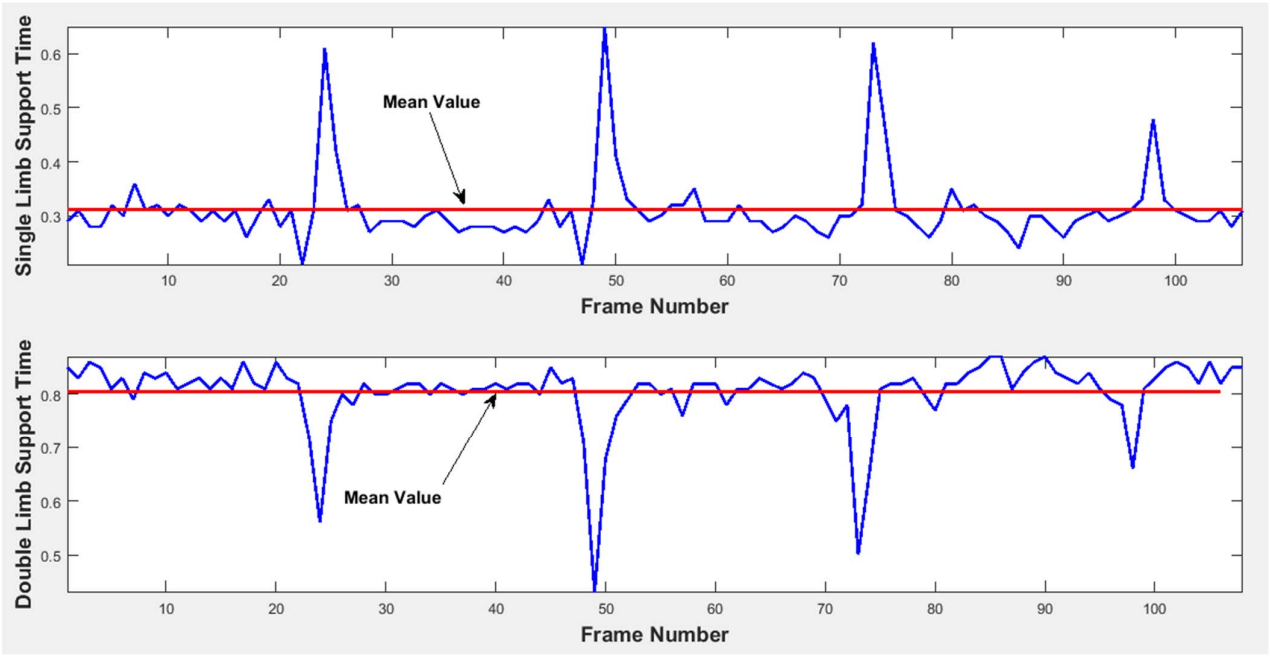

Fig. 08- Limb Support Time of Patient 03

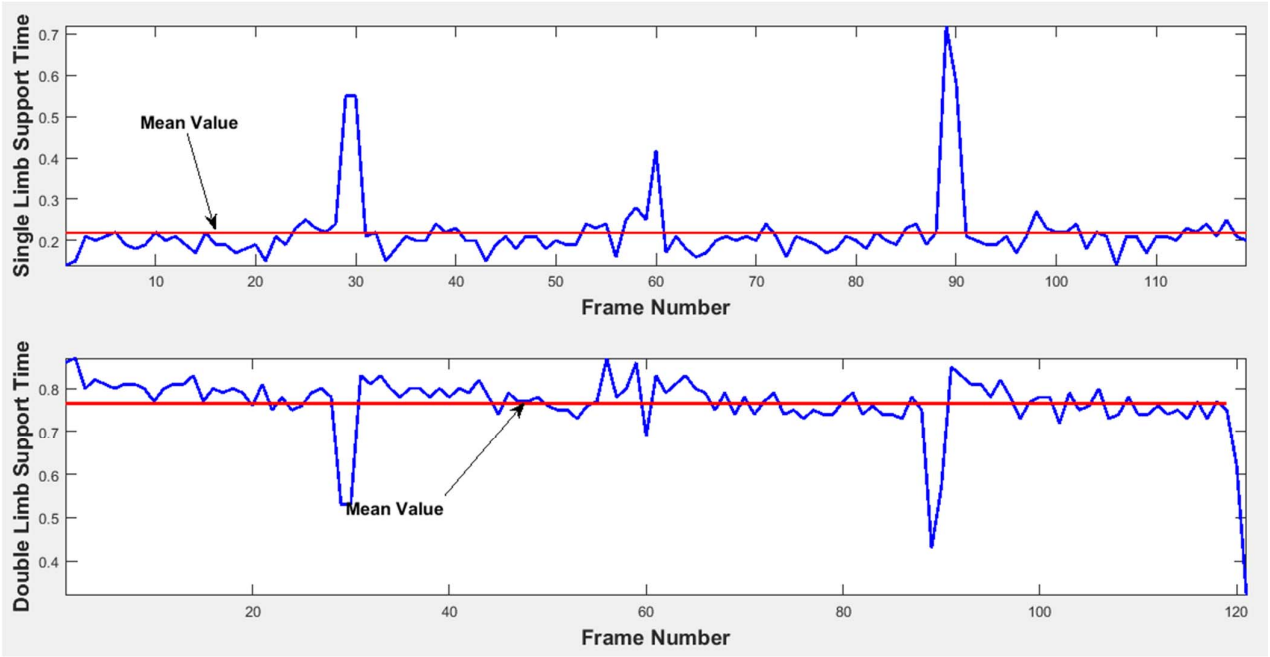

Fig. 09- Limb Support Time of Patient 10

From the precedential analysis, it is evident that double limb support time is higher than single limb support time in case of Parkinson's disease affected persons. The opposite is seen in the case of controlled subjects. The speed of Parkinson's affected subjects is lower than controlled subjects. Table-III shows discrimination among the range of temporal variables. All these data prove that the patients suffering from Parkinson's suffer greatly due to gait cycle distortion.

The results found in this comprehensive study based on temporal variable might be proved to be vital in case of assessment of gait cycle variation in Parkinsonians. In future, these data can be used with Machine Learning algorithms to predict the trend of a patient affected with Parkinson's and provide external cues according to the needs of the patient.

IV. Conclusion

In this study, a comparative analysis of temporal variable data of Parkinson's affected patients and controlled subjects are depicted. By juxtaposing all calculated data, it is discernible that the double limb support time in case of Parkinsonians is greater than controlled subjects. The reason behind this distortion is related to loss of control over the gait cycle in case of Parkinson's disease affected persons. The loss of walking speed is also visible for Parkinson's affected person. The results of this study can be used to develop assistive devices with feedback for Parkinsonians. Also, the result in conjecture with spatial variables could provide more accurate situation assessment for patients affected by Parkinson's.

Acknowledgments

The authors would like to express their gratitude to Department of Electrical and Electronic Engineering, Chittagong University of Engineering and Technology, Bangladesh for their continuous support and assistance throughout the completion of this study.

Abstract— **In-vivo observing of patient's heart mechanics by means of seismocardiography (SCG) was recently rediscovered and presented (Demonstrated). Most of the time, seismocardiography is recorded utilizing 2D or 3D accelerometers set on patient's sternum. This research represents the ability and performance development of a PVDF piezoelectric film transducer by placing them in multiple positions on the subject to record real time mechanical movement of the heart (seismocardiogram and heart sounds) and furthermore of the breath related thorax movement. Patient's ECG signal was also recorded simultaneously to give a time reference of the cardiovascular movement and better assessment of SCG signal acquisition. The piezoelectric sensor has been able to record respiratory signal, seismocardiography and heart sounds all along. These signals later have been processed on MATLAB by constructing simple digital filter. The seismocardiogram waveform gives off an impression of being reliant on the different periods of the respiratory cycle. The recorded signals of piezoelectric sensor show important data such as pulse rate, respiratory cycle (Inhale and exhale), timing of mechanical occasion inside the heart cycle, and so forth.**

Keywords— Seismocardiography (SCG), ECG, Piezoelectric sensor, Arduino UNO, MATLAB.

I. INTRODUCTION

The Seismocardiogram (SCG) was first observed in 1961 by Bozhenko, and later applied in clinical studies for the first time in 1991 by Salerno and Zanetti [1], [2]. Seismocardiography (SCG) is a non-obtrusive strategy in view of account the vibration produced by the mechanical constriction of the heart. The pressure waves created by the siphoning activity of the heart spread through the thorax and can be distinguish noninvasively at patient's external chest divider. Customarily, vibration is recorded by putting an accelerometer on the sternum of the patient while lying prostrate, in any case, vibrations can be really estimated everywhere throughout the thorax (particularly on the precordial territory) and for any position on body. Regardless of whether SCG is generally newer, the recording of body developments related with cardiovascular movement was proposed a lot before, with respect to the ballistocardiogram (BCG), Phonocardiogram, and many other methods [3], [4], [5], [6]. A reestablished enthusiasm for these procedures is because of the vast accessibility of ease sensor (for example MEMS accelerometers PVDF piezoelectric film) and the low price for manufacturing them. SCG signals contains highlights that compares to explicit occasions inside the heart cycle as mitral conclusion, aortic opening, and so on., specifically synchronous recording of SCG and echocardiogram permitted to perceive explicit occasions timing and a SCG wave classification was proposed . Besides, SCG timing can be identified with the essential heart sounds (S1 and S2) estimated on phonocardiogram (PCG) [7]. The SCG signal range cover the infrasonic range (for example frequencies underneath 25 Hz) in light of the fact that SCG is basically produced by the movement or mechanical activity of heart through the chest wall, while the capable of being heard PCG flag is for the most part created by the blood stream. As an option in contrast to the utilization of accelerometers, the capacity to record the developments of the chest through diverse sensors has been investigated but more importantly their position on the subject thorax has been deeply researched and examined. This investigation focused around the capacity to quantify precordial acceleration on patient's chest by using different piezoelectric sensor but mostly focused on thin polymer coated piezoelectric sensors also known as PVDF piezo sensor. Specifically, the examination aims to evaluate the capacity of exceptional wide-band sensors and detect appropriate position on human body for them to measure moderate respiratory developments, seismocardiogram and the heart sounds [8].

II. MATERIALS AND METHODS

A. Sensors and their Placement

Polyvinylidene fluoride (PVDF) polymeric film not only shows clear and strong piezo-electricity but also pyro- and ferroelectric properties and therefore it is used as a sensor or transducer material whose application is found in enormous sectors like biomedical devices, mechanical, metrological, etc. Here, we have used two PVDF sensor films (CAT-PFS0006 Vibration sensor) manufactured by TE Connectivity which is based on sensitive but robust PVDF piezo film. This particular sensor provides high sensitivity to vibration while minimizes external acoustic noise. It has a stress constant of $216\ N/m$.

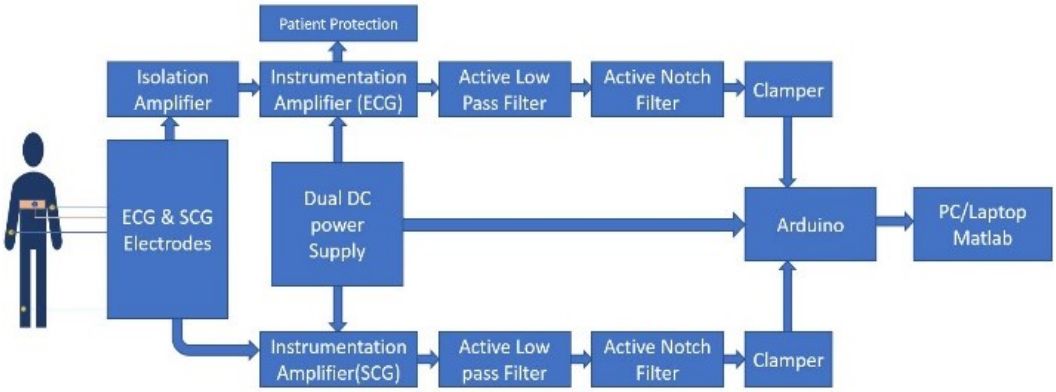

Fig. 1. Block Diagram of the proposed portable system for simultaneous acquisition of SCG and ECG signals.

This sensor can produce potential difference of $10\,mV - 100\,V$ depending on force and circuit impedance.

The sensor is mounted in a cantilever arrangement, allowing the sensing area to vibrate up and down. We have also added a small weight to the end of the sensor for getting greater sensitivity to lower frequencies. Cantilever arrangement will allow the piezo element to be deflected and this can be used to detect a vibrating object which is our subject chest when the element is flexed. Figure 1 shows the visual arrangement of cantilever system on a PVDF piezo sensor.

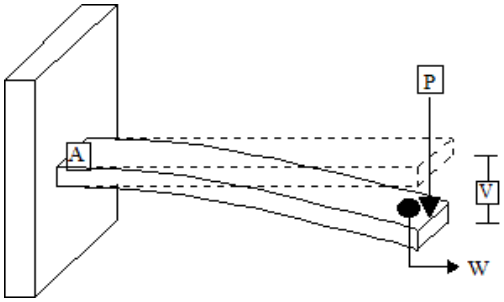

Fig. 2. Cantilever arrangement.

We have then attached the sensor on the subject's body using a belt for fixing the position. In usual cases the sensor is placed on middle of the sternum. We have moved the sensors couple of time in different places on sternum and found that putting the sensor on middle of the sternum may not give proper signals that contain all the valuable artifacts. Rather placing the sensors on the sternum it's better to set it on the left side of sternum which is known as *costal cartilage* has better chance of finding good signals. The weight on the sensor was attached in a way that it stayed touched with the subject's chest but no so tightly but tight enough to give vibration boost to the sensor. In this way the subject didn't need to stay laid on a surface but sit comfortably on a chair. The output voltage signal from the sensor was amplified by an instrumentation amplifier. At the same time ECG was also recorded for time and cardiac cycle reference. The amplified signal then passed through a low pass filter. Then another filter has utilized after the low pass filter known as notch filter. This process has some benefit over having just raw output signal. Pre-filtered signals have better visual on screen that has been recording and also has potential information whether the signal is really available or just random RF noise. Both ECG and SCG signal then being recorded by Arduino mega. The recorded signals then filtered out for extraction of potential information for the respiratory signal, SCG signal, and the heart sounds with the frequency bands of $0.05 - 1\,Hz$ for, $1 - 50\,Hz$, and $50 - 150\,Hz$ respectively [9], [10].

B. Hardware Implementation

Figure 2 shows the potable system design that has been used. The system is has the capability of running in battery power or using an AC-DC wall adapter. Both ECG and SCG circuitry contain Instrumentation amplifier, low pass filter(suppressing higher frequency noise) and notch filter (to minimize power line interference), voltage adder for shifting signal's negative portion to the positive side to make sure ADC can read analog input. Lastly Arduino mega is being used as a data acquisition device to simultaneously record both ECG and SCG and store it in Computer for further processing.

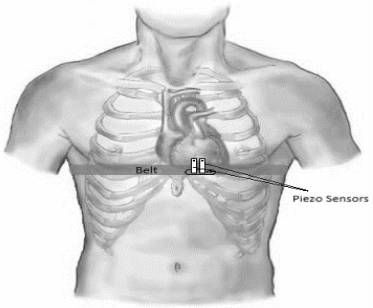

Fig. 3. Piezo sensor placement.

C. Instrumentation Amplifier

Two instrumentation amplifiers are used in this project to extract the ECG and SCG signal from subject. The instrumentation amplifiers used in this research are AD620 and INA121 for pre-amplifying ECG and SCG signals respectively [11] [12], [13]. Both amplifiers have high accuracy, but in comparison with AD620, INA 121 has bit more accuracy and advantages. INA121 has 4pA bias current while AD620 has 1nA. This gives the INA121 an impressive common mode noise cancelation about 106dB at G = 100. Both of this amplifier require an external resistor for setting the gain between 1 and 10,000. The gain of the amplifier (for AD620) can be found using the following formula:

$$A_v = 1 + \frac{49.4k\Omega}{R_{gain}} \qquad (1)$$

For INA121, the gain of the amplifier can be computed by using the formula given below:

$$A_v = 1 + \frac{50k\Omega}{R_{gain}} \qquad (2)$$

The following diagrams shows the schematic diagram of ECG and SCG circuit.

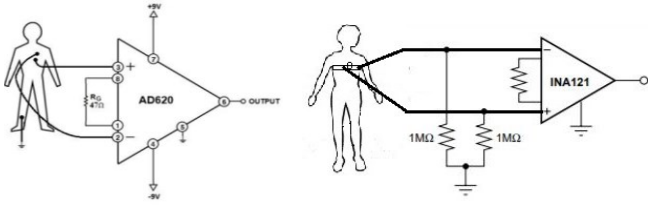

Fig. 4. Circuit Schematic used to extract the ECG (left) and SCG (right) signal from the chest.

D. *Isolation Amplifier*

Isolation amplifier, an op-amp based circuit which is also known as unity-gain amplifier, provides isolation of one side from the other side by optically transmitting data. This is done in such a way that the power is not wasted in any side of the circuit. The isolation amplifier has unity gain. For protection of the subject, an isolation amplifier is used in this research and isolated the subject form the circuit for safety purpose. Here Broadcom (HCPL-7800) general purpose isolation amplifier is used. The high CMR ability of this isolation amplifier gives the required precision and also stability. This IC design is based on fully differential circuit topology Functional diagram of the IC is given below.

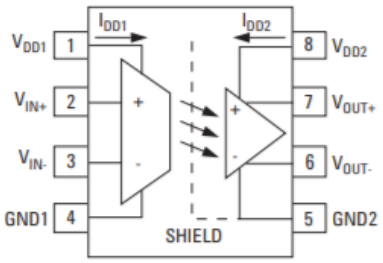

Fig. 5. Pin diagram of the isolation amplifier.

E. *Low-Pass Filter*

In this research two low pass filter was used to eliminate noise from the signals. One low pass filter is used for ECG and other one for SCG. A second order low pass filter having cutoff frequency of 80Hz is used for ECG to obtain decent frequency response. The cutoff frequency can be set much lower than 80Hz but there is a huge chance of losing high frequency components of the actual ECG signals. Cut off frequency of second order can be calculated by using the formula given below.

$$f_c = \frac{1}{2\sqrt{R_1 R_2 C_1 C_2}} \qquad (3)$$

A 10th order low pass filter used for SCG for getting clearer and better frequency response as SCG sensors tends to detect a lot of vibration from outer environment. The low pass filter used for SCG has 150Hz cut off frequency. Typical SCG signal contain three type of valuable information like Respiratory signal, Seismocardiography signal and Heart sound. To preserve all this information, we need to set the cutoff frequency to 150Hz. Higher filter order was used for making cutoff region as close as ideal response. Again, the cutoff frequency can be calculated by using the formula given below.

$$f_c = \frac{1}{2\sqrt{R_1 R_2 \ldots R_{10} \times C_1 C_2 \ldots C_{10}}} \qquad (4)$$

F. *Notch Filter*

To remove the 50Hz power line interference some sort of band rejection filter was needed. This research has used an active notch filter to reject the power line noise as the system has dual dc power system that draws power form main line. This band rejection filter is second order. Bandwidth was fixed at 2Hz and the quality factor Q was 25. Bainter topology was followed all along while designing such filter. The circuit schematic has given below.

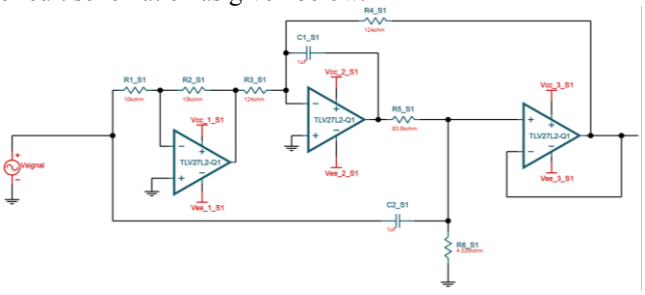

Fig. 6. Circuit schematic of the 50-Hz notch filter used in our system.

G. *Clamper*

ECG and SCG signals have both positive and negative cycle. However, Arduino can only sense the positive cycle of an analog input. In order to feed both positive and negative cycle of the signal, the level must be shifted to the positive side. To do that the system needs a clamper circuit which can be two types: active and passive clamper. In this research, an active clamper circuit was used. Three general purpose Op-Amps are used for construction of the clamper circuit. One for voltage buffer circuit and other two for adding the dc offset voltage to shift the level. The clamper circuit schematic is shown in figure 7.

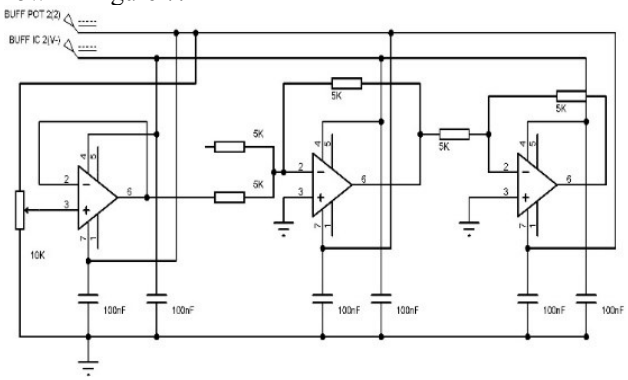

Fig. 7. Clamper circuit scematic used in the proposed system.

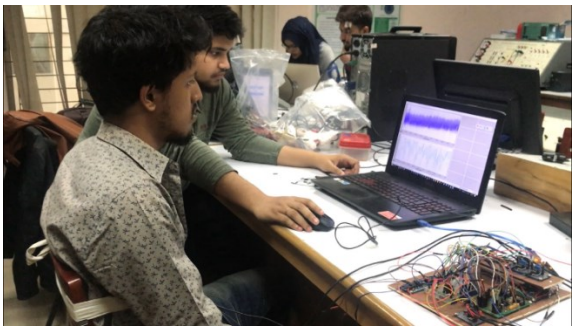
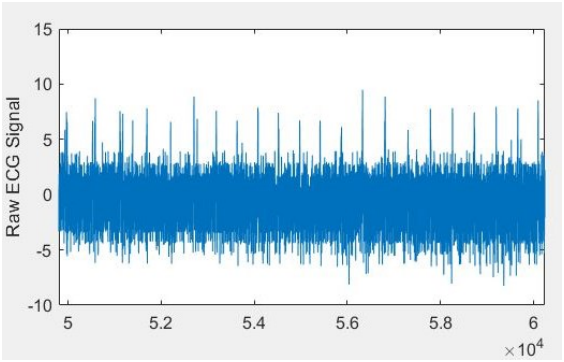
III. INTERFACING WITH PC

The ECG and SCG circuit that has been used for this research was interfaced with a Laptop/PC through an Arduino Mega. Signals from both ECG and SCG was fed to different analog pin of Arduino mega. Arduino was programed in such way that it can read both analog input data, perform ADC process and store the data in the PC/Laptop and repeat the whole processes as long as possible. Basically, this process runs in a continuous loop. This Arduino recording process was done by using telemetry viewer. 800 Hz sampling frequency was used in this process. Once the data was store in the PC/Laptop, further processing and analysis can be done. MATLAB is a resourceful and suitable software when it comes to process the raw signals and analyze them. Digital signal processing can be easily done to remove unwanted noise and interference as well as to analyze the signal characteristics to extract important features in terms of statistical parameters for diagnosis purpose.

The data from the Arduino was collected on pc/laptop using a special software name Telemetry Viewer. This software has lot of potential to work with such kind of miniature microcontroller device. The data was sent to PC/Laptop using serial communication at a baud rate of 115200. The resolution of the internal ADC of Arduino is 10-bit which means it can detect 2^{10} =1,024 different analog levels. Telemetry viewer software has capability to store large amount of data in a single shot. For experimental purpose every data that have been collected from different subject was length of 5 minutes and having 1040574 samples on average.





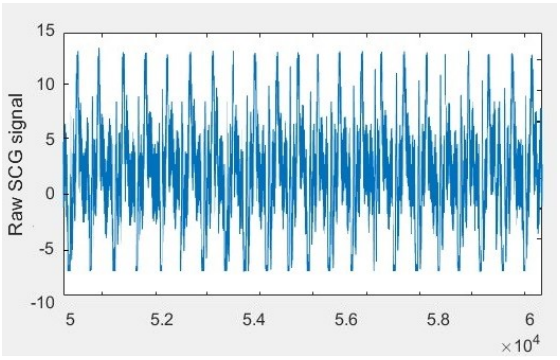


Fig. 8. Experimental set-up to record the simultaneous SCG and ECG.

IV. RESULTS

Figure 9 shows some raw signal recordings of ECG and SCG below.

(a)

(b)

Fig. 9. Recorded raw signals: ECG (a); PVDF piezo output (b).

Figure 10 represents the raw signals both ECG and SCG decomposed into the four frequency component which is being plotted subsequently. As for the respiration signal on the top trace has frequency band of $0.05 - 1Hz$. Second trace is SCG waveforms having a frequency band of $1 - 50Hz$. Third Trace is the ECG signal that has been taken as a time and cardiac cycle referance(R peak has been considred) [14]. Finally heart sound is plotted at the bottom of the figure and the frequency bad is $50 - 150Hz$. Some portion of the cleaned ECG and SCG signals are given below.

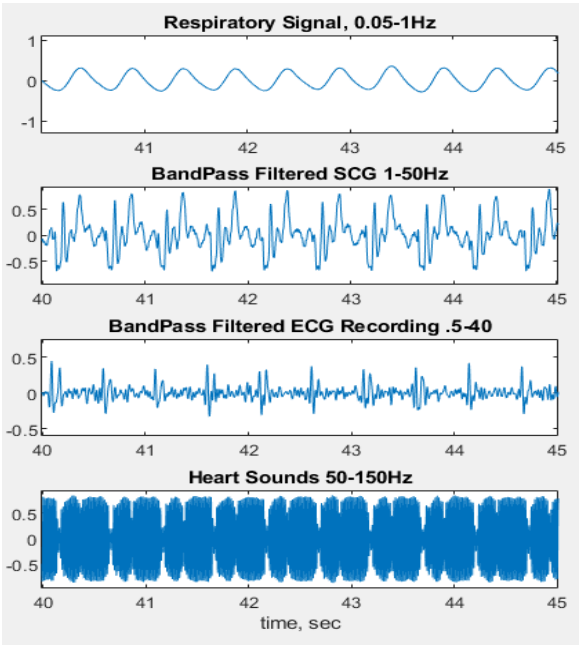

Fig. 10. The output signal of Piezo is decomposed in different frequency bands: from top to bottom: ECG; Respiration; SCG; and Heart Sounds respectively.

A portion of cleaned ECG and SCG signal are given in figure 11. The clean shows primary visual of SCG signal. To verify that the signal pattern has seismocardiographic wave the result is being compared with an accepted seismocardiographic wave form that has been represented by Amirtaha Taebi (2018) proposed that during each cardiac cycle, typical SCG contains actually two main events that can be called the first SCG (*SCG1*) and the second SCG (*SCG2*). Analyzing signals form this figure we found that it also contains these two events that have been identified. In the figure, the cardiac cycles are shown.

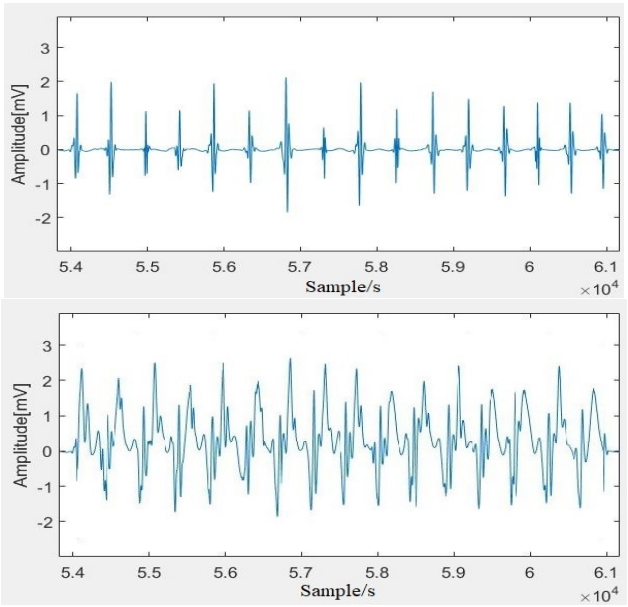

Fig. 11. Clean, recorded signals: ECG (top trace); SCG (lower trace).

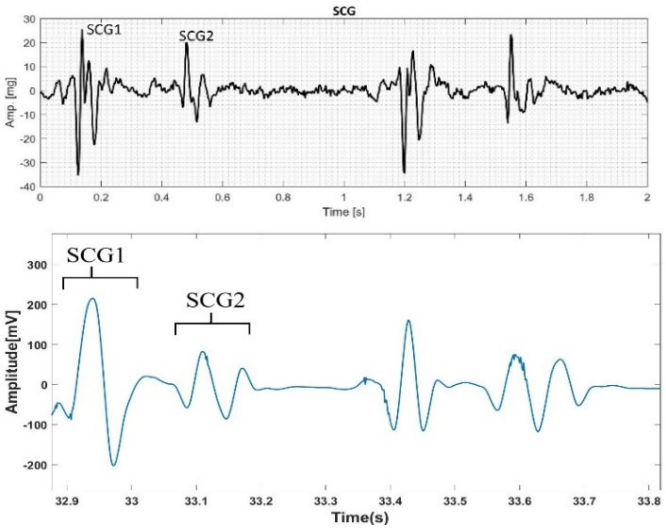
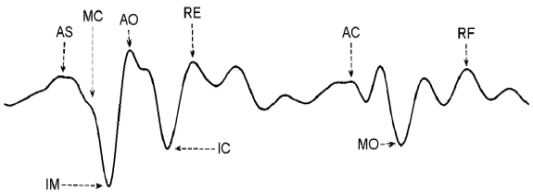
After analyzing the cardiac events a single waveform is taken from filtered signal for pointing out all the annotations that have been previously proposed and took as a reference signal to compare with filtered signal [15].





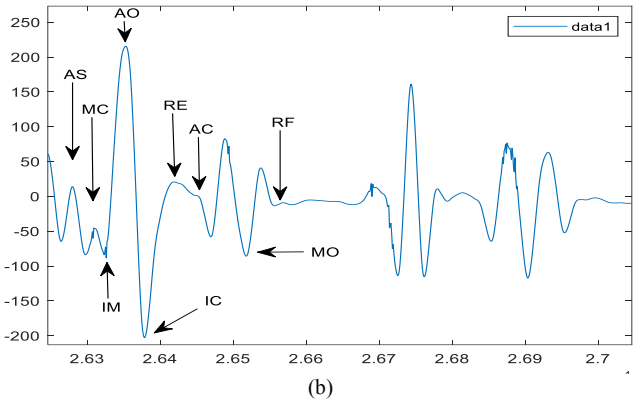


Fig. 11. SCG signal waveform shape comparison using standard annotations

Below the comparison result shows that all the annotations are present in the cleaned signal. Visual comparison is given in figure 12.

(a)

(b)

Fig. 12. Annotation of seismocardiographic signals using the annotation scheme proposed by Crow et al. (1994). (a) along with our recorded clean signal (b).

A synchronized averaging of the SCG waveforms identifying with individual heart cycles by considering the R-peak of ECG as time reference has been performed to compare the transient connection of ECG with SCG signal.

Figure 13 shows the results obtained from the operation of synchronized average made of 10 consecutive cardiac cycles. The average signals of ECG and SCG show the continuity of the annotations of the seismocardiographic signals. Comparing this average signal with another standard annotation scheme proposed by Anh Dinh (2011) also verify this research result [16]. Comparison of these two signals are given in figure 14.

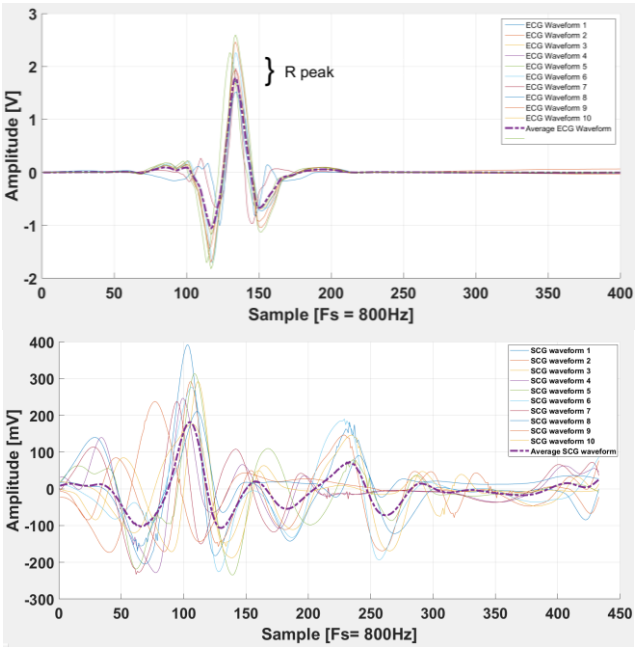

Fig. 13. Synchronized average of ECG (top) and SCG (bottom) signals over 10 cardiac cycles. The R-peak of ECG was considered as time reference. Average traces are highlighted in bold dashed lines.

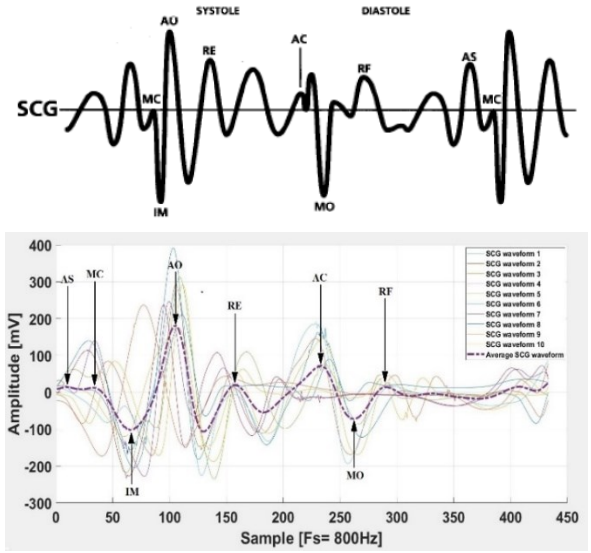

Fig. 14. Annotation of seismocardiographic signals using the annotation scheme proposed by Dinh (2011) et al. (Top trace) along with our recorded clean signal (Lower trace)

V. Conclusion

Two cardiovascular assessment systems were implemented in this research. The system was relatively simple and easy to handle. Current system implementation demonstrated the feasibility of SCG by using piezo sensors. SCG can be a great complementary analysis method along with ECG as it promises a lot handier information on heart's mechanical activity. Using two sensors instead of one promises more reliable and less noise full signal. Despite numerous studies in the field, there are still several limitations that must be addressed in the future work. These limitations include, but are not limited to:

- SCG variability (Age, Gender, thickness of chest wall Tissue)
- More realistic simulated SCG signals

***Abstract*—Day by day, the use of the internet is increasing; as a result, the way of communication through the internet is growing dramatically. So, speech signal compression is being a vital issue in the area of signal processing. There are many techniques used to compress a speech; such as Huffman coding, LZW coding, Arithmetic coding etc. These techniques convert a speech signal in such a way so that it takes very less memory and can be sent quickly over the internet than original data. From the point of view, this article introduces a novel speech coding method which use a set of binary combinations as needed to encode speech data. In this technique, the binary combinations are set to the probabilities of a speech signal where 0 and 1 will be assigned to the first two highest probabilities. The third, fourth, fifth, sixth, seventh and eighth probabilities are assigned by 00,01,10,11,000,001 and the process will continue until all probabilities are finished. Here, Average code length (ACL), compression ratio (CR), compressed file size and PSNR are considered to evaluate the performance of the proposed technique with the state of the art techniques. From the experimental outcomes, we have seen that the proposed method provides a better result than the state of the art procedures.**

Keywords: Speech compression, Huffman, LZW, Arithmetic, compression ratio, average bits length, speech signal to noise ratio.

I. Introduction

Speech can be expressed as the response of the vocal tract to one or more excitation signals. A statement is used to carry a message of human all over the world to each other [1,2]. A speech signal is stored in digital device or sent over the internet as a digital data. A large memory is required to store a massive amount of data in computer and a huge amount of time is needed to send the data over the internet. So, storing a speech signal in computer and transferring over the internet are two big challenges.

From the above points of view, Mahmut et al. proposed Huffman coding based speech signal compression procedure in [3]. In this algorithm, first of all, bandwidth diversity is analyzed for a quantized speech and then applied Huffman coding to compress the speech data. In the article [4,5], a data compression procedure using run-length-Huffman coding scheme is introduced. In the technique, a vector quantization is applied by a first stage lossy compression and then the lossy-compressed speech data are treated by a lossless compression at the second state. Finally, a run-length Huffman coding together with unary code is used to compress the data. Though Huffman coding based compression is good but it does not provide better results when the number of probabilities is large. Mustafa et al. proposed a new style speech data compression technique using Discrete Wavelet Transform (DWT) in [6,7] and shown that it provides better compression than the state of the art procedure. In [8,9], Sinha proposed a wavelet base speech compression procedure using median function thresholding. In the technique, a model is created using a generic compression scheme to represent a data in a compressed bitstream. It shows that 39.54% more compression is done than the state of the art technique and also demonstrates that it keeps 99.8184% signal energy. The article [10] discusses Discrete Cosine Transform (DCT), Wavelet Transform (WT) and Wavelet Packet Transform (WPT) based data compression and shows the comparison among them. Finally, it states that Wavelet Transform and Wavelet Packet Transform provides a better performance than Discrete Cosine Transform. Kinsner et al. propose a wavelet-based image compression procedure in [11,12]. Instead of the usual short-window ways, a wavelet-based time-frequency multi-resolution investigation is considered for compression. It shows that the wavelet-based technique can produce till 30 dB peak signal to noise ratio(PSNR) when 90% wavelet coefficients are truncated.

Hosny et al. proposes a speech data compression procedure using Wavelet Packet Decompositions (WPD) methods in this paper[13]. They take a speech data of Malayalam language for an experiment and used MSE, PSNR, NRMSE and MOS to calculate the performance of the proposed procedure. The author shows that the proposed procedure provides better quality than the state of the art techniques. In this technique, first of all, under a defined threshold level, all the high-frequency coefficients of the wavelet decomposition are killed using zero wavelet transform (ZWT). Secondly, the average zero wavelet transform (AZWT) is used to calculate the average of the estimated coefficients to achieve the goal of the first point. Finally, Lloyd's algorithm is used to quantize all the coefficients before encoding. The procedure provides

a better result in case of compression ratio than traditional discrete wavelet transform (DWT).

Speech coding techniques are two types; one is Lossy, and another one is Lossless. Kabir et al. discussed in the paper [14] that lossless procedure keeps the same copy of original signal without holding the entire bits of the message. As a result, the file encoded by lossless achieves smaller size than the original. Normally, the result of lossless compression is larger than lossy compression. Lossy audio compression method such as MPEG or MP3 may not be admissible for some use such as a stereo CD quality digital audio signal. Since, internet resources are limited, and everybody wants to transfer data quickly through it. Music distribution applications will offer highly compressed audio clips to the user for transferring.

Several techniques are introduced for digital audio signal compression in [15,16]. A popular one is based on sub-band coding . In sub-band coding, digital signals are partitioned into multiple sub-bands by multi-rate [U+FB01]lter-banks and then quantized according to the power of each sub-band signal. Another technique named Filter bank is used for audio coding using an iterative bit allocation. It was not useful to real-time communication directly because of the iterative bit allocation manner [17,18]. Because, the frequency energy distribution of audio signals is Non-uniform, so it is difficult to determine how to allocate the whole number of bits to each sub-band while reducing of quantization noise arising. Moving Picture Experts Group 1(MPEG-1) is a sub-band coding scheme, broadly used over the Internet or with digital devices [19-21]. There are some limitations of MPEG-1 given below though it provides an e[U+FB03]cient compression way [22].

- Bits are not allotted often for high-frequency sub-bands at a low bit-rate transmission.
- The quantizer of MPEG-1 Audio uses Fast Fourier transform of original signals to define how much bits be allotted. This process is not only computationally expensive but also not very suitable for real-time transmission.

Abdul Mawla et al. explained that in case of speech coding, Waveform is the most straightforward technique which reproduces a signal analysing the code sample-wise. Here the actual pattern of the speech signal is reconstructed without considering the characteristics of speech using the coding. A uniform 16-bits PCM and ADPCm are the well-known waveform can be investigated in both time and frequency domain[23]. In this paper, it has also been shown that if arithmetic coding is used then in case of decoding, the full code-word must be taken and an entire file could be corrupted for a single bit loss. Stearns et al. proposes an arithmetic coding based waveform compression in this paper[24]. In this technique, a loss linear prediction is applied to a digitized waveform to drop the compatible components. Finally, Arithmetic coding is applied to compress the data. A lossless coding has been proposed in the paper [25]. In this technique, a set of binary consecutive patters has been used to encode image data.

An innovative coding style based on binary sequence has been introduced for a lossless speech compression in this paper. In this technique, a set of binary combination are taken which are assigned to the probabilities of an original speech signal where the binary combination of the shortest length is assigned to the highest probability.The rest of this article has been made as follows. An existing algorithms have been discussed in section II. In section III, the proposed system has been introduced. Finally, The experimental results analysis and conclusion are shown in in section IV and V respectively.

II. Background study

There are many speech signal compression algorithm; Such as, Run-length coding, Huffman coding,LZW coding, Arithmetic coding etc. Huffman is a variable-length coding procedure used to compress data. A set of distinct symbols and their corresponding probabilities are used to encode a file which uses the tiniest code for the symbol containing the highest probabilities that provides a better reduction of the original signal.

In Huffman encoding scheme, all probabilities are sorted in descending order, and a tree is constructed using the possibilities. The two symbols with lowest probabilities from the list of probabilities are added, and the computed value is used as the root of the two's at each step. This process is continued until finished. When a tree is made, then it is traversed to encode the file. Huffman algorithm builds a binary coding tree in a greedy style, beginning with the leaves and again and again merges the two nodes with the least probabilities. A priority queue is used as the principal data structure to reserve the nodes. The pseudo code of Huffman Binary Coding looks below.

Input: Array P [1...n] of statistical probabilities. Output: Huffman coding tree with n leaves that has the shortest code length for P.

HuffmanCoding (P [1...n])

a) HT = Empty binary tree
b) Q = Priority queue of pairs (i, P[i]), i = 1...n, with P as the identification sign
c) foreach m = 1...n − 1
   i) a = extractMinP(Q)
   ii) b = extractMinP(Q)
   iii) P[n + m] = P[a] + P[b]
   iv) insertNode(HT, n + m) with children a, b
   v) insertRear(Q,(n + m, P[n + m]))
d) return HT

As an example, Huffman coding is demonstrated for eight symbols (S1, S2, S3, S4, S5, S6, S7 AND S8) and their probabilities (0.3, 0.2, 0.15, 0.15, 0.1, 0.07, 0.02 and 0.01) in Fig. 1. Average code length(ACL), Compression ratio(CR) for the same probabilities are given in the following TABLE I.

From the Table I, it is looking that Huffman coding uses 2.63 bits as an average code length which means it reduces 67.13%.

Shannon–Fano coding is slightly related to the Huffman coding. When the probabilities of data are negative powers of 2, then Huffman coding and Shannon-Fano produces the

Figure 1. Huffman encoding fashion

Table I
HUFFMAN CODING

S	P(i)	B2S	CLB2S(i)	P(i)*LBS(i)	CR
S1	0.3	00	2	0.6	6.0837
S2	0.2	01	2	0.4	
S3	0.15	010	3	0.45	
S4	0.15	110	3	0.45	
S5	0.1	011	3	0.3	
S6	0.07	0111	4	0.28

S8	0.01	11111	5	0.05	
				ACL=2.63	

best variable length codes. The main distinction between two procedures is that Huffman coding constructs a code tree from the bottom up while Shannon-Fano constructs its codes from top to bottom. Shannon determined that the concept of entropy from statistical mechanics play an essential role. Entropy estimates the degree of disorder in a mechanical system, which is related to the number of possible states of the system. There are some limitations of Shannon-Fano coding, one of them is, it does not guarantee optimal codes and another one is , two different codes for the same symbol can be generated. From the point of view, Huffman coding is better than Shannon-Fano coding.

III. RECOMMENDED SCHEME

The main interest of this article is speech data compression. A distinct method has been introduced for speech signal compression. In this technique, 0 and 1 are assigned to the first two highest probabilities. Two bits combinations (00, 01, 10, and 11) are assigned for the third, fourth, fifth and sixth greatest possibilities respectively. In the same manner, for next eight probabilities, three bits combinations (000, 001, 010, 011, 100, 101, 110, and 111) are assigned sequentially. The similar process is applied for next probabilities to encode data. The encoding and decoding procedure of the proposed coding are presented in Fig. 2.

Figure 2. Diagram of the Proposed encoding and decoding procedure

The encoding and decoding procedure of the proposed coding style are shown below: Finally send the encoded speech

Algorithm 1 Encoding Procedure

1) Read a speech signal and set i = 1
2) Calculates the probabilities (P) of the speech signal and sort them in descending order.
3) Calculate N = number of probabilities
4) Repeat step 5 to 6 until i $\leq$ N
5) Generate a binary combination X_i
6) Assign $P_i = X_i$
7) Scan the whole speech data and assign the binary combination.

data and the list of symbols where Symbol arrangements are arranged as the arrangement of the probabilities. The proposed

Algorithm 2 Decoding Procedure

1) Read the distinct symbols as the order were sent and assign 0,1, 00,01,10,11,000,001,010 code-word etc respectively.
2) Scan the whole encoded speech data and replaces each encoded code-word by the symbol where the encoded code-word matches with the code-word assigned to the symbol in the step 1.

coding scheme is given in Table-II using the same probabilities used in TABLE I.

Table II
PROPOSED CODING

Symbols	Probabilities	Proposed coding
S1	0.3	0
S2	0.2	1
S3	0.15	00
S4	0.15	01
S5	0.1	10
S6	0.07	11
S7	0.02	000
S8	0.01	001

Average code length(ACL) and compression ratio(CR) are demonstrated in Table III Using the same probabilities where CLB2S, and B2S indicate the code length of Proposed coding and Proposed coding respectively.

Table III
PROPOSED CODING

Symbols	P(i)	B2S	CLB2S(i)	P(i)*CLB2S(i)	CR
S1	0.3	0	1	0.3	10.4575
S2	0.2	1	1	0.2	
S3	0.15	00	2	0.3	
S4	0.15	01	2	0.3	
S5	0.1	10	2	0.2	
S6	0.07	11	2	0.14	
S7	0.02	000	3	0.06	
S8	0.01	001	3	0.03	
				ACL=1.53	

From the TABLE I and II, it looks that the Huffman coding uses 2.63 bits as an average code length and provides 6.0837 compression ratio where the proposed coding uses 1.53 bits as an average code length and provides 10.4575 compression ratio. It has been calculated that the proposed coding uses 41.8251% less memory than Huffman coding and provides 71.8938% more compression.

IV. RESULT ANALYSIS

Several human speech signals used as an input sample is exhibited in the following Fig. 3 where each symbols of the speech signals used in experiment hold 8, 16 bits space in memory. All speech signals are mono, sampled at 8 kHz. In this paper, compressed signal size, compression ratio (CR) and average code length (ACL) are used to analyze the results. Low average code length indicates the use of less memory whereas higher compression ratio (CR) is used to quantify the higher reduction. If a speech data contains n distinct symbols then average code length, compression ratio and peak signal to noise ratio (PSNR) are measured using the equation 1,2 and 3 respectively where P(i) is the probability of i^{th} symbol.

$$ACL = \sum_{i=1}^{n} P(i)L(i) \tag{1}$$

$$CR = \frac{Original\ Speech\ Data\ size}{Compressed\ Speech\ data\ size} \tag{2}$$

$$PSNR = 10xLog_{10}\frac{Max\ data\ of\ original\ signal}{\sqrt{\sum_{i=1}^{s}\frac{(OS-CS)^2}{M}}} \tag{3}$$

Where OS, CS and L(i) represent original signal and compressed signal and the code length of i^{th} probability and s is the total number of sample of the M sized speech signal. Based on the original signal size, compressed signal size, PSNR, ACL and CR, the comparison between the proposed coding and Huffman coding are given in TABLE IV. In TABLE IV, NC, HC and PC stand for no coding, Huffman coding and the proposed coding respectively.

Figure 3. Original Speech Signals

Table IV
THE PROPOSED AND HUFFMAN CODING COMPARISON

Sam	CM	OSS (KB)	CSS (KB)	PSNR	ACL	CR
1	NC	4.1953	4.1953	inf	16	1
	HC	4.1953	2.4989	inf	9.5303	1.6789
	PC	4.1953	1.3213	inf	5.0391	3.1752
2	NC	13.2735	13.2734	inf	16	1
	HC	13.2734	10.0719	inf	12.1408	1.3179
	PC	13.2734	6.0872	inf	7.3376	2.1806

We have applied Huffman coding, LZW coding, arithmetic coding and the proposed coding to seven different speech signals already shown in Fig. 3. After applying the state of the art techniques, we have got the results demonstrated in TABLE V.

From the TABLE V, for the first three speech samples, we look that Huffman coding uses 5.671, 11.725 and 9.530 bits; LZW coding uses 10.718, 12.618 and 1.051 and Arithmetic coding (AC) use 4.1374, 9.4335 and 8.4360 bits as average code length (ACL) whereas the proposed coding use 3.5, 5.5 and 5.039 bits for the same case. From this point of view, for the first three speech samples, we see that Huffman coding uses 38.282%, 53.092% and 47.125% ; LZW coding uses 67.345%, 56.411% and 54.402% and Arithmetic coding uses 15.398%, 41.7% and 40.268% more memory than the proposed procedure.

For the same three samples Huffman coding provides 2.822 1.365 and 1.679; LZW coding provides 1.529 1.106 and 1.448; Arithmetic coding estimates 3.867 1.696 and 1.897; and the

	Proposed	2.131	3.212	2.490

proposed coding provides 4.571 2.909 and 3.175 compression ratio.

Analyzing these compression ratio, we see that the proposed coding provides better results in case of both average code length and compression ratio.

After applying the proposed coding on the seven speech samples of different sizes, the signals have been reconstructed perfectly that has been shown in Fig. 4. We have also calculated peak signal to noise ratio (PSNR) of each signal and seen that it is inf for each signal. So, from the PSNR point of view, it can be stated that there is no any difference between the original signals and compressed signals.

A graphical representation of average code length of the seven speech signals have been demonstrated in Fig. 5 In this figure, four different bars have been shown for each speech sample where the bar to the left and right side represent Huffman coding and the proposed coding, and the middle-left and middle-right bar represent LZW and arithmetic coding. It is observing from the Fig. 5 that the bar for the proposed coding is smaller than that of Huffman, LZW and arithmetic coding which indicates that the suggested procedure use a few number of bits averagely than Huffman, LZW and Arithmetic coding.

On the other hand, the compression ratio of the same signals have been demonstrated in Fig. 6 and it looks that the proposed

Figure 4. Compressed speech signals

Figure 5. Comparison of average code length

coding provides a better compression than the state of the art techniques.The proposed coding reduces more than the state of the art procedures retaining the same quality. From the points mentioned above, it can be concluded that the proposed coding is one of the best lossless speech signal compression technique.

V. CONCLUSION

Speech compression is an important issue in the area of signal processing used to store in computer or send over the internet at high speed. The speech compression is obtained by representing each sample of digitized data by lesser number

Figure 6. Comparison of compression ratio

of bits. A speech signal compression system based on binary combination, a completely new coding style has been proposed in this article which work better than the state of the art techniques. The suggested strategy is illustrated to be more useful in speech signal compression than other techniques, such as Shannon-Fano Coding, Huffman Coding, LZW coding, Arithmetic coding etc. Moreover, the suggested algorithm needs less memory than others compression algorithm. This technique can be used to compress any data.

***Abstract*—The paper has observed that different environmental noises and sampling frequencies severely affect the performance of the MFCC and PLP based Bangla Isolated Word Recognition System. We have observed the effect of different types of environments on MFCC and PLP for 39 and 52 coefficients for 8 KHz, 16 KHz, 32 KHz, and 44.1 kHz sampling frequencies. From the experimental results, we have observed that for different sampling frequency both in noiseless and noisy medium PLP models detects better than MFCC except in CLASSROOM environment where different types of noise are present simultaneously.**

***Keywords*— MFCC, PLP, Clean and Noisy Environment, Different Sampling frequency, HMM, Bangla ASR.**

I. INTRODUCTION

Automatic speech recognition (ASR) technique helps a computer to identify the words spoken by a person into a microphone or telephone and converts it into a written text. For ASR research, a computer can perceive words with highest accuracy level which are intelligently spoken by any person and also independent of vocabulary size, noise, speaker characteristics, language or accent. Therefore, different types of feature extraction techniques have already been introduced. Among them, MFCC and PLP are most admired feature extraction techniques. That's why we have taken an effort to comprehend which feature helps us to get better detection rate for both noisy and noiseless medium at different sampling frequency for Bangla Corpus.

One of the most popular feature extraction techniques for speech analysis is MFCCs (Mel Frequency Cepstral Coefficients). This technique facilitates auditory processing and relatively fast to compute. It works based on the critical bandwidth frequency of human ears with filter spaced linearly at low frequency and logarithmic at high frequency. That's why it approximates the human system response more closely than any other system. But this system is not robust in the presence of additive noise and therefore it normalizes their values at speech recognition to minimize the influence of noise.

For this reason, another new technique based on the short-term spectrum for the analysis of speech is developed termed PLP which is the modified version of LPC. PLP use Bark scale instead of the Mel scale. It uses an all-pole model to smooth the modified power spectrum and then estimate the output cepstral coefficients. That's why in some particular conditions PLP outperforms MFCC.

Many researchers showed a great effort to find out the effects of different parameters [1] [4] on MFCC and PLP. Comparison among different feature extraction techniques [6] [9] [10] were also being observed using different language corpus. Furthermore, some documents exhibited us how different types of feature extraction techniques work [2] [3] [5] [7].

Therefore in this paper, we desired to observe the effects of different types of environment and sampling frequency for Bangla corpus language using delta, acceleration and third differential coefficients. Our experimental corpora have been made using isolated sentences. So, we used Hidden Markov Model (HMM) based on monophone model for our experiment as it is better for isolated voice recognition. HMM models have been built up using HTK toolkit and MATLAB software helped us to do this operation.

We have divided our paper into six parts including this introduction section. Part-II delineates the difference between PLP and MFCC. Part-III & Part-IV represents the experimental setup and the changes of configuration files that should have been done before creating a model. In Part-V we have tried to analyze the Result. And lastly, conclusion and future work are discussed in Part-VI.

II. PLP AND MFCC

MFCC is a robust, dynamic and most commonly used Feature Extraction Technique for speech which uses Mel-spaced filter banks. Therefore behave more likely to a human ear. The Mel filter bank is a series of a triangular bandpass filter. This scale behaves approximately linear below 1000 Hz and logarithmic for frequencies above 1000 Hz. The following formula is used to compute the Mel for a given frequency [3]

$$Mel(f) = 2595 \log_{10}(1 + \frac{f}{700})$$

The triangular filters are arranged in such a manner that the lower value of one filter is placed in the middle of the

previous filter and the higher value is placed within the center of the next filter.

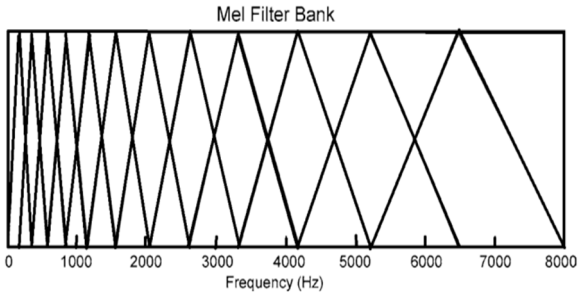

Fig. 1. Mel scale filter Bank

On the contrary, PLP is a new feature extraction technique which works on the psychophysics of human hearing. It is similar to linear predictive coding (LPC), except that the PLP technique also uses three concepts which are the critical-band spectral resolution, equal-loudness curve, and intensity- loudness power law [2].

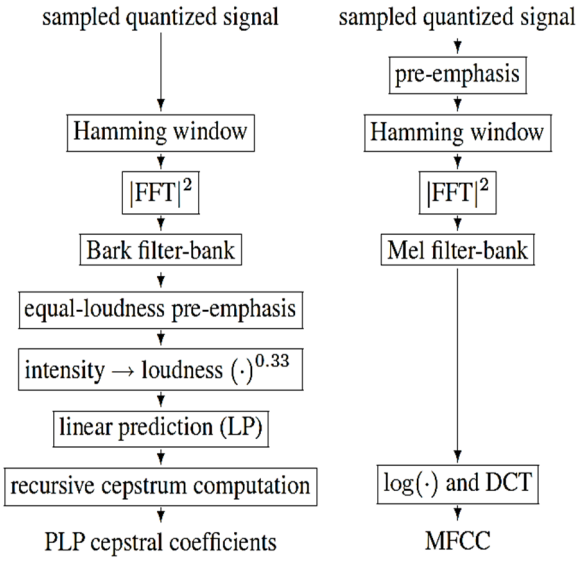

Fig. 2. The computation steps of PLP (left) and MFCC (right).

PLP uses Bark spaced filter bank instead of Mel scaled filter Bank where 1 Bark is approximately equal to 100 Mels. The Bark filter bank is a series of a trapezoidal shaped bandpass filter. This scale becomes more and more linear below 500 Hz and more or equal logarithmic above 500 Hz. The Bark for a particular frequency can be estimated using the equation given below,

$$Bark(f) = \frac{26.81f}{1660 + f} - 0.53$$

If result< 2, add 0.15*(2-result)

If result > 20.1 add 0.22*(result-20.1)

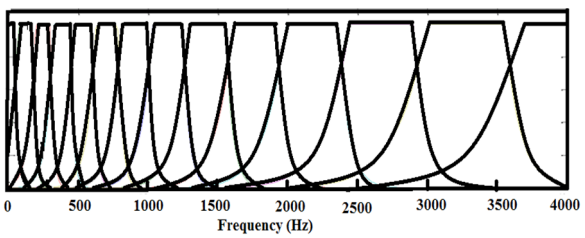

Fig. 3. Bark Filter Bank

PLP is a very low order. As it needs fewer coefficients, they are more efficient in terms of both storage and recognition complexity than most other spectral representation. They could show less sensitivity to speaker variation than most other spectral representation. Whereas MFCC is a fast and simplified model. But it's less sensitive in additional noise.

III. EXPERIMENTAL SETUP

For our experiment, we have taken isolated as well as some naturally spoken voices at 8KHz, 16KHz, 32KHz and 44.1KHz sampling frequency in both noiseless and noisy medium and then made some model using the monophone model which is actually fast and better for isolated voices. We have recorded voices in four different medium. They are (1) noiseless environment, (2) only AC noise present, (3) only FAN noise present and (4) CLASSROOM environment. We used both MFCC and PLP configurations for our experiments and tried to observe the effects of delta, acceleration, third differential and cepstral coefficients after appending them into the configuration for different situations. We have made four models for our experiments.

TABLE I. Experimental Models

Models	No. of voices for train corpus	Description
Model-1	800	In a clear medium, sentences are uttered by a number of male and female speakers for building the train corpus in different frequencies (8 KHz, 16 KHz, 32 KHz, and 44.1 KHz) and then use the base voices for the test.
Model-2	800	Sentences are uttered by a number of male and female speakers for building the train corpus in such a medium where the noise of **AC** is interrupting the sentences and then use the same base voices for the test.
Model-3	800	Sentences are uttered by a number of male and female speakers for building the train corpus in such a medium where the noise of **FAN** is interrupting the sentences and then use the same base voices for the test.
Model-4	800	Sentences are uttered by a number of male and female speakers for building the train corpus in a **CLASSROOM** where sentences are interrupted by several things and then use the same base voices for the test.

IV. CHANGE IN CONFIGURATION FILES

The main configuration files for MFCC and PLP are given in TABLE II.

TABLE II. Configuration Files

PLP	MFCC
SOURCEKIND = HAUDIO SOURCEFORMAT = HTK SOURCERATE = 226 TARGETKIND = PLP TARGETRATE = 100000.0 WINDOWSIZE = 250000.0 USEHAMMING = T PREEMCOEF = 0.97 NUMCHANS = 20 CEPLIFTER = 22 NUMCEPS = 12 USEPOWER = T LPCORDER = 12	SOURCEKIND=WAVEFORM SOURCEFORMAT = WAV SOURCERATE = 226 TARGETKIND = MFCC TARGETRATE = 100000.0 SAVECOMPRESSED = T SAVEWITHCRC = T WINDOWSIZE = 250000.0 USEHAMMING = T PREEMCOEF = 0.97 NUMCHANS = 26 CEPLIFTER = 22 NUMCEPS = 12 ENORMALISE = T

The qualifiers must append in the TARGETKIND for changing the model and number of coefficients. We have used the following TARGETKIND for our paper:

i. MFCC_D_A_0(39 coefficients) monophone HMM
ii. MFCC_D_A_0_T (52 coefficients) monophone HMM
iii. PLP_D_A_0(39 coefficients) monophone HMM
iv. PLP_D_A_0_T (52 coefficients) monophone HMM

SOURCERATE, TARGETRATE, and WINDOWSIZE require a floating point value in 100 ns units. In TABLE II. SOURCERATE = 226 indicates that the source is direct audio with sample period 22.6μs. Frequency is inversely proportional to period. So, frequency, in this case, is $\frac{1}{22.6\times10^{-6}}$ = 44.1 KHz.

TABLE III. SOURCERATE at each frequency

FREQUENCY (KHz)	SOURCECREATE
8	1250
16	625
32	312
44.1	226

V. RESULT ANALYSIS

Our database consists of 800 speech signals acquired during different sessions at the different sampling frequency. TABLE IV.toTABLE VII. shows the sentence detection rate (SDR) in percentage for Model-1. Here, 800 sentences are spoken by five male and three female in a noiseless medium which is used for making the train corpus. After that 100 voices have taken for the test purpose from the base voices.

TABLE IV. Model-1 at 8 KHz noiseless medium

M5	45	52	56	56
F1	93	96	97	96
F2	95	94	97	98

From TABLE IV.toTABLE VII.we can visualize the detection rate is quite good for each of the models at every sampling frequency except 44.1 KHz. At 44.1 KHz the detection rate is slightly poor than other frequencies. Also, we have observed that PLP detects better than MFCC in different sampling frequency in the noiseless medium. Moreover, PLP_D_A_0 & PLP_D_A_0_T both models gives better detection for 8 KHz sampling frequency. Otherwise, PLP_D_A_0 gives the highest detection at other sampling frequencies. In Fig. 4 the detection of PLP_D_A_0 in the noiseless medium is given.

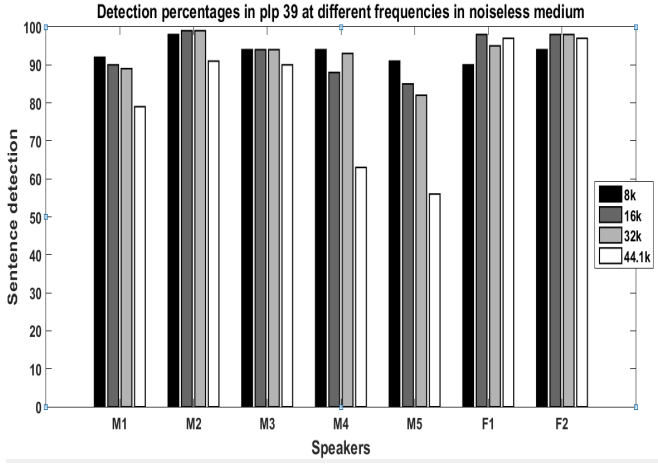

Fig. 4. PLP_D_A_0 at different frequencies in noiseless medium

Fig. 5 delineates the sentence detection rate (SDR) in percentage at 8 KHz sampling frequency in pure noiseless and AC, FAN &CLASSROOM noise based medium.

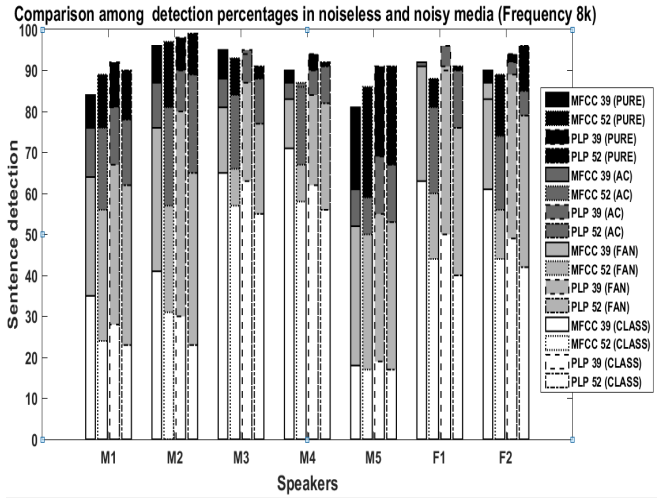

Fig. 5. Comparison between MFCC and PLP in a different medium at 8 kHz frequency

From Fig. 5 we can observe that the detection rate is highest in the noiseless medium and lowest in the CLASSROOM environment. We can also visualize that rarely AC noised medium's detection is approximately similar to the noiseless medium's detection rate.

Fig. 6 exhibits the sentence detection rate (SDR) in percentage at 16 KHz sampling frequency in pure noiseless and AC, FAN &CLASSROOM noise based medium.

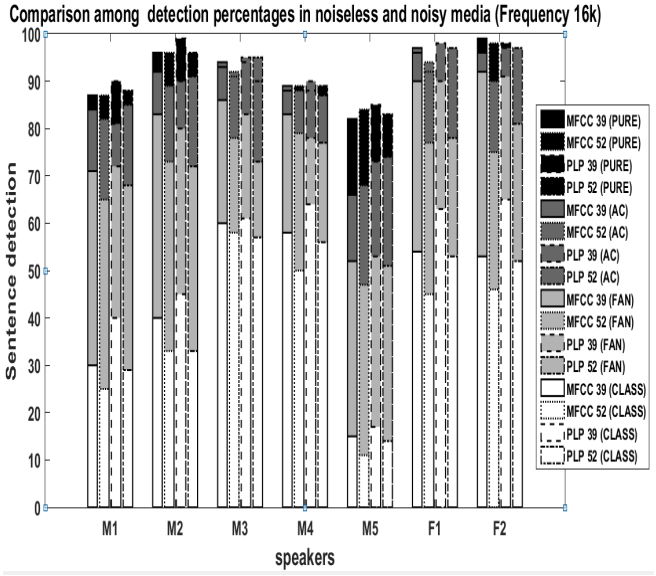

Fig. 6. Comparison between MFCC and PLP in a different medium at 16 kHz frequency

From Fig. 6 we can depict that again the detection rate is highest in the noiseless medium and lowest in the CLASSROOM environment. We can also exhibit that AC noised medium's detection is approximately similar to the noiseless medium's detection rate for a number of samples in many cases.

Fig. 7 & Fig. 8 visualize the sentence detection rate (SDR) in percentage at 32 KHz and 44.1 KHz sampling frequency in pure noiseless and AC, FAN & CLASSROOM noise based medium.

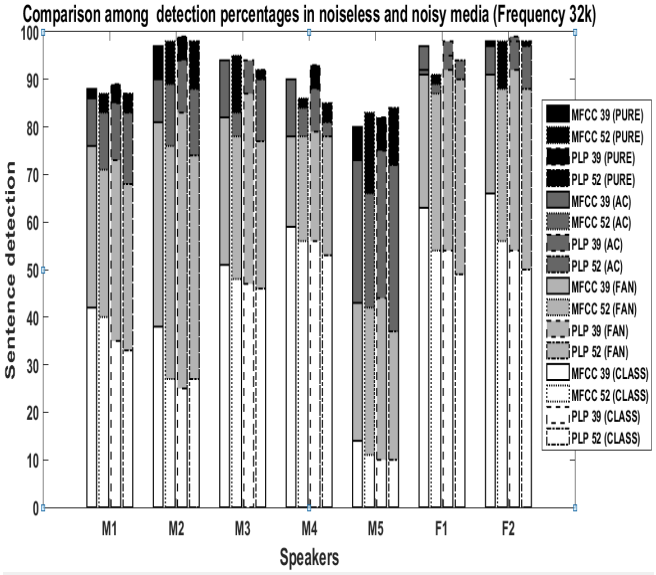

Fig. 7. Comparison between MFCC and PLP in a different medium at 32 kHz frequency

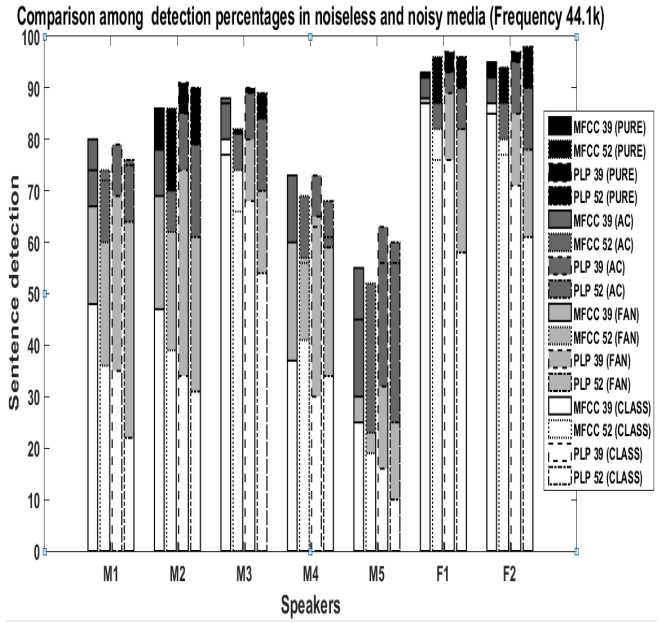

Fig. 8. Comparison between MFCC and PLP in a different medium at 44.1 KHz frequency

Fig. 7 & Fig. 8 show a similar pattern for highest and lowest detection as 8 KHz and 16 KHz. In some cases of 32 KHz, noiseless and AC noised medium detection are similar. But for 44.1 KHz frequency, the detection rate for both noiseless and AC noised medium are quite similar to each other and also less than other frequencies.

Furthermore, by observing Fig. 5 to Fig. 8 we can also identify that PLP_D_A_0 detects better than others in AC noised and FAN noised medium at different frequencies. But for CLASSROOM environment MFCC_D_A_0 outperforms all other models for each sampling frequency. In TABLE VIII.we can see the entire maximum detection rate per sample and detectors.

TABLE VIII. Maximum detection rate per sample in noisy medium at different frequencies

Medium	Frequency (KHz)	Maximum detector	M1	M2	M3	M4	M5	F1	F2
AC noise mixed	8	PLP_D_A_0	81	90	95	90	69	96	92
	16	PLP_D_A_0	81	90	95	90	73	98	97
	32	PLP_D_A_0	85	94	94	88	75	98	99
	44.1	PLP_D_A_0	79	85	89	83	70	93	95
FAN noise mixed	8	PLP_D_A_0	67	80	87	84	55	91	89
	16	PLP_D_A_0	72	80	83	78	53	90	91
	32	PLP_D_A_0	73	83	87	79	44	92	92
	44.1	PLP_D_A_0	69	74	80	67	32	89	85
CALSS ROOM	8	MFCC_D_A_0	35	41	65	71	18	63	61
	16	MFCC_D_A_0	88	86	92	88	54	97	97
	32	MFCC_D_A_0	42	38	51	59	14	63	66
	44.1	MFCC_D_A_0	48	47	80	37	25	87	87

From here we can say, though detection is poor in higher sampling frequency for noiseless or AC & Fan noised medium, it gives the highest detection in the CLASSROOM environment.

VI. CONCLUSION AND FUTURE WORKS

So, after all the experimental results we can come to this conclusion that PLP detects better than MFCC in noiseless as well as in noisy medium. But the detection rate varies depending on frequency. For higher frequency, this detection rate becomes poor however for a real-life noised medium like CLASSROOM it gives the highest detection. Though PLP outperforms MFCC in many noisy media, in a real environment like CLASSROOM, MFCC works better than PLP at any frequency. Moreover, 39 coefficient models dominate 52 coefficient models both in PLP and MFCC models. However, as we expected, in most of the cases, the detection rate of PLP is greater than MFCC. In this paper, we observed the effects of different environment and frequencies. So, in the future, we can enrich our database and can try to observe the effects of environment and frequencies using triphone model for naturally speaking a language.

***Abstract*—In this paper, Zeonex based hexagonal photonic crystal fiber (PCF) is proposed to obtain low confinement loss and moderate effective material loss (EML) at terahertz frequency. We use the finite element method (FEM) with a perfectly matched layer (PML) boundary condition to investigate the modal properties of the PCF. Simulated results demonstrate that this structure transfers signal in single mode condition. Besides, excessive low confinement loss of 6.73×10^{-11} dB/cm, and EML of 0.1491 dB/cm have obtained at an operating frequency of 0.55 THz. In this paper, other crucial guiding parameters such as air-core power fraction, effective area, bending loss, and dispersion of the fiber have also discussed. This terahertz fiber can be a good candidate for several applications in the terahertz regime.**

Keywords—Terahertz, single-mode fiber, effective material loss, confinement loss, bending loss.

I. INTRODUCTION

The wavelength of an electromagnetic wave within 3-0.003 mm (0.1-10 THz) is known as terahertz (THz) frequency band or sub-millimeter wave [1]. THz frequency band lies between the far end infrared radiation and microwave radiation. Because of its powerful applications, THz draws the attention of the researcher's eyes. THz radiation has been used in gas sensing, imaging in the medical sector, security, oral treatment, and microRNA based diagnostic [1]. THz radiation widely uses in biomedical applications like colon cancer diagnosis, ovarian cancer diagnosis, skin cancer detection, and to detect breast tumors. THz radiation has also used in the communication sector. It brings benefit in the local area networks (LAN) for the wireless communication system. Comparing with X-ray, terahertz radiation has some advantages in the case of its non-ionizing property.

Conventional THz waveguide suffers from high absorption loss and confinement loss which generally based on free-space line-of-sight (LOS) communications. Therefore, it is very challenging to design an effective waveguide that transmits the THz wave. To overcome these existing problems, the researchers have proposed different forms of waveguides. Metallic circular waveguides, slit waveguides, hollow metallic waveguides, bare metal wires are the example of metallic waveguide [1]. Metallic waveguides face trouble in the long-distance transmission due to ohmic loses, and dispersion. But in parallel-plate waveguides, there is no dispersion. However, they have diverge lose [1]. Researchers tried to demonstrate various types of polymer fibers such as Bragg fibers, dielectric plastic fibers [1], and porous core honeycomb fibers [1] to transmit THz signal effectively. In the THz regime, these Polymers fibers showed high birefringence. However, they face problems to transmit THz signal due to high absorption loss, low confinement of light, and the small possibility of fabrication. Polymers fibers have very high and positive dispersion too.

To overcome these shortcomings researchers demonstrate photonic crystal fiber (PCF). But solid core PCF has a high effective material loss (EML) in the THz frequency band. Porous-core PCFs show their uniqueness. They are capable of achieving low material loss and flexible in fabrication.

Many researchers keep their footprint to improve the transmission possibility in the THz frequency band. Reference [2] showed, polarization maintaining spiral PCF for THz transmission with the EML of 0.37 dB/cm and low confinement loss of 1.91×10^{-3} dB/cm at an operating frequency of 1 THz. This work also showed about 31% and 37% of the total power flows in the porous core for the core size of 410 μm. Atakaramians *et al.* proposed an asymmetrical sub-wavelength porous-core waveguide that exhibited an EML of >0.025 and confinement loss of 2.51 dB/cm at 0.65 THz using PMMA as the background material [3]. Islam *et al.* suggested a diamond-shaped porous-core which showed the dispersion of 2.92±0.55 ps/THz/cm and confinement loss about 0.1 dB/cm at an operating frequency of 0.70 THz [4]. They used Topas as their PCF's background material. Md. Hasan *et al.* [5] proposed a new type of THz fiber. This research work offered a cladding with square lattice and porous core which exhibited low and flattened dispersion from 0.65-1.05 THz. They showed their structure worked at single mode condition between a large frequencies ranges. Hasan *et al.* [6] demonstrated Topas based novel porous-core fiber with EML of 0.39 dB/cm and confinement loss of 1.17×10^{-3} dB/cm.

In this paper, using Zeonex as the background material, we design and characterize a hexagonal THz photonic crystal

fiber. In this paper, we use four rings of the air holes. In existing most of the work in this literature, several air rings were introduced. But using more air holes in the cladding region makes the structure large, and these decreases the fabrication possibility. This paper aim is to lower the confinement loss and increase power propagation into the core air-holes. We also analyze different significant modal parameters including dispersion, EML or material absorption loss, effective area, V-parameter, numerical aperture, FOM and bending loss.

II. Design Procedure

Fig. 1 shows the schematic structure of the proposed PCF with the expanded view of the porous core. In cladding region, four rings of the hexagonal structure are proposed which make the design compact and gives the adjustability of the fiber. Four rings are used because with the increasing of the air holes the refractive index of the cladding decreases. Many air holes in the cladding reduces the confinement loss. We have chosen hexagonal lattice in the cladding because it provides high confinement of light and easy to fabricate. In the hexagonal structure, identical air holes are used that provides fabrication flexibility. Moreover, air-filling fraction (AFF) can be better controlled which determines the loss on light confinement into the PCF.

In the cladding the hole-hole distance $\Lambda = D_{core}/0.43$. The diameter of the hexagonal cladding air hole is denoted by D and $D=0.42\times\Lambda$. For the simplicity the value of D is fixed for all the simulation. The value of D_{core} has been changed to calculate different parameters. In the core, rectangular shaped structure with eight horizontal line of air holes are chosen. In the rectangular line, air holes are missing after one another. We remove air holes because this gives better confinement of light through the core. In the upper and bellow of the rectangular core, we use two triangular shaped to maintain polarization. The diameter of core air hole is a_c. The distance from one line to another line is d_c. The value of $d_c = 0.30\times a_c$. The pitch of the core air hole is denoted by a_c, and the value of $a_c = 0.230\times D_{core}$ .The total diameter of the proposed PCF is taken $(4.1\times\Lambda + D)$. One of the important layers of PCF is perfectly matched layer (PML). PML is used to trim the computational period. In our proposed PCF the outer Layer is PML. In our design, PML is taken as 15% of the total fiber.

Polymethyle methacrylate (PMMA), Teflon, Topas, Zeonex are several polymers which were applied as a back-ground material for a THz waveguide and among of these polymers, Cyclic-Olefin copolymer (COC) commonly known as Topas used as the background material in most of the previous structures.

We consider Zeonex as the background material to design an effective THz waveguide. This material is selected due to its some advantages. It has a stable refractive index of 1.53 in THz region, low absorption of 0.14-0.30 cm^{-1} for 0.2-1.2 THz [7], insufficient water absorption of <0.1% [7], negligible moisture absorption [7]. Zeonex shows high transparency, sterilization, silicon oil-free, and drug compatibility. It also gives better stability in Heat exposures and humidity.

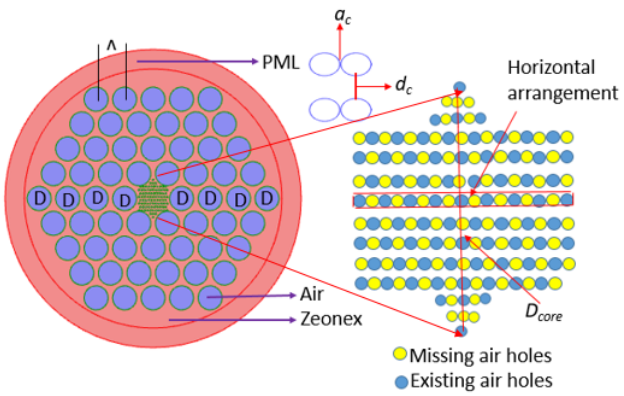

Fig. 1. Schematic sample of the proposed THz waveguide with a large view of core is shown beside.

III. Simulation Results And Discussion

To design and simulate this proposed PCF finite element method (FEM) based commercially available computer software package COMSOL v.4.2 has been used. Besides scattering boundary condition has been added to simulate and analysis the proposed structure. The complete mesh of our PCF contains 616 vertex elements, 4220 boundary elements and 0.05711 minimum element quality. To represent the complete structure 60378 elements are required.

The bulk absorption loss of Zeonex is 0.20 cm^{-1} that has been added in the simulation time. This structure has been analysed for different values of D_{core}. For D_{core}=300 µm, fundamental core mode power flow distribution of the proposed fiber is showed in Fig. 2 at 0.65 THz. This confirmed that the light is strongly confined in the centre of the proposed PCF.

Signal strength should be reduced due to modal distortion. Modal distortion is occurred by the PCF when the polarized light propagates in more than one mode. To avoid distortion, single mode fiber is desired. Using V-parameter the single mode condition of the proposed PCF can be validated. The characteristics of single mode can be measured by the following equation:

$$V = \frac{2\pi f}{c}\sqrt{n^2_{co} - n^2_{cl}} \le 2.405 \qquad (1)$$

When the fiber satisfies the above condition, a signal is transmitted by the fiber with zero interference.

In equation 1, n_{cl}= effective index of refraction for cladding, n_{co}= effective index of refraction for core, f= operating frequency. We calculate V-parameter for different operating frequency. Besides we also analysis the effect of D_{core} for a fixed frequency.

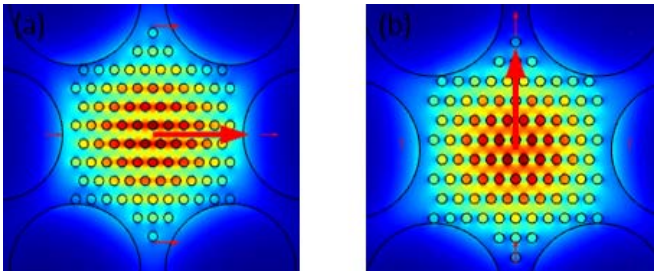

Fig. 2. Electric field distribution of the proposed fiber at 0.65 THz (a) x-polarized beam and (b) y-polarized beam.

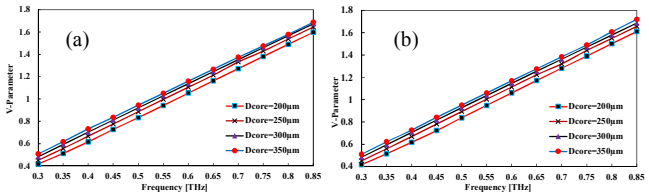

Fig. 3. V-parameter of the proposed waveguide as based on frequency for different D_{core} and n_{cl}=1 (a) x-polarized beam (b) y-polarized beam.

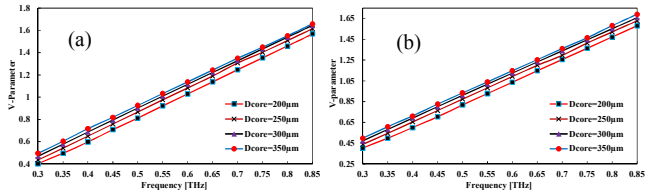

Fig. 4. V-parameter of the proposed waveguide as based on frequency for different D_{core} and n_{cl}=1.03 (a) x-polarized beam (b) y-polarized beam.

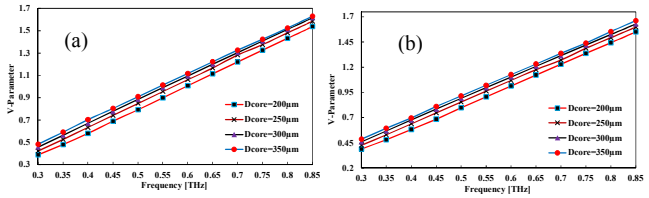

Fig. 5. V-parameter of the proposed waveguide as based on frequency for different D_{core} and n_{cl}=1.06. (a) x-polarized beam (b) y-polarized beam.

It can be reported that to design a waveguide, the cladding of the PCF primarily consists of a large sized air holes [3]. Besides the core consists of small sized air holes and bulk material respectively. Thus the effective index of refraction for the core should be found from the guided mode and the effective index of refraction for the cladding should be taken unity. From Fig. 3 it can be observed that V-parameter is an increasing function of frequency but it does not exceed the value 2.405. But the cladding region is not perfectly air in nature. Thus the effective index of refraction for cladding is unity is not true. Therefore, we calculate V-parameter for n_{cl}=1.03 and 1.06 respectively. From Fig. 3-5 it is clear that our proposed PCF propagates in single mode condition.

The background material of the fiber makes the signal weaker when light-wave travels through the PCF. Material absorption loss or EML is the main loss factor for a PCF. EML indicates that how much polarized light is absorbed by the background material. This important parameter is weighted by the following formula [2]:

$$\alpha_{eff} = \frac{(\varepsilon_0/\mu_0)^{(1/2)} \int_{A_{mat}} n\alpha_{mat} |E|^2 dA}{2\int_{ALL} S_z dA} cm^{-1} \quad (2)$$

Where, s_z=0.5(E×H*)z, s_z is the pointing vector.

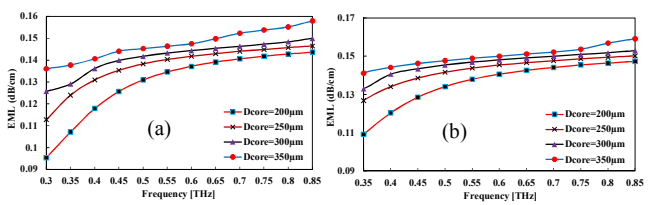

Fig. 6. EML of proposed waveguide as based on frequency for (a) x-polarized beam (b) y-polarized beam.

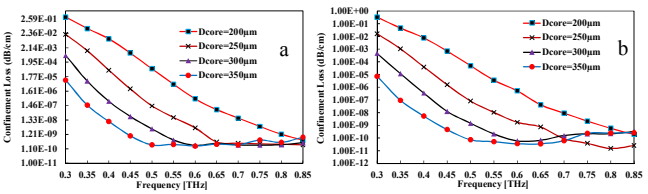

Fig. 7. Confinement loss of proposed waveguide as based on frequency for (a) x-polarized beam (b) y-polarized beam.

For a different value of D_{core}, Fig. 6 shows the EML as a function of operating frequency. From the figure, it can be seen that x-polarized mode and y- polarized mode exhibits approximate same amount of EML for a certain frequency. The calculated EML for the proposed structure are 0.1454 dB/cm and 0.1491 dB/cm for x-polarized and y-polarized modes, respectively for D_{core}=300 μm. The unit of cm^{-1} can also be expressed in terms of dB/cm by simply multiply it with 4.34. These values are found for a fixed frequency of 0.65 THz. By analyzing these value one can observe that x and y-modes absorb approximate same amount of the polarized light by the Zeonex.

Another loss factor of that proposed PCF is confinement loss. When polarized light propagates through the core some light is gripped by the nearest air holes. Confinement loss reduces the transmission possibility. The value of confinement loss should be kept low for efficient signal transmission. Due to the leaky nature of the modes confinement loss arises. It relies upon the arrangement of the air holes that used in the core and cladding. This important loss factor can be estimated by the following formula [2]:

$$\alpha_{cl} = 8.686 \times \frac{2\pi f}{c} \mathrm{Im}(n_{eff}) \times 10^{-2} \text{ dB/cm} \quad (3)$$

Where, f is the operating frequency, $Im(n_{eff})$ is the imaginary part of the effective index of refractive for fundamental core mode and c is the speed of light in vacuum space.

Fig. 7 shows the confinement loss of the proposed fiber for different D_{core} as a function of different frequency. α_{cl} is a decreasing function of D_{core} for both x-polarized and y-polarized modes. With the increase of D_{core} more light is fixedly confined in the core which gives surety that confinement loss is inversely proportional to D_{core}. From the Fig. 7 it is understood that x-polarized modes exhibits more loss than y-polarized modes. The calculated confinement loss of the proposed PCF for D_{core}=300 μm at 0.65 THz is found 2.71×10^{-10} dB/cm and 6.73×10^{-11} dB/cm for x-polarized and y-polarized modes, respectively. It can also be observed from the figure that for a fixed D_{core} confinement loss decreases with the increases of frequency. This happens because polarized light propagates through the higher refractive index region and that's why less light propagates through the cladding region at high frequency.

The power that is limited to different region of the PCF in the guided mode is called the fraction of power. Power fraction within the core in guided mode is a crucial parameter for characterizing the waveguide. But in many research paper power fraction was not calculated.

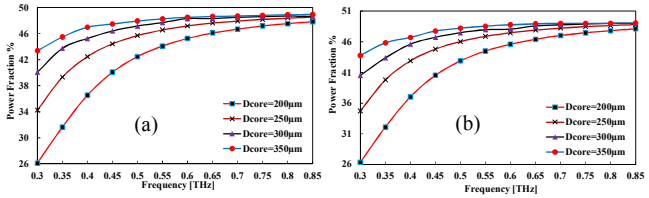

Fig. 8. Power fraction of proposed waveguide as based on frequency for (a) x-polarized beam (b) y-polarized beam.

Fraction of power in different region of the fiber can be computed by the following equation [2]:

$$Power\ fraction = \frac{\int_{X} S_Z dA}{\int_{ALL} S_Z dA} \tag{4}$$

In the numerator, the region of an interested area is denoted by X and in the denominator the total area of the fiber is denoted by ALL. For this proposed design power fraction of porous core is calculated as a function of operating frequency.

From Fig. 8 it can be observed that power fraction in the core region for the guided mood increases with the increases of the core diameter. Light is well confined in both x and y polarized beam. It is reported that the fraction of power for x-polarization and for y-polarization is 48.32% and 48.57% at D_{core}=300 μm and f=0.55 THz. It is also evident from the figure that the fraction of power through the core is same for a large bandwidth (0.60-0.85 THz).

For characterizing a PCF modal effective area is an important parameter. It indicates the actual area through which the polarized light propagates. In laser application and communication effective area plays a significant role. Higher values of effective area are required for laser application and lower values are required for communication. The area inside the core field of a fiber which is covered by the EM waves can be defined by the effective area and quantitatively measured by the following equation [6]:

$$A_{eff} = \frac{|\int I(r) r dr|^2}{|\int I^2(r) r dr|^2} \tag{5}$$

Where, I(r) =$|E_t|^2$=intensity distribution of the transverse electric field.

Modal effective area of the fundamental core mode as a function of frequency is shown in Fig. 8, for different values of D_{core}. From the Fig. 8 it can be observed that the effective area is reduced with the increase of the frequency. In this paper modal effective area is calculated for both x-polarized and y-polarized beam. From the figure it shown that the value of A_{eff} is 5.3×10^5 and 4.8×10^5 μm^2 for x and y-polarization.

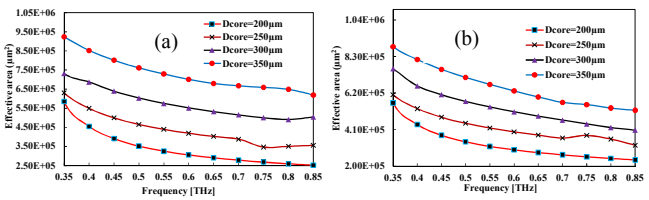

Fig. 9. Effective area of the proposed waveguide as based on frequency for (a) x-polarized beam (b) y-polarized beam.

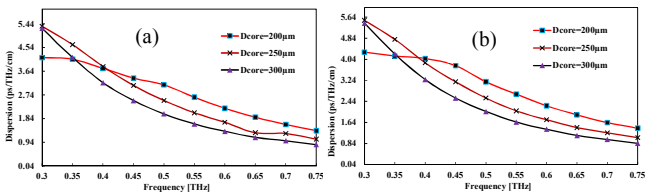

Fig. 10. Dispersion of proposed waveguide as based on frequency for (a) x-polarized beam (b) y-polarized beam.

Now we are interested to analysis another important parameter termed dispersion. It indicates that how much pulse is spreading when it propagates through the PCF. For characterizing an effective waveguide our principal target is to reduce the modal dispersion. From the waveguide structure, the modal dispersion creates. It also originates from the background material. Material dispersion and waveguide dispersion are two important dispersion factors for a PCF. But the novel material Zeonex has very low material dispersion in THz frequency band. Thus the effect of material dispersion is not considered for our calculation. Therefore, waveguide modal dispersion is observed for our proposed structure. Basically waveguide dispersion depends on the geometrical structure of the PCF and can be calculated by the following equation [2]:

$$\beta_2 = \frac{2}{c}\frac{dn_{eff}}{d\omega} + \frac{\omega}{c}\frac{d^2 n_{eff}}{d^2\omega} \text{ ps/THz/cm} \tag{9}$$

β_2 indicates modal waveguide dispersion. The 1st term of the equation is the 1st derivate of the effective refractive index in core mode with respect to the angular frequency. 2nd term of the equation is the 2nd derivative of the effective refractive index in core mode with respect to angular frequency, $\omega = 2\pi f$. Here f=operating frequency. From Fig. 9 it can be observed that the modal waveguide dispersion decreases with the increasing of the frequency. It can also be evident that the modal waveguide dispersion is low for both x and y-polarized modes at a certain frequency range.

For the overall assessment of a waveguide, the figure of merit (FOM) is an important guiding parameter. This crucial parameter can be quantified by the following equation [8]:

$$FOM = \frac{\alpha_{eff}}{A_{eff}} \tag{7}$$

From the equation it is clear that this parameter is simply found from the EML and Modal effective area. It is the ratio of normalized EML and effective area. Using this equation we calculate FOM for different values of D_{core}. The value of FOM is approximate same for both polarized beam. With the increasing of frequencies FOM is decreasing. For D_{core}=300um FOM is 3.66×10^{-6} um^{-2} for x polarized modes. Besides from the figure it is noted that the FOM is 3.26×10^{-6} um^{-2} for the same conditions.

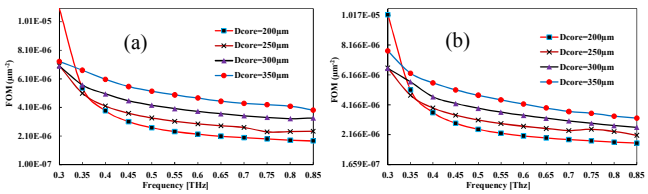

Fig. 11. FOM of proposed waveguide as based on frequency for (a) x-polarized beam (b) y-polarized beam.

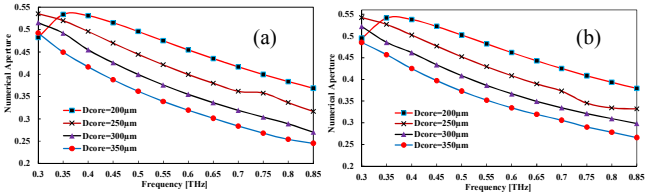

Fig. 12. NA of proposed waveguide as based on frequency for (a) x-polarized beam (b) y-polarized beam.

Light capturing capability is an important factor for a PCF. How much light is captured by a PCF can be defined by the Numerical aperture (NA). A large numerical aperture is needed for the broad sensing operation. High numerical aperture can be found when the effective refractive index difference between the core and cladding is made higher. If this happens more light will propagate through the core. This is the basic of PCF operation. We enhance NA by introducing new material Zeonex. We can calculate NA by using the following equation:

$$NA = \frac{1}{\sqrt{1+\frac{\pi A_{eff} f^2}{c^2}}} \quad (8)$$

From the Fig. 11 it can be seen that light capturing capability is high for our Proposed PCF. We analysis NA for different values of D_{core}. But For D_{core}=200 μm NA is high and for D_{core}=350 μm it is low.

For practical use, it is needed to bend the PCF. When a fiber is bent then the light propagates outer the core and it comes out in the cladding. If this happens light energy is absent at the ending point. Besides transmission length will be reduced. Thus for practical use calculation of bending loss is very important. Bending loss has a great impact on the guided mode power transfer by altering its architecture. Bending loss of a fiber can be not measured directly. Therefore bending loss has been calculated by using a simple easy-to-evaluate analytical method:

$$\alpha_{BL} = \frac{1}{8}\sqrt{\frac{2\pi}{3}}\frac{1}{A_{eff}}\frac{1}{\beta_{co}}F[\frac{2}{3}R\frac{(\beta^2_{co}-\beta^2_{cl})^{(3/2)}}{\beta^2_{co}}] \text{ cm}^{-1} \quad (10)$$

Hear, A_{eff}=modal effective area, R=bend radius, $F(x)=x^{-1/2}e^{-x}$. the proposed fiber has been observed for x polarized mode only. From Fig. 13 it is seen that bending loss decreases with the increasing of operating frequency.

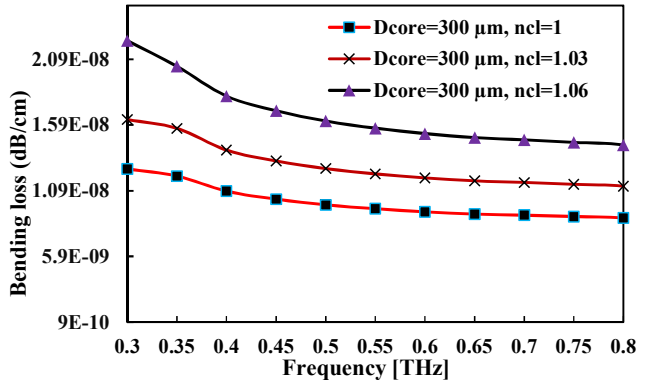

Fig. 13. Bending loss of the proposed waveguide as based on frequency.

For n_{cl}=1 the bending loss is low but for n_{cl}=1.06 the bending loss is high. So from the figure, it is clear that if the more holes are used in the cladding the bending loss will be low. If more air holes are used then the light will not propagates outer layer. Then it is possible to bend the fiber more. From the equation one can see that the unit of bending loss is cm^{-1}. But this term can also be expressed in dB/cm using conversion process. The bending loss is calculated for n_{cl}=1 is 9.13×10^{-9} dB/cm at 0.65 THz.

The performance parameters of the proposed fiber and existing works in the literature are tabulated Table. I.

TABLE I
CHARACTERISTICS COMPARISON

Ref.	Material	*f* (THz)	EML (dB/cm)	α_{cl} (dB/cm)	Power fraction %
[2]	Topas	1	0.37	1.91×10^{-3}	37
[3]	PMMA	0.65	>1.09	2.51	-
[4]	Topas	0.70	0.304	>0.1	-
[5]	Topas	0.75	0.169	0.087	34
[6]	Topas	1	0.39	1.17×10^{-3}	37
proposed	Zeonex	0.65	0.1491	6.7×10^{-11}	48.57

This table includes frequency, modal EML, confinement loss, and fraction of power through the core. From the Table. 1 it is clear that our proposed PCF shows less loss and high power propagates through the core in THz range.

It is crucial to address the manufacture possibility of our introduced waveguide. Several fabrication techniques have developed in recent years [2]. The proposed PCF consists of small-sized of air holes with two different dimensions. In cladding, we use a large air hole and in the core, we use a small air holes. Kiang *et al.* [9] demonstrated a new technique that gives fabrication freedom. This technique helps to demonstrate a complex structure practically. Capillary stacking technique mentioned in [10] used to fabricate circular air holes. The dimension of the air holes are adjusted freely in Sol-gel [2] technique.

IV. Conclusions

A Zeonex based THz waveguide is proposed and analysed that contains rectangular porous-core which offers high fraction of power through the core, low confinement loss, moderate EML and large effective area. Numerical investigation shows high fraction of power through the core over a wide frequency range of 0.60 to 0.85 THz. At 0.65 THz the power fraction of the proposed fiber is 48.57%. A flattened waveguide dispersion is obtained over a large frequency of 0.60 to 0.75 THz. Moreover, moderate EML of 0.1491 dB/cm and about 4.8×10^5 μm^2 modal effective area can be obtained for the optimum design parameters. This proposed structure acts as a single mode fiber, therefore it can be used for long distance transmission.

***Abstract*— In this paper, we proposed EEG based epileptic seizure detection where statistical bandwidth of intrinsic mode functions (IMFs) are used. EEG signals are decomposed into IMFs through the implementation of Empirical Mode Decomposition. These IMFs are turned into analytical functions by means of Hilbert transformation. Euclidean value of Amplitude and Frequency Modulated Bandwidths are calculated from these analytic functions. Finally, the statistical distribution bandwidth of these different IMFs is considered as a feature. The classification was done by means of Support Vector Machine (SVM) with the Gaussian kernel. For training purpose, 75% of the data is utilized. Finally, 89.6% accuracy was gained for the remaining 25% test data in the SVM classifier.**

Keywords*— Empirical Mode Decomposition (EMD), Intrinsic Mode Functions (IMF), Hilbert Transform, Support Vector Machine.

I. INTRODUCTION

Epilepsy is the 4th common neurological disorder where the neurons start firing abnormally which finally leads to the formation of seizure. It is mostly found in people at the age of 7-15 and 65-70 and about 1 % of the worldwide population is affected by this disease [1]. Eighty percent of epileptic seizure severity can be minimized if identified properly. Bangladesh, being a developing country, the portion of epileptic patients are increasing because of the inadequacy of accurate diagnosis technique.

EEG is a low-frequency signal which can give info about epileptic seizure inside the brain. Manual detection of epilepsy can be time-consuming and inaccurate. That's why computerized EEG based automatic epilepsy detection is necessary. EEG based epilepsy detection has mainly two steps: feature extraction and classification. Many renowned EEG feature extraction processes have been used worldwide. Fourier transform of EEG signal is commonly used for classification of seizure given the signal is stationary [2]. But there persists a window problem where an exchange between time and frequency resolution has to be considered. But as EEG is a non-stationary signal, methods like the smoothed pseudo-Wigner-Ville distribution is used which depends on time-frequency domain [3]. But the method uses a genetic algorithm which fails to define an optimum solution. Consequently, DWT extracted line length features for sub-band decomposition of EEG signals are used to detect epileptic seizure [4]. But its computational expense increases in case of fine analysis. Recently, many nonlinear methods are used for parameter extraction to analyze EEG signals. Among these parameters, both complexity and spectrum analysis features have been popular for the identification of epileptic EEG signals [5]. As an EEG signal is non-linear signal and the total data span is too short [10]. That's why it is quite challenging to accurately extract feature for seizure EEG signal detection. For solving these problems in a non-linear signal, EMD based feature extraction technique was first introduced by Huang et al. in 1996 [10]. Moreover, it has been revealed that the conventional EMD method has lesser computational complexity and more classification accuracy compared to multivariate EMD [7]. So nowadays it has become a state of art of field of signal processing. A non-stationary EEG signal is broken into some predictable numbers of intrinsic mode functions (IMF) and a residue by this process. The IMFs are a form of data expansion for the decomposition. Their orthogonality cannot be predicted but their scale is predetermined. So IMFs have to be transformed into analytic signals. Because the analytic functions provide time-dependent instantaneous frequency (IF) and amplitude functions which has valuable information on the local properties of the signal. Hilbert Transform is applied on these IMFs to determine analytic function. Hilbert Transform is a useful tool in situations where frequency fluctuates with time, namely non-stationary signals. It is considered much more efficient than FFT in case of non-stationary signals [6]. So after the conversion into the analytic signals, these instantaneous frequency functions and amplitude functions are calculated. Because they are needed for extracting the amplitude modulated (AM) and frequency modulated (FM) bandwidths. These AM and FM bandwidths were taken as features for seizure detection erstwhile [13]. But these two features show little promise for accurate detection. Therefore, our proposal is the calculation of their Euclidean total bandwidth. Because the variation among these bandwidths for different IMF carries important information for epileptic seizure detection. So, the mean and variance of the total Euclidean bandwidth of all IMFs of a single EEG signal are considered as corresponding features. This distribution of bandwidth feature is supposed to increase the ability to detect epileptic seizure.

Finally, for data classification, Different types of classifier like the random forest, Naïve bias, neural network, SVM, KNN are used. But SVM has global minima that avoid overfitting and require less number of data for data training. SVM has broadly used in classification, regression and feature reduction task. In most cases, it is used for classification purpose for supervised learning. It mainly maximizes the margin to create a hyperplane with the help of kernel function. Kernels are used to transform the feature vectors from input space to kernel space for linearly non-separable datasets. Different types of kernels are used like linear, polynomial, sigmoid and Gaussian in SVM classifier. The linear kernel is used for a huge number of input features. For a few feature space, the Gaussian kernel has performed better. That's why SVM classifier with Gaussian kernel is used for classification purpose.

The above mention EEG seizure detection algorithm is used EMD based feature extraction and SVM with Gaussian kernel. Autoregressive Coefficient Extraction with the SVM classifier based system has an accuracy of 54.77%. Using Power Estimation with FFT and Fisher Discriminant Analysis based system accuracy is 72.4%. Spectral Density Estimation based Bayes Quadratic Classifier has increased the rate to 81.5%. The Stock-well transform feature extraction process associated with KNN classifier produced 84% accuracy rate. For signal energy estimation using DWT and feature classification using SVM picked up the accuracy rate to 84.73% [14]. Compared to these five methods, our EMD feature based proposed method needs less computation complexity and it performs better in small noise signal and SVM classifier required less amount of data and less time required for data training. So it is expected SVM classifier with EMD feature extraction will perform better.

As from here, section II will describe our method of feature extraction and classification process. The result and discussion of this method are given in section III. Finally, we have a conclusion for the paper in section IV.

II. Methodology

A. Dataset:

EEG dataset which is used in this paper is publicly available online [8]. The dataset is divided into five categories which are symbolized by Z, O, N, F, and S. There are 100 single channel EEG signals in each set which makes a total data of 500. Each one has 23.6s duration and a sampling rate of 173.61 Hz. A bandpass filter was used where the band frequency was approximately 0.50~40 Hz (12 dB/oct). The subset N, F and S were recorded intracranially and subset Z and O were recorded extracranially from five healthy volunteers with eyes opened and closed respectively.

The EEG signals from subset F and N are taken from five patients when they were in epilepsy-free intervals. The subset S contains epileptic activity which is mainly complex partial seizure. So here signals from subset Z, O, N and F are considered as non-seizure class and signals from subset S is considered as seizure class. Fig.1 shows one signal from each category.

.

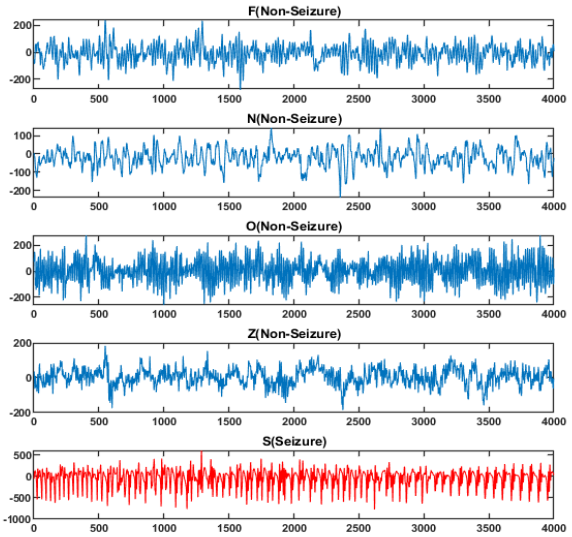

Fig. 1. EEG signal of five sets.

B. IMF Generation using EMD:

The hypothesis that a number of different simple intrinsic

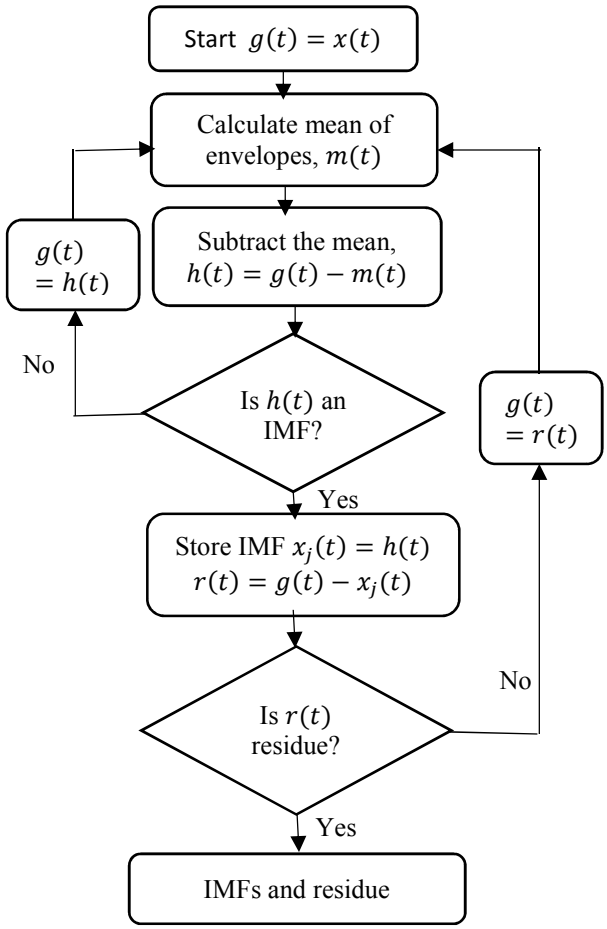

Fig. 2. Flow Diagram of the EMD Algorithm.

modes of oscillations forms a non-stationary and non-linear time series established the EMD method. It is a form of time domain analysis like Fourier transform and Wavelet decomposition. The objective of the method is to empirically recognize these intrinsic modes by their local characteristics of time scales in the data, and then decompose the data into IMF accordingly [9]. EMD filters out the time-frequency information of the IMF. It converts a signal $x(t)$ into its constituent IMFs maintaining two conditions: 1) An IMF has one single extremum between two subsequent zero crossings. 2) An IMF has a mean value of zero.

EMD algorithm: The following algorithm shows the process for extracting the IMF from the EEG signal. (Fig. 2). It decomposes a signal $x(t)$ into a set of IMF $c_n(t)$ and one residue r(t). So the signal can be represented as their summation like the equation below

$$x(t) = \sum_1^n c_n(t) + r(t) \quad (1)$$

After EMD is executed one signal is represented by several IMFs and one residue as shown in Fig. 3.

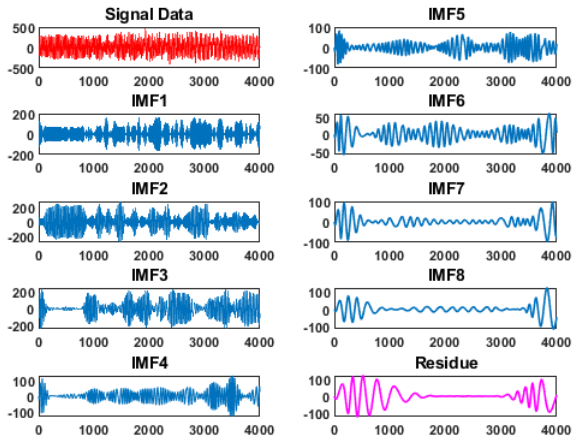

Fig. 3. Empirical Mode Decomposition of a Seizure Data Sample.

C. IMF to Analytic signal conversion:

An analytic signal contains complex functions which have no negative valued frequency component. The Hilbert Transform is done to obtain analytic functions from IMFs [10]. It instructs every Fourier function component to make a phase shift of 90°. Hilbert transform is the convolution of any real function with another function called Cauchy kernel which is, $h(t) = 1/\pi t$.
The final function is given by $c_H(t)$

$$c_H(t) = c(t) * h(t) \quad (2)$$

Every real IMF can be converted to an analytic signal using the equation below

$$z(t) = c(t) + jc_H(t) \quad (3)$$

Equation (3) can be written as

$$z(t) = A(t)e^{j\varphi(t)} \quad (4)$$

The amplitude $A(t)$ and instantaneous phase $\varphi(t)$ of the analytic signal can be determined using equations as follows

$$A(t) = \sqrt{c^2(t) + c_H^2(t)} \quad (5)$$

$$\varphi(t) = \arctan[\frac{c_H(t)}{c(t)}] \quad (6)$$

The instantaneous frequency (IF) of the analytic signals can be gained from equation (6) as given below

$$\omega(t) = \frac{d\varphi(t)}{dt} \quad (7)$$

$A(t)$ and $\omega(t)$ of a random signal from 'S' category is shown in Fig. 4.

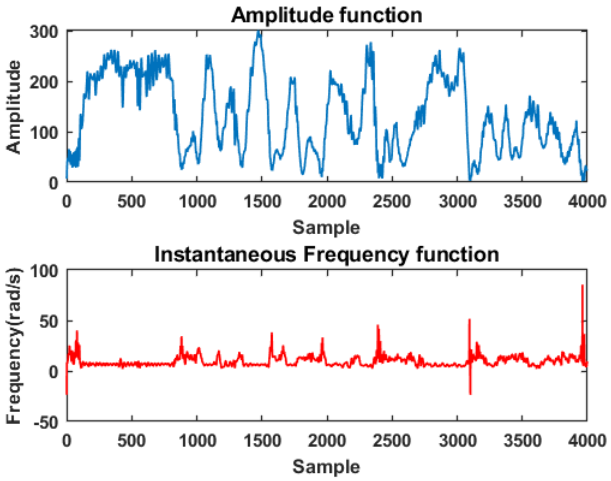

Fig. 4. Amplitude and Instantaneous Frequency (IF) function of the analytic signal.

D. Acquisition of Total Bandwidth:

The bandwidth is a measure of the spread in frequencies for the total time of the signal. Amplitude change and mean frequency of a signal can deviate the frequency range. But the bandwidth cannot precisely determine for which parameter the range changes in a signal. In order to determine, for which parameter the range changes, two different quantities are measured in this case namely amplitude modulated bandwidth (B_{AM}) and frequency modulated bandwidth (B_{FM}) [11]. Each analytic signal contains different energy levels for different working conditions. The energy of a signal z(t) is determined by the eq. (8)

$$E = \int |z(t)|^2 dt \quad (8)$$

If $Z(\omega)$ denotes Fourier transform of signal $z(t)$ then the center frequency of the analytic functions $z(t)$ is given by

$$< \omega >= \frac{1}{E} \int \omega |Z(\omega)|^2 d\omega \quad (9)$$

The amplitude modulated and frequency modulated bandwidth can be given as

$$B_{AM}^2 = \frac{1}{E}\int(\frac{dA(t)}{dt})^2 dt \quad (10)$$

$$B_{FM}^2 = \frac{1}{E}\int\left(\frac{d\varphi(t)}{dt} - < \omega >\right)^2 A^2(t)dt \quad (11)$$

The Euclidean value of Amplitude and Frequency modulated bandwidths in any analytic IMF $z(t)$ is given by

$$B = \sqrt{B_{AM}^2 + B_{FM}^2} \quad (12)$$

The Euclidean total bandwidths of different IMF for a random signal from each category is shown in Fig. 5.

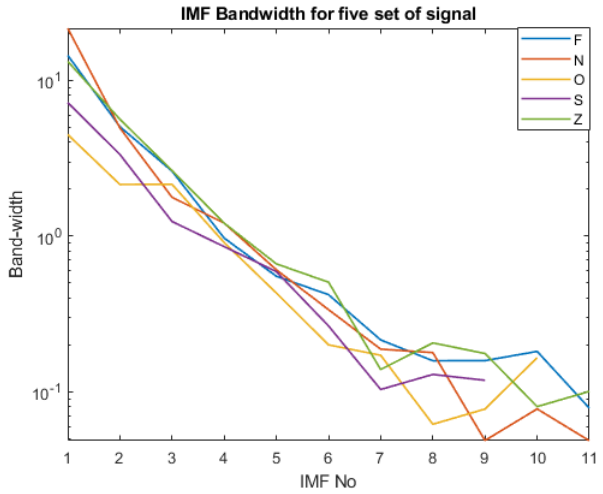

Fig. 5. IMF Bandwidth of sample signal from five datasets.

The mean and variance of all IMF Euclidean Bandwidth are taken as features. These two feature value is diverse for the Seizure and non-Seizure of EEG signal which is visualized in Fig. 6.

E. Data classifiers:

For non-linear classification, Support vector machine, K-nearest Neighbor and Neural Network are mainly used. But SVM is the most popular technique for solving the pattern recognition problem. SVM classifier mainly creates the decision boundary using N-dimensional separating hyperplane that maximizes the margin and identifying the different classes of data [12]. For non-linear classification, kernels are used. It calculates similarities between observations in the feature space of training set example that's why the selection of proper kernel function is important. Gaussian Kernel is the most popular kernel choice in SVM. The Gaussian kernel can be defined as [13]

$$K(x, x_i) = e^{\frac{-|x-x_i|^2}{2\alpha^2}} \quad (13)$$

Where α controls the width of the RBF function.

So The SVM classifier decision function is

$$f(x) = sign[\sum_{i=1}^{N} \alpha_i y_i k(x, x_i) + b\,] \quad (14)$$

Where α_i is called Lagrangian multiplier and b is is called bias.

The mean and variance of bandwidth are given as input feature in the Support Vector Machine. For training purpose, 75% data of each subset as a total of 375 data is used as training of SVM classifier. Fig. 6 shows a scattered plot of two different data classes- seizure and non-seizure.

After training the data, we have found an SVM trained network. Then 125 test data (25% of overall data) is tested in these SVM networks for predicting these unknown class. From Fig. 7 show the test data scattered plot and for proper visualization, SVM decision boundary is also included where the purple colored region is seizure and green is non-seizure. It shows maximum test data is contained in there following proper region.

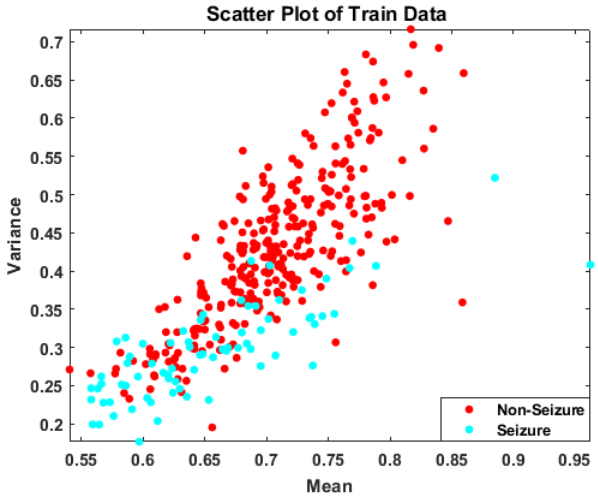

Fig. 6. Scattered plot of train data

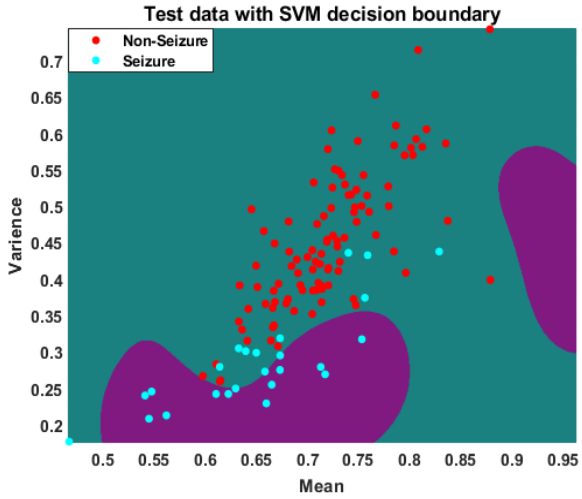

Fig.7. SVM decision boundary with test data.

III. Results and Discussion

A very important part of research work is to calculate the success rate and accuracy. Without it, the research might not have any value. So we are going to discuss the validity and accuracy of our work.

After extracting the features from IMFs of each signal we can see that the seizure signal features are less in magnitude than the non-seizure signal features. So thus we can effectively understand that our features can actually be useful in SVM.

The outcomes of our SVM classifier are represented in the confusion matrix given below. A confusion matrix is a tool for the execution of measurement of any classification algorithm which uses a specific table layout for supervised learning. The rows and columns are represented by output and target class respectively. Where diagonal element shows the number and percentage of the correctly classified and while off-diagonal term represents the misclassified observations. The cell at the last row of the last column shows the overall accuracy

$$ACC = \frac{TP+TN}{TP+TN+FP+FN} \times 100 \quad (15)$$

Where the total number of correctly detected positive events is indicated by *TP,* the number of correctly detected negative events indicated by *TN,* the total number of incorrectly detected positive events is indicated by *FP* and the number of incorrectly detected negative events indicated by *FN*.

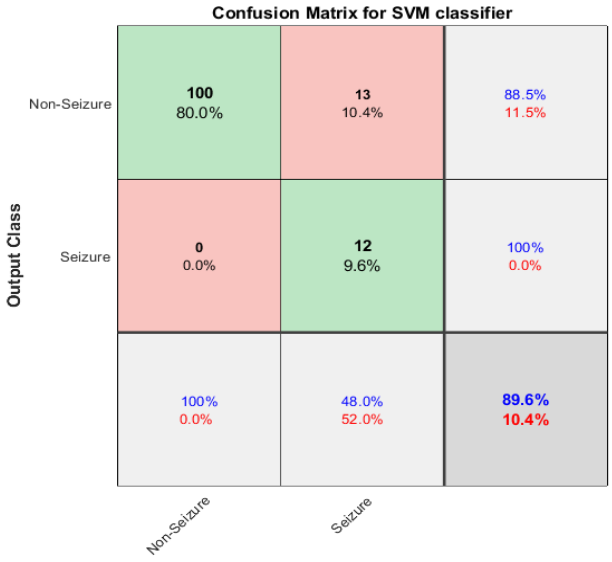

Fig. 8. Confusion matrix for SVM Classifier

Fig. 8 shows the confusion matrix for SVM. We can understand from the confusion matrixes 89.6%. From the confusion matrix, we can easily understand that our feature extraction method has better gross output than other methods [14].

IV. Conclusion

The most used techniques for EEG signal classification require much more sampled data and a wide number of extracted features. We have used EMD for feature extraction of EEG signals and identified the seizure class using support vector machine. The bandwidth features are used for classification in this method. This technique resulted in better accuracy and proficiency. The suggested method is used because of its lower requirement of data and features associated with a strong classifier.

The recommended method may be applied for examination and sorting of other non-stationary signals. Future guidelines of this research include real-time classification using the convolutional neural network (CNN) and the increment of classification accuracy using Wavelet kernel function.

***Abstract*—Electrocardiogram (ECG) is a graphical representation of the electrical activity of the heart which is obtained by placing various electrodes on some specific positions of the body surface of the subject. Abnormalities in the ECG signal of a patient may indicate cardiac diseases that need to be attended by physicians on an urgent basis. Hence, it is necessary to detect an abnormal ECG for the betterment of the patient. Such a method to classify ECG signals whether they are normal or abnormal is developed in this work. Angina, Bundle Branch Block, Cardiomyopathy Heart Failure, Dysrhythmia, Myocardial Hypertrophy, Myocardial Infarction, Myocarditis, Valvular Heart Disease: all these cardiac conditions have been classified as abnormal ECG signal in our work. First, statistical features like skewness, kurtosis, standard deviation of detail and approximation coefficients of the Daubechies wavelet (db10) of order 5 for a number of abnormal and normal ECG signals obtained in the feature extraction stage. Secondly, Support Vector Machine (SVM) was used for classification which was trained by the features extracted in the first stage. Finally, the accuracy, sensitivity, specificity of this method was checked by testing the SVM with 36 signals obtained from MIT-BIH Normal Sinus Rhythm Database and 36 signals from PTB Diagnostic ECG Database which yielded an accuracy, sensitivity, specificity 98.61%, 97.37%, 97.22% respectively.**

Keywords—ECG, SVM, sinus, signals, coefficients, features, sensitivity, accuracy, specificity.

I. INTRODUCTION

ECG signals are obtained through non-invasive measure which shows the electrical activity of the heart. Abnormalities in ECG signal can indicate a case of medical emergency which is needed to be taken care of immediately as it will deteriorate the condition of the patient under observation. So, it is necessary to develop a method to classify the ECG signals based on their shapes and characteristics whether they indicate a cardiac disease or not [1].

Cardiovascular (CVD) and circulatory diseases are the leading causes of death in the world. In 2013 there were more than 54 million deaths (95% uncertainty interval [UI], 53.6–56.3 million) globally and 32% of these deaths i.e. 17 million (95% UI, 16.5–18.1 million), were due to CVD. Most of these CVD deaths were found to be due to either ischemic heart disease (IHD) or cerebrovascular disease [2]. Hence, a system is required that will aid the physicians and diagnosticians in detecting an abnormal ECG signal which resembles a troubled cardiac condition. Such a system is developed through our proposed method. For this method to work with high efficacy it is necessary to train it with a stiff database that will enable it to separate a normal ECG from an abnormal ECG [3]. This method is fast, easy and very accurate. The entire work was carried out in MATLAB. Databases used to train the system are:

- The Physikalisch-Technische Bundesanstalt (PTB) Diagnostic ECG Database
- The MIT-BIH Normal Sinus Rhythm Databaseprovided.

The MIT-BIH Normal Sinus Rhythm Database includes 18 long-term ECG recordings of subjects referred to the Arrhythmia Laboratory at Boston's Beth Israel Hospital (now the Beth Israel Deaconess Medical Center). Subjects included in this database did not have any significant arrhythmias; they include 5 men, aged 26 to 45, and 13 women, aged 20 to 50. The Physikalisch-Technische Bundesanstalt (PTB) Diagnostic ECG Datababase contains a total of 549 records from 290 subjects (age range 17-87, mean age 57.2; 209 men, mean age 55.5, and 81 women, mean age 61.6; ages were not recorded for 1 female and 14 male subjects).

In patient monitoring system, one of the parameters monitored constantly is the Electrocardiogram of the patient [4]. It is because if there is anything wrong with the patient's heart, the ECG will convey this information. The purpose of this work is to classify a number of cardiac diseases as abnormal ECGs using a fast and congenial method with high efficacy. Such a method is needed if any kind of abnormality appears in the ECG, even a layman can understand it and notify the doctors.

Various papers have been published regarding detection of abnormal ECG signals. These techniques primarily use various classifiers to classify the abnormal and normal ECG signals. Some of them also use morphological features to classify the ECG. The methods also vary in extracting features though there are some similarities too. A strategy dependent on LabVIEW (Laboratory Virtual Instrument Engineering workbench) is described in [2]. The purpose of LabVIEW signal processing tools is to denoise the signal before applying the developed algorithm for feature extraction. Primary feature that has been extracted are the R-peaks which is done using Haar wavelet. For low resolution signals daubechies (db6) wavelets are used. Other features used in this paper are Q wave width, T wave, P wave, R wave width, ST segment and T wave amplitude and duration. Frontal plane axis scoring pattern is applied for abnormality detection. In this study Tachycardia, Bradycardia, Left Ventricular Hypertrophy, Right Ventricular Hypertrophy and

Myocardial Infarction have been considered as abnormal ECG. A wavelet coherence (WTC) technique has been proposed in [3] for ECG signal analysis. WTC is used to calculate the similarity between two waveforms in frequency domain. Parameters extracted from WTC function is used as the features of the ECG signal. These features are optimized using Bat algorithm. The Levenberg Marquardt Neural Network (LVNN) classifier is used to classify the optimized features. Atrial fibrillation is classified as abnormal disease in this work. The method proposed in [4] focuses on classifying Myocardial Infarction as an abnormal ECG signal. In the feature extraction stage, first segmentation of each ECG beat is performed. Then every ECG beat is processed by flexible analytic wavelet transform (FAWT) for decomposing into subband signals. Using these subband signals Sample entropy (SEnt) is computed. Finally in the classification stage, the sample entropy values are fed to a number of classifiers, namely: J48 decision tree, Random Forest (RF), Least-Squares Support Vector Machine (LS-SVM) and Back Propagation Neural Network (BPNN). An approach based on Cross Wavelet Transform (XWT) is described in [5]. One way to measure similarity between two waveforms in time-domain is to find out the cross-correlation between the signals. The Morlet wavelet is the mother wavelet used in this paper. When XWT is applied to a pair of data, it gives us Wavelet Cross Spectrum (WCS) and Wavelet Coherence (WCOH). If the characteristics or pattern of the ECGs are different, then WCS and WCOH would demonstrate distinguishing characteristics over two specific locales or regions R1 and R2, where R1 stands for the QRS complex and R2 stands for the T wave region. After marking discernible dissimilarities of the signals in R1 and R2, ECGs are classified as normal and abnormal based on an appropriate threshold.

The method for abnormality detection developed in this work is different from the works mentioned in this section in such a way that it does not require any kind of preprocessing stage. It's a straightforward method which begins by taking the detail and approximation coefficients from daubechies wavelet of order 10 of the normal and abnormal ECGs. The reason behind choosing 'db10' wavelets is Daubechies wavelets family provides better performance for detecting discontinuities and transients with respect to continuous wavelet transform**.** Then the features, skewness, kurtosis, standard deviations are extracted for training the SVM. Skewness, kurtosis, standard deviation was chosen as features over other statistical features because they can determine the extent of asymmetry of the distribution, measure it's tailedness and determine its dispersion. Finally, the abnormal ECG signals are detected.

We have organized the paper as follows: Section II describes the complete methodologies for the proposed method. Section III includes the results and discussion of this work and gives a comparison between other works and our proposed method. Finally, Section IV comes with the conclusion of the whole work done in this paper.

II. METHODOLOGY

For doing observation and analysis we have used ECG records which were collected from the MIT-BIH Normal Sinus Rhythm Database and were made available through Physionet. The range of age of the subjects is 20-42 years.

A. Workflow of proposed feature extraction method

A simplified workflow of the feature extraction method is described in this section. First a certain number of signals are selected for the purpose of feature extraction and training the Support Vector Machine (SVM). First, only the normal ECG signals are selected. Then they are decomposed into 5 levels using Daubechies wavelets of order 10 ('db10') and their detail coefficients and approximation coefficients are extracted. Skewness, Kurtosis, Standard Deviation of these coefficients are calculated which are the desired features [7]. Using these features, a feature matrix and a group matrix are created. A numerical value of '1' is used in the group matrix for normal ECGs. Same procedure is followed from the beginning for abnormal ECGs with the exception being that a numerical value of '0' is used in the group matrix [8]. A block diagram for the workflow is given in Figure 1.

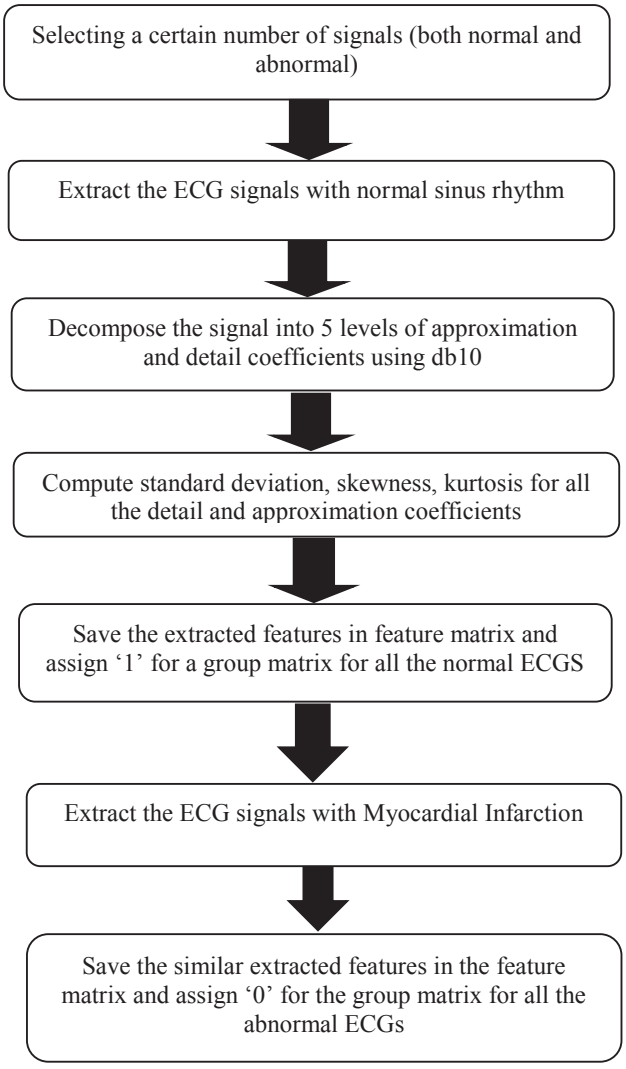

Figure 1: Workflow of proposed feature extraction method

B. Feature Extraction Method

Here, the proposed method for feature extraction has been described. All the steps for wavelet decomposition using Daubechies wavelets of order 10 i.e. 'db10' into 5 levels have been described step-by-step [9]. The relevant MATLAB waveforms are also given. Creation of feature matrix and group matrix for training the Support Vector Machine is explained too [10].

First, a number of ECG signals are selected for feature extraction which includes both normal and abnormal ECG. All the files are in mat extension format. Each file representing abnormal (diseased) ECG contains signals from 15 different leads whereas each file for normal ECG contains signals from 2 different leads. The steps of feature extraction are described below:

1. Seven (7) .mat files (105 ECG signals) with Myocardial Infarction i.e. abnormal ECG and seven (7) .mat files (14 ECG signals) having normal sinus rhythm are selected for feature extraction.

2. There are 2 dimensions (ECG signals) in a for a recording of normal sinus rhythm. Hence, in the beginning of feature extraction, the first dimension is extracted in Figure 2.

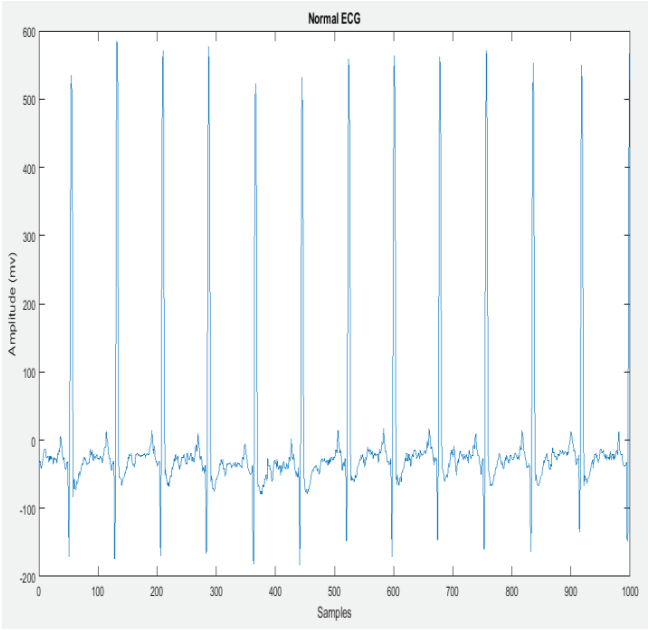

Figure 2: ECG signal of Normal Sinus Rhythm

3. The extracted ECG signal is decomposed into five levels of detail coefficients using 'db10' and saved in variables D1, D2, D3, D4, D5 in matrix form. The extracted coefficients of levels 1, 2, 3, 4, 5 are saved in D1, D2, D3, D4, D5 respectively. D1 coefficients of normal ECG in one channel, D2 coefficients of normal ECG in one channel is shown in Figure 3. D3 coefficients of normal ECG in one channel, D4 coefficients of normal ECG in one channel, D5 coefficients of normal ECG in one channel is shown in Figure 4.

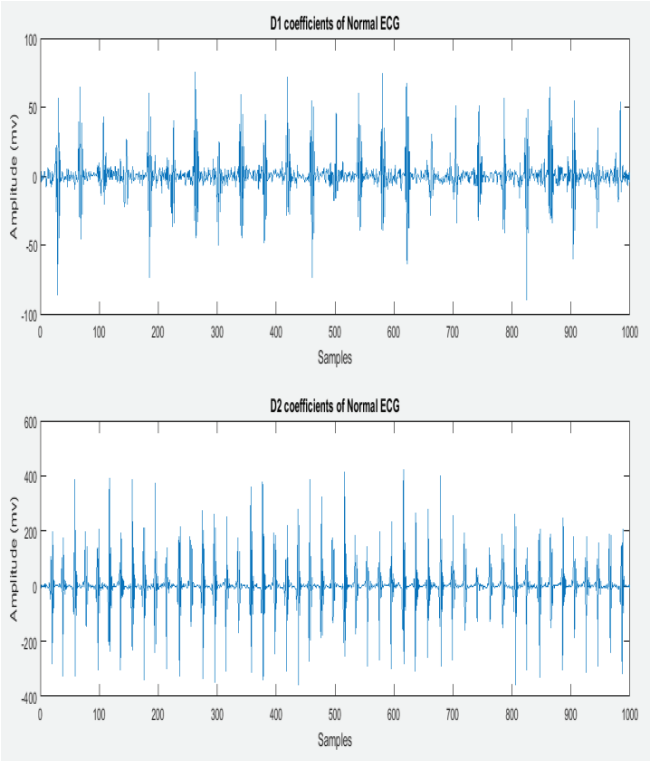

Figure 3: D1, D2 extracted from normal ECG

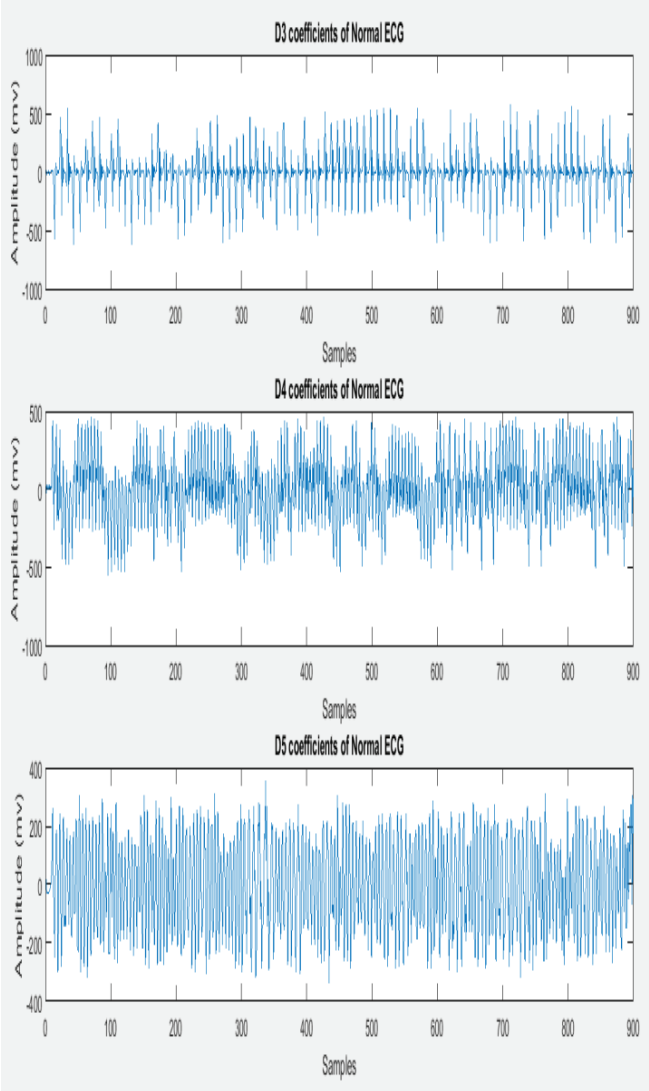

Figure 4: D3, D4, D5 extracted from normal

4. Then, extracted ECG signal is decomposed into five levels of approximation coefficients using 'db10' and saved in variables A1, A2, A3, A4, A5 in matrix form [11]. Coefficients of level 1 (A1), level 2 (A2), level 3 (A3) are shown in Figure 5 and coefficients of level 4 (A4), level 5 (A5) are shown in Figure 6.

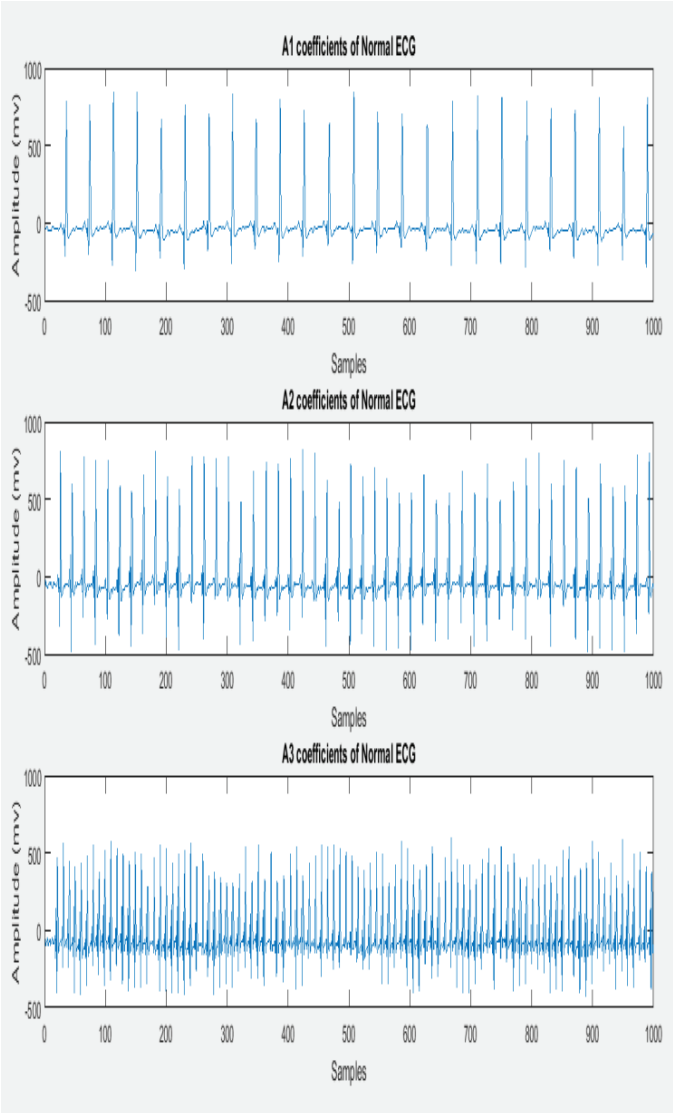

Figure 5: A1, A2, A3 extracted from normal ECG

5. Skewness, Kurtosis, Standard Deviation of each of D1, D2, D3, D4, D5 are calculated and stored in variables ske1, kur1, sd1; ske2, kur2, sd2; ske3, kur3, sd3; ske4, kur4, sd4; ske5, kur5, sd5. Therefore, a total of 15 features have been extracted.

6. Similar values for A1, A2, A3, A4, A5 are stored in variables aske1, akur1, asd1; aske2, akur2, asd2; aske3, akur3, asd3; aske4, akur4, asd4; aske5, akur5, asd5. Again a total of 15 features have been extracted. So, there are a total of 30 features.

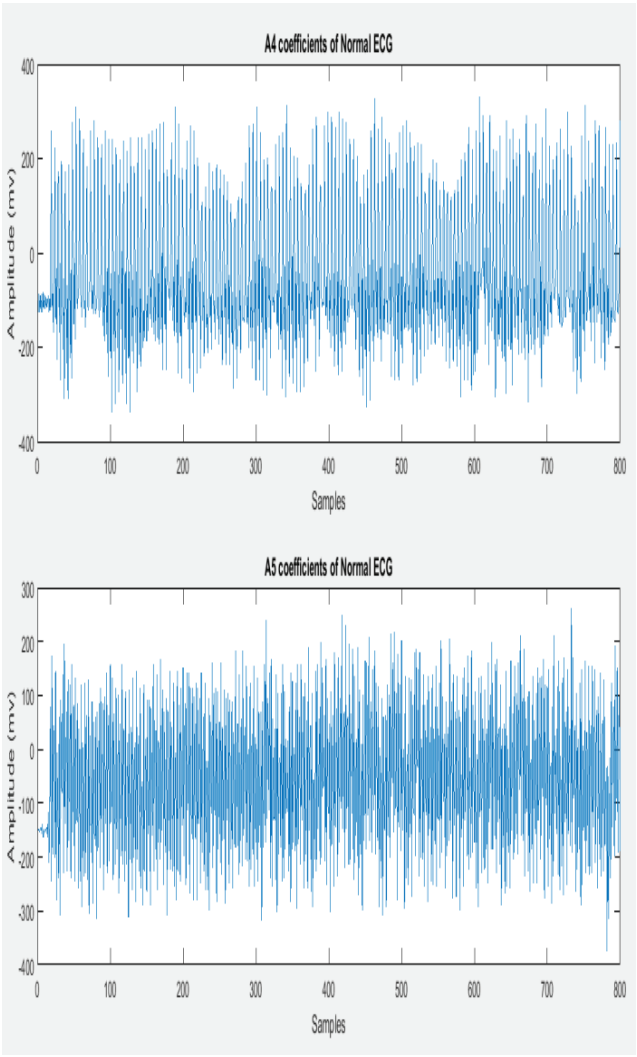

Figure 6: A4, A5 extracted from normal ECG

7. These statistical parameters of both detail and approximation coefficients are saved in the first row of a variable aa.

8. A value of '1' is assigned to the first row of another matrix (namely group matrix) for the first row of aa indicating that it was a normal ECG signal.

9. Identical operation is carried out for the other dimension of ECG signal for this record of normal ECG [12].

10. Hence, the same operation is carried out for a total of 14 times as there are 14 normal ECG signals.

11. Group matrix for normal ECG is created.

12. In the same manner group matrix for 105 abnormal ECG signals is also created with the difference being that a value of '0' is assigned for indicating abnormal ECG. This implies that same statistical features have been extracted for abnormal ECG too. So, the group matrix will have 119 rows and 1 column.

13. So, the final feature matrix will have 119 rows (since the total number of signals is 119) and 30 columns (total number of features are 30).

The discrete wavelet changes (DWT) is an execution of the wavelet transform utilizing a discrete arrangement of the wavelet scales and interpretations complying with some characterized standards. In other words, the signal is broken down into mutually orthogonal arrangement of wavelets using this transform, which is distinguishes itself the continuous wavelet transform (CWT). [15].

C. Abnormality Detection Method

1. The feature matrix and group matrix created in the feature extraction stage are used to train the Support Vector Machine.

2. Separate test matrices are created for normal and abnormal (diseased) ECG signals for testing the Support Vector Machine.

3. If the output of the SVM is '0' then it means that SVM has classified the test signal as an abnormal ECG signal. If the output is '1', then it means SVM has classified the test signal as a normal ECG signal.

4. Calculate the accuracy as it is already known which signal is normal and which one is not.

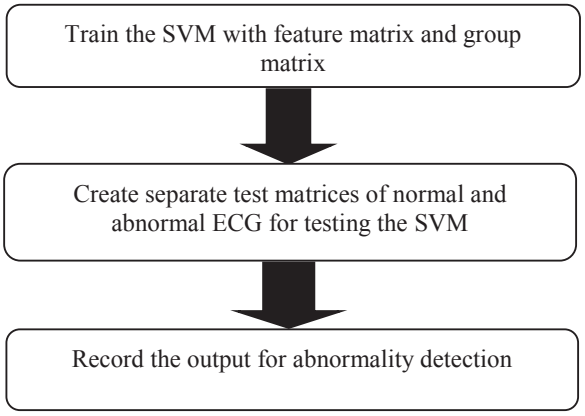

Figure 7: Workflow for abnormality detection

However, in our work we used Support vector machine (SVM) which is a supervised learning method that analyzes data and recognizes patterns, used for classification (machine learning) and regression analysis. The standard SVM is a binary linear classifier. A purpose of a binary classifier is to predict which of the two classes the input belongs. Hence, for a set of training examples, each labeled as belonging to one of two categories, an SVM training algorithm fabricates a model that predicts category or label of the of the input. Intuitively, the examples that are used to build the SVM model can be thought of as points in space, mapped in such a way that examples of the separate categories or labels are divided by a gap that can be as wide as possible. For every new example, it is then mapped into that same space and the category of the example is predicted by utilizing the information on which side of the gap they fall on.

D. Performance Metrics

The performance of the abnormality detection method is evaluated by the widely used metrics: accuracy (AC), sensitivity (SE), specificity (SP). These metrics are calculated using the following equations:

$$AC = \frac{Total\ correctly\ classified\ recordes}{Total\ number\ of\ records} \times 100\% \dots\dots\dots\dots (1)$$

$$SE = \frac{True\ Positive}{True\ Positive + False\ Negative} \times 100\% \dots\dots\dots\dots\dots (2)$$

$$SP = \frac{True\ Negative}{True\ Negatives + False\ Positive} \times 100\% \dots\dots\dots\dots\dots (3)$$

The explanation of the terms True Positive (TP), True Negative (TN), False Positive (FP), False Negative (FN) are given below:

FP: Normal class classified as abnormal
TP: Abnormal class classified as abnormal
FN: Abnormal class classified as normal
TN: Normal class classified as normal

The performance metrics are explained here which are going to be used to evaluate the performance of abnormality detection method. Then SVM has been described comprehensively as it was instrumental in the completion of this proposed work. A step by step workflow of the abnormality detection method has been given too.

III. RESULTS AND DISCUSSION

Here, the important data for classifying abnormal ECG signals are presented in tabular form. A final overall result is presented in this chapter. The result and the procedure has been compared with other pre-existing methods here later.

A. Data Used For Feature Extraction

First, 7 recordings i.e. a total of 7 ECG records representing Normal Sinus Rhythm were used for feature extraction in our work. These signals were collected from MIT-BIH Normal Sinus Rhythm Database. Then the features of ECGs exhibiting Myocardial Infarction were extracted. The ECG records exhibiting Myocardial Infarction were collected from PTB Diagnostic ECG Database. The records are given in Table I and Table II.

Table I and Table II contain the records used for feature extraction and training the Support Vector Machine in order to detect abnormal ECG signals. The records given in Table I are taken from 7 subjects who exhibited normal sinus rhythm. All the ECG records are of same duration which made the wavelet decomposition convenient as all detail coefficient and approximation coefficient matrices at the same level had equal size. Skewness, Kurtosis, Standard Deviation of the aforementioned records were then calculated.

TABLE I. ECG recordings of Normal Sinus Rhythm

Record	Age	Sex	Duration (Hour:Min:Sec)
16265m	32 years	Male	2:10:12
16272m	20 years	Female	2:10:12
16273m	28 years	Female	2:10:12
16420m	38 years	Female	2:10:12
16483m	42 years	Male	2:10:12
16539m	35 years	Female	2:10:12
16773m	26 years	Male	2:10:12

TABLE II. ECG recordings of Myocardial Infarction

Record	Age	Sex	Duration
s0010rem	81 years	Female	38 min
s0014lrem	81 years	Female	1h 55min
s0015lrem	58 years	Female	1h 55min
s0016lrem	81 years	Female	1h 55min
s0017lrem	63 years	Male	1h 55min
s0020arem	69 years	Male	1h 55min
s0020brem	69 years	Male	1h 55min

Table II contains the records of abnormal ECG signals used to complete the rest of the training of the Support Vector Machine which were collected from PTB Diagnostic ECG Database. Each record includes 15 simultaneously measured signals: the conventional 12 leads (i, ii, iii, avr, avl, avf, v1, v2, v3, v4, v5, v6) together with the 3 Frank lead ECGs (vx, vy, vz). Each signal is digitized at 1000 samples per second. All the patients in the records were diagnosed with Myocardial Infarction. Age of the patients range from 58-81 years. Though duration of every record is not same, the problem was eradicated using appropriate MATLAB functions. To match the lengths of each files, zeros were appended for files that have shorter duration.

B. Overall Result

The following table includes the final output of our proposed i.e. it represents the SVM's ability to detect abnormal ECG signal.

TABLE III. Performance of the proposed abnormality detection method

Number of ECGs	Diagnosis of ECG	Number of ECGs classified as abnormal ECG	Number of ECGs classified as normal ECG
36	Abnormal	36	0
36	Normal	1	35

TABLE IV. Performance of the proposed abnormality detection method (continued)

Number of ECGs	Accuracy	Sensitivity	Specificity
36	98.61%	97.37%	97.22%
36			

From Table III and Table IV, it can be seen that a total number of 72 ECG signals were tested to evaluate the performance of the proposed abnormality detection method. Equal number of normal ECGs (ECGs that exhibit normal sinus rhythm) and abnormal ECGs (ECGs that exhibit cardiac diseases), which means 36 normal and 36 abnormal ECGs were tested by the SVM. When tested, SVM showed the numerical value '0' for all the abnormal signals. Hence, all the abnormal ECGs were correctly classified. While testing the normal ECGs, the SVM showed the numerical value '1' for one abnormal ECG which means it classified one abnormal ECG as a normal ECG. Accuracy, sensitivity, specificity is calculated too.

C. Comparison with Some Pre-existing Methods

Given in this section is a comparison with some of the pre-existing methods for detection of abnormal ECG signal. All the works have used the PTB Diagnostic Database. Two separate tables are used to draw a complete comparison with the results of our proposed method with seven different methods. The metrics chosen for comparison are the feature set used for feature extraction, method of classification, accuracy, sensitivity, specificity. All the aforementioned metrics were obtained from the works mentioned in Table V and Table VI except for the work done by Hamed and Nasser, in which the specificity was not calculated.

TABLE V. Comparison with other works

Work By	Feature Set	Classification	Accuracy
Kumar et al. [16]	FAWT, SEnt	LS-SVM	99.31%
Hamed and Nasser. [17]	QRS complex	Shannon Energy	99.846%
Swati and Mitra [18]	XWT	Heart Rate	99.31%
Kora and Krishna [19]	WTC	LVNN, Bat	99.1%
Huang and Zhou [20]	Morphological, Slope, PCA	SDA, SVM, LLR	88.52%
Rai et al. [21]	Morphological	BPN, MLP, FFN	98.52%
Proposed Method	DWT, skewness, kurtosis, standard deviation	SVM	98.61%

TABLE VI. Comparison with other works (continued)

Work By	Feature Set	Sensitivity	Specificity
Kumar et al.	FAWT, SEnt	99.62%	98.12%
Hamed and Nasser.	QRS complex	99.924%	
Swati and Mitra	XWT	97.3%	98.8%
Kora and Krishna	WTC	96.97%	99.43%
Huang and Zhou	Morphological, Slope, PCA	89.68%	84.62%,
Rai et al.	Morphological	97.92%	96.5%
Proposed Method	DWT, skewness, kurtosis, standard deviation	97.37%	97.22%

From Table V and Table VI we can see that the performance metrics, namely: accuracy, sensitivity, and specificity of the proposed method is somewhat close to the other methods mentioned here. But, our proposed method differs from others in the choice of extracted feature set and the choice of classifier. Another advantage that our proposed method has over the others, is that it eliminates the need for any kind of pre-processing on the electrocardiogram signals before feature extraction. While other methods rely on the morphological features like R-R interval, Q wave, S wave, QRS complex etc and wavelet transforms, our proposed method utilizes the ability of daubechies wavelets (db10) to detect discontinuities and transients. Then skewness, kurtosis, standard deviation of the detail and approximation coefficients are used as features for training the SVM which improves performance since they can determine the extent of asymmetry of a distribution, measure the tailedness and determine dispersion. Hence, though the methods mentioned in Table V and Table VI yield almost similar results, our proposed method distinguishes itself by extracting the appropriate statistical features after the application of daubechies wavelet decomposition which eliminates the requirement of any pre-processing. This makes our proposed method simple yet accurate.

IV. CONCLUSIONS

ECG is instrumental when it comes to delivering important information about the cardiac conditions of a patient. Abnormalities in the ECG signal might be a symptom of a severe cardiac complication which can be life threatening. It is therefore necessary to detect an abnormal ECG signal and receive treatment from concerned personnel.

The method proposed here detects classifies an ECG signal into two groups: normal and abnormal. Eight cardiovascular conditions and diseases, namely: Angina, Bundle Branch Block, Cardiomyopathy Heart Failure, Dysrhythmia, Myocardial Hypertrophy, Myocardial Infarction, Myocarditis, Valvular Heart Disease, all are classified as ECG signals with abnormalities.

The whole procedure was carried out in MATLAB. Detail and approximation coefficients were used as the primary features and SVM was used to classify the ECG signals. The system proved to be quite efficient as it yielded an accuracy of 98.61%.

***Abstract*—Epilepsy is a neurological disorder originating from brain cells that can affect harshly on patients' life. Imbalance in electrical signals in the neuron cells results in involuntary partial or full body movements or other physiological symptoms. Seizure attack is unpredictable and during its occurrence patient may lose control which can cause serious injury even death. Medical facilities like medication or surgery can be done to improve living condition and life expectancy of patients. For these measures to be beneficial early and correct detection of epilepsy is crucial. However detection from scalp EEG is tough due to the presence of artifacts, the state of the brain and the frequency of seizure occurrence. Hence this study proposes a reliable model of detection system. A zero phase bandpass butterworth filter is used to extract only the EEG signal eliminating all physiological and device artifacts. Frequency distribution of brain signal in both interictal and ictal state differs from that in normal person. So statistical measurements that correctly maps these changes are used to classify the dataset. For classification, a nonlinear support vector machine is used on two sets of dataset combination. Performance of detecting epileptic signal even in the interictal state is promising for use in medical applications.**

***Index Terms*—Electroencephalogram, Bandpass filtering, Entropy, Power spectral density, Support Vector Machine.**

I. Introduction

Epilepsy is a neural disorder of the brain and can occur at any stage of life. It originates from excessive electrical discharges in some group of brain cells and is one of the world's oldest recognized abnormal conditions. For centuries people have feared this disease for its bizarre symptoms and unpredictability. For this reason people with such disorder were misunderstood and discriminated. This can impact very harshly on the quality of life for people with the disorder and their families. The main and only symptom of Epilepsy is Seizures and is defined as having two or more unprovoked seizures varying from the briefest lapses of attention or muscle jerks to severe and prolonged convulsions. Epileptic seizures have four different states: the preictal state, which is a state that appears before the seizure begins, the ictal state that begins with the onset of the seizure and ends with an attack, the postictal state that starts after ictal state, and interictal state that starts after the postictal state of 1st seizure and ends before the start of preictal state of consecutive seizure [1]. However, there are different kinds of seizures which can affect people in different ways depending on where in the brain region it originates. Seizures can occur from a few seconds to a few minutes leading to greater damage if it stays longer. The most common form of seizures are unconsciousness, muscle stiffness or convulsion. But there are some other form that are harder to notice like the patient may stare into space for a few seconds. Others may cause only a few muscle twitches, a turn of the head, or a strange smell or visual disturbance that only he/she can sense. During a seizure attack the electrical activity in the brain show abnormal behavior and when it ends brain activity starts to go back to normal. A person is diagnosed as epileptic if two unprovoked seizures attack occurs (or one unprovoked seizure with the likelihood of more) that were not caused by some known and reversible physical condition like alcohol withdrawal or extremely low blood sugar. Epilepsy may start due to various reason. Some epilepsy is genetic and the way one or more genes work in the brain may provoke seizure. Structural change in the neuron cells can also introduce seizure attack. Infection, tumors and injury in the brain may causes seizure at a later time in life. Now a days strokes is one of the most common causes of new onset seizures.

Approximately 50 million people currently live with epilepsy worldwide with an estimated 2.4 million people diagnosed with epilepsy each year. Close to 80% of people with epilepsy live in low and middle income countries among whom 70% can be cured with medication [2]. The most severe threat of this disorder is its unpredictability preventing the patient from normal activities like swimming, driving, crossing a street etc. Epileptic patients can be treated with drugs or surgical procedures [3]. This severity can be subsided with proper detection and classification of epileptic patients ensuring correct treatments to avoid dire consequences, especially for those whose condition is difficult to diagnose clinically, such as those with multiple forms of epilepsy including masked and unusual forms of epilepsy [4]. If the detection can be made properly, then measures to prevent/cure seizure can be taken resulting in prevention of severe injury and even death. However a visual inspection of brain signal recording is time consuming and can be erroneous due to fatigue and other factors. Therefore a correct automatic detection is highly convenient.

There is a massive difference between the frequency dis-

tribution of epileptic and non-epileptic Electroencephalogram (EEG) signal and it can be effectively used in the detection process. In this paper, the focus is to detect epileptic patient with single channel EEG irrespective of the presence of seizure attack and create a generalized detection system. The work is done in three steps such as preprocessing, feature extraction and classification. The binary classifier considers the two normal datasets (Eye open and eye closed) as nonepileptic signal and the other three sets interictal (Signal from epileptic zone and opposite hemisphere) and ictal as epileptic signal.

II. Literature Review

In detecting epileptic seizure preictal and ictal states can be efficiently used since they indicates whether a seizure is going to occur and the actual occurrence. For decades researchers are trying to detect epilepsy with maximum sensitivity. In [1], Usman et. al. have proposed an algorithm for seizure prediction using both statistical moments and spectral features where the signal was first decomposed into frequency bands by empirical mode decomposition. They observed average prediction time of epileptic seizure as 23.48 minutes before the onset of the seizure with average sensitivity as 92.23% and specificity as 93.38%.

Entropy has been used as a measure of the complexity or uncertainty, of an EEG (Electroencephalography) signal, where the more chaotic the signal is, the higher the entropy is [5]. Many authors agree that, during a seizure, the brain activity is more synchronous than during a normal, nonseizure phase [5] [6]. Fergus et al. [6] took four entropy measurements and other features. The EEG channels were grouped into regions and top five features per region were selected based on their rank determined by the linear discriminant backward search technique. They used KNNC classifier that achieved 93% sensitivity and 94% specificity.

A different more data adaptive approach has been adopted in [4]. Accuracy of identification system may decline drastically, if signals are recorded under different conditions and have different data distribution [4]. They used transductive transfer learning mechanism for regression and binary classification including fuzzy rules for better learning and stronger modeling of uncertainty. A. T. Tzallas [7] et. al. approached a time-frequency (t-f) analysis where features including energy distribution in the t-f plane were used. They used artificial neural network for classification and achieved 89% accuracy. In [8] features including nonlinear, time, frequency and time-frequency domain extracted from fewer subbands were analyzed. A quadratic classifier achieved an overall accuracy of 98.7%.

In this study, signal in the frequency spectrum 0.5 Hz - 30 Hz is considered only since below 0.5 Hz range contains mainly device artifacts and the major important rhythmic components of the EEG signal lies in this range. Variance and frequency distribution in the brain during seizure attack and in normal state differs vastly. Hence features such as entropy, power spectral density and root mean square are used. Segmentation of the dataset into fewer seconds enhances classification accuracy greatly as seizure may occur only for a couple of seconds. Thus a 3 second trial of the original better captures the pattern and frequency distribution.

III. Data and Proposed Method

A. Data Description

The publicly-available Bonn database [9] was used in this study. The whole dataset consisted of five sets (denoted as Z, O, N, F, and S) and each of them contains 100 single-channel EEG segments of 23.6 seconds duration with sampling frequency of 173.61 Hz. Sets Z and O were taken from five healthy subjects. The subjects were awake and relaxed with their eyes open (set Z) and closed (set O), respectively. The last three sets were obtained from five epileptic patients. Sets N and F contained activity measured during seizure-free intervals, among which set F was recorded from within the epileptogenic zone and set N from the hippocampal formation of the opposite hemisphere. Set S contained only seizure activity [10]. They were further grouped into three classes – normal (sets Z and O), interictal (sets N and F), and ictal (set S) classes. The EEG for five datasets with single channel is illustrated in "Fig. 1".

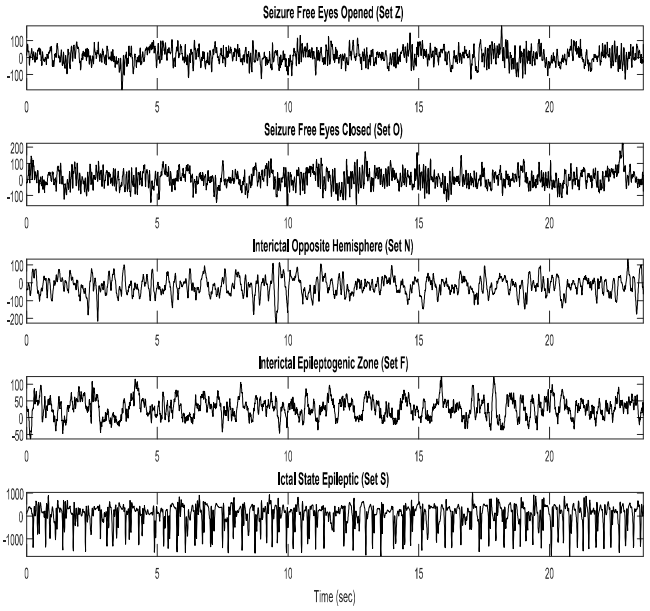

Fig. 1. Single channel EEG signal of length 23.6 sec for five datasets

B. Proposed Algorithm

This paper approaches a generalized detection system that aims to detect epileptic patient even in the interictal state. EEG signal represents neural activity thus it perfectly reflects a persons brain state. There is a distinct difference in the frequency distribution of normal and epileptic EEG. However frequency information decays vary rapidly over time, hence the window in consideration plays an important role in the detection process. Epileptic seizures may last from couple of seconds to minutes [11] and hence in this work a 3

seconds window is used to properly locate seizure features. The proposed method is depicted in "Fig. 2".

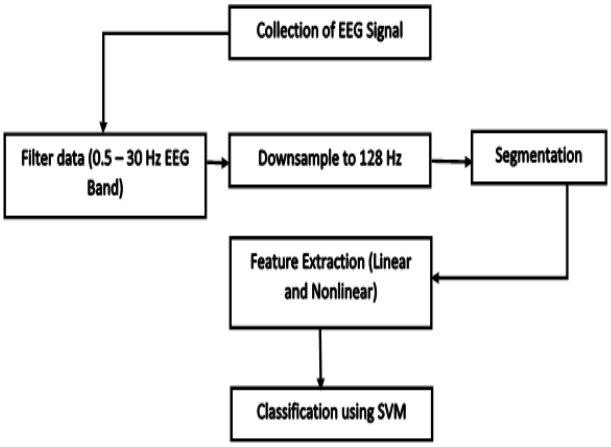

Fig. 2. Flowchart of epilepsy detection system

Steps in proposed method:

i The EEG signal is first downsampled and filtered using a zero phase band pass filter to contain only the desired rhythmic components.
ii The filtered signal is then segmented in 3 seconds trial to better capture the features.
iii Then features including approximate entropy, power of peak frequency and root mean square are calculated for each trial.
iv Finally the features are used to detect and classify the epileptic and nonepileptic signal using support vector machine.

IV. Implementation

A. Preprocessing

Each of the five sets of data are first downsampled to 128 Hz to reduce number of samples per second and to eliminate fractional numbers. It later helps perfect segmentation also. Then a zero phase butterworth band pass filter with cut off frequency at 0.5 - 30 Hz is applied. Being zero phase the filter does not affect the phase of the signal and the cut off range ensures that only the rhythmic components of the EEG signal is remained and all other physiological and electrical artifacts and noises are removed. The frequency response of the butterworth filter is best that other filters and produces cleaner cutoff in the passband and stopband. Thus this maximally flat filter works best for filtering noisy data like EEG. As epileptic seizure remains only for a couple of seconds to minutes, the data are segmented into 3t seconds trials to perfectly capture the frequency information resulting in more accurate classification. Thus the whole dataset was segmented into 7 trials for each set.

B. Feature Extraction

Entropy calculation is very popular now a days in epilepsy detection. When a seizure occurs, the brain signal becomes more synchronous than its normal state [12]. The variance right before and during a seizure attack is very high as compared to a normal brain signal. The higher the variance in a signal, the more information it carries. Thus complexity is an important feature and can be calculated using approximate entropy. In other words, approximate entropy calculates the uncertainty of a brain signal. It is unaffected by noise and robust to artifacts and outliers, hence perfect for EEG signal analysis [13]. It is described as

$$\phi^m(r) = \frac{1}{N-m+1}\sum_{i=1}^{N-m+1} \log C_i^m(r), \quad and$$
$$ApEn(m,r,N)(u) = \phi^m(r) - \phi^m + 1(r); \quad m \geq 1 \qquad (1)$$

where $\phi^m(r)$ is relative prevalence of repetitive patterns of length m. The approximate entropy values for five datasets is illustrated in "Fig. 3".

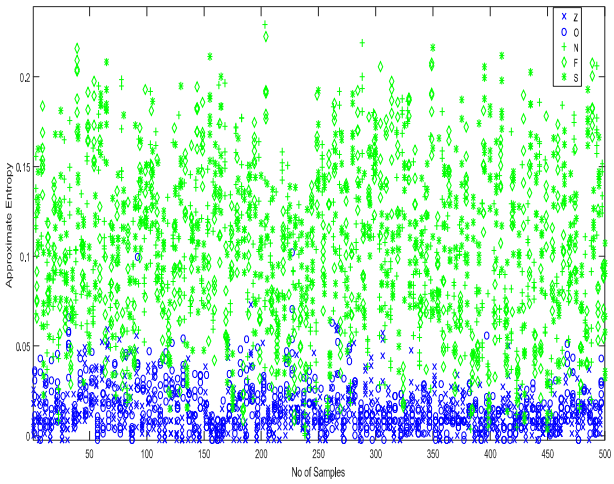

Fig. 3. Approximate entropy values of all five dataset

The power spectral density (PSD) of a signal describes the power present in the signal as a function of frequency, per unit frequency. Frequency resolution and its distribution in the signal reveals in PSD which are invisible otherwise. When a seizure occurs, a major cyclic component emerge in the EEG signal which shows itself as a dominant peak in frequency domain [14]. Thus in power spectral density representation, there is a distinct difference between the power of the peak frequency of epileptic and nonepileptic signal. Peak frequency is described as

$$f_{max} = arg\left(\frac{f_s}{N}\max_{i=0}^{N-1} P(i)\right) \qquad (2)$$

where f_s and N describe the sampling frequency and total number of samples, respectively. Dominant peak frequencies

can effectively help in the classification. In this study the power of the maximum peak in PSD is taken for each trial. The power of peak frequency in power spectral density (PSD) for five datasets is illustrated in "Fig. 4".

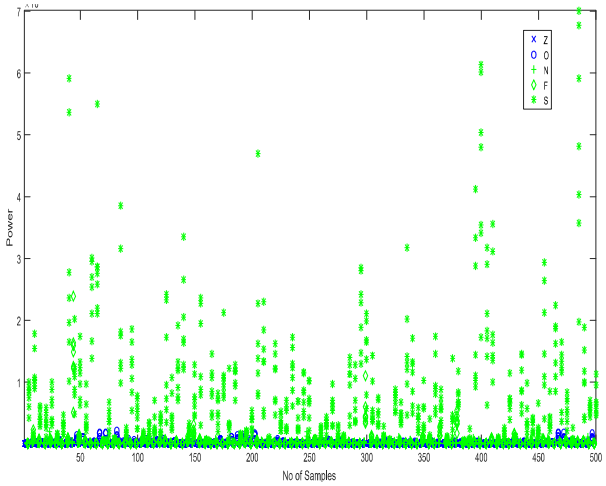

Fig. 4. Power of peak frequency in PSD for all five dataset

Root mean square measures the strength of a signal is also used in this work as a feature. During seizure brain activity is disturbed with sudden electrical discharges. This phenomena can effectively be captured with RMS value. To calculate RMS, square root of the mean square of the signal values is taken. It is described as

$$RMS = \sqrt{\frac{1}{N}\sum_{i=0}^{N-1} x(i)^2}, \tag{3}$$

where N describes the total number of samples. The root mean square values (RMS) for five datasets is illustrated in "Fig. 5".

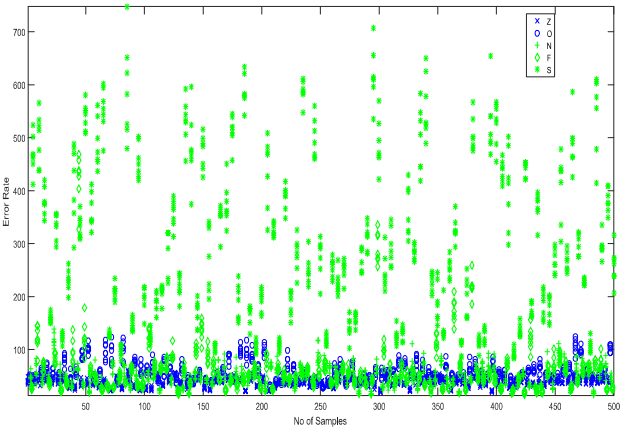

Fig. 5. Root Mean Square values for all five dataset

V. Experimental Results and Discussion

A. Classification

Support vector machine maps the training dataset in a two dimensional plane and separates these data into two parts using a hyperplane. Finally new data is categorized using this hyperplane. The hyperplane is placed in such way that maximizes distance from the data points. Hyperplane can be linear or nonlinear but since features in this work are overlapped and cannot be separated with a linear line, a nonlinear kernel is used. Kernel function transforms the dataset in a multidimensional space. Let us assume a training dataset of n points of the form

$$(\vec{x}_1, y_1), ..., (\vec{x}_n, y_n), \tag{4}$$

where y_i is either 0 or 1 indicating the label of x_i is given. There are many types of kernel functions to map the feature space in higher dimension. A second order or quadratic polynomial is best for this work since higher orders tend to overfit the training data. The polynomial kernel is defined as

$$K(\vec{X}, \vec{Z}) = (\vec{Z}^T \vec{X} + C)^n, \tag{5}$$

where n is the order of the kernel and C is a constant to trade-off the influence of higher order and lower order components. A soft margin is used to computer the classifier. The goal is to minimize this margin of the following form

$$f(\vec{w}, b) = \left[\frac{1}{n}\sum_{i=1}^{n} \max(0, 1 - y_i(w.x_i - b))\right] + \lambda||w||^2, \tag{6}$$

f is a convex function of w and b where w is the weight factor, b is bias and λ determines the trade-off between increasing the margin size and keeping x_i in the correct side of the margin.

The total dataset is divided into 2 sets: 60% for training and 40% for testing. The work is done in two sets of combination: first set Z, O and S is used where Z and O are normal and S is epileptic signal in ictal state and in the second phase all five sets are used where Z and O are labeled as normal and N, F and S are labeled as epileptic signal. A nonlinear quadratic support vector machine is used to classify the data. For combination of all five sets of data accuracy is 92.5%, sensitivity 87.5% and Specificity 100%. However the first combination of Z, O and S give an accuracy of 100%. The classification result is given in "Table. I".

TABLE I
Confusion Matrix of Proposed Method

n = 200	**Predicted: No**	**Predicted: Yes**	**Total**
Actual: No	TN = 79	FP = 1	80
Actual: Yes	FN = 11	TP = 109	120
	90	110	

The binary classifier performance at various threshold settings is determined by plotting true positive rate against false

positive rate and higher slope represents better performance in distinguishing epileptic and nonepileptic person. The receiver operating characteristic (ROC) curve is given in "Fig. 6". For classification using support vector machine, linear and nonlinear approach with different kernel functions such as RBF, polynomial, gaussian etc were tested and the quadratic classifier provided the best results. A performance comparison with other research work on the same dataset is given in "Table. II". Though accuracy degrades when interictal signal from both epileptic zone and from opposite hemisphere of the brain is added but it is noticeable that the accuracy is better with the five dataset combination than other related works. The overall accuracy is 94% with sensitivity 90.8% and specificity 98.75%.

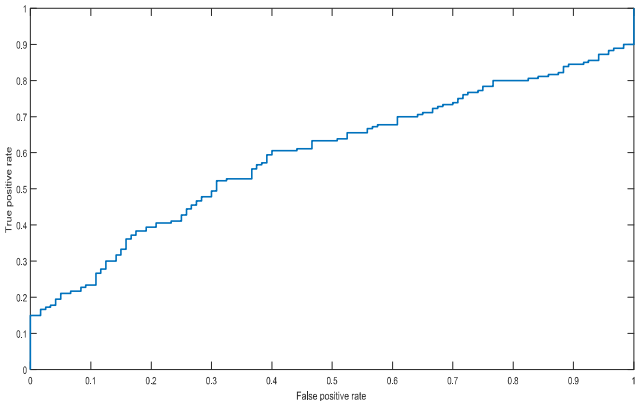

Fig. 6. Receiver Operating Characteristic (ROC) curve of Proposed Method

TABLE II
METHODS AND PERFORMANCE COMPARISON

Authors	Methods	Dataset	Accuracy
C. Yang [4] et. al.	Transductive transfer learning methods	Z,S	≥96%
		Z,F,S	≥96%

Proposed Method	Approximate Entropy, RMS PSD, Quadratic SVM	Z,O,S	100%
		Z,O,N,F,S	94%

VI. CONCLUSIONS

Epilepsy is a neurological disorder and in chronic state it can threaten one's life. Proper early detection can facilitate treatment. However seizures are unpredictable and presents only for a very short duration. Hence it is not practical to detect epilepsy from ictal state only. This study aims to detect epilepsy in both ictal and interictal state to enhance the efficiency of the detection system in all brain state. Observation of the feature vectors represents that the brain signal pattern in normal and epileptic patients has very different statistical distribution. Nonlinear quadratic support vector machine can effectively use these phenomena to classify the signal. While this study only aims to perform a binary classification of epileptic and nonepileptic signal, it can be applicable to predict seizure attack in advance as well. For example, entropy calculation can used to detect the pattern of a preictal brain state. In focal epilepsy, identifying the brain region of origin of epileptic seizure precisely can facilitate surgery to remove the affected brain cells. However this requires further study and analysis. In future discourse this issue will be addressed.

***Abstract*—In this paper, a novel method for estimation of the parameters of autoregressive (AR) systems in the presence of additive noise is presented. This method models the autocorrelation function (ACF) of the noisy AR signal as a sum of non-increasing complex exponentials and then estimates its parameters using the matrix pencil method. We improve upon this basic method by fitting the noisy AR signal to a higher order AR model and using its parameters to calculate a parametric ACF of the noisy signal which makes the pole extraction process using the matrix pencil method stable and more accurate. We show that this method can accurately estimate the parameters of an AR system in noise in a single pass even at a very low (-5dB) signal-to-noise ratio (SNR).**

***Index Terms*—autoregressive system, parameter estimation, matrix pencil method, low signal-to-noise ratio**

I. Introduction

Signal modeling using autoregressive systems is ubiquitous in many different fields of science and engineering such as speech analysis, economics, radar and sonar systems, seismology and biomedical signal processing. While the estimation of parameters of an AR system in absence of additive noise is straightforward with well-known methods like the Yule-Walker method or the Burg algorithm [1], in practice, the desired signal is often corrupted by observational noise. The presence of noise causes biased estimation of model parameters when the methods devised for the noise-free case are used without any modification [2]. Also, this estimation problem becomes exceedingly hard at very low signal-to-noise ratios (SNR) [3]. So, more sophisticated methods are required to estimate the AR model parameters in the presence of a high level of noise. Several methods have been proposed for parameter estimation of noisy AR systems. As an AR system in the presence of additive noise can be modeled as an ARMA system [4], a commonly used method is to use an ARMA parameter extraction method, like prediction errors methods [5] to estimate the parameters of the AR system. Another common approach to account for observational noise is to adopt a noise compensation technique such as the noise compensated lattice filter approach [6]. However, noise compensation based methods usually require an *a priori* knowledge of the noise variance. The conventional Yule-Walker method can be modified to devise the high-order Yule-Walker method for noisy AR systems which utilizes the autocorrelation coefficients at higher lags. However, this approach is prone to singularity problem of the autocorrelation matrix [7]. Among other methods, the improved least squares method with no prefiltering (ILSNP) of noisy observations reported in [8] provides accurate estimates of the AR parameters at a high SNR.

All of the methods mentioned above work well down to some positive value of the SNR. At very low SNRs, such as close to 0dB or negative SNRs, damped sinusoidal modeling of the autocorrelation function (ACF) is shown to produce a reliable estimation of the AR parameters [3], [9]. In [3] a direct approach based on the scanning of the z-plane is proposed which is very computationally expensive. In a later work, a modified empirical mode decomposition (EMD) based approach [9] is proposed to reduce the computational cost. In both cases, the poles are estimated sequentially one by one which requires that we assume the damped sinusoidal components are either orthonormal (for the scanning approach) or corresponds to separate intrinsic mode functions (for the EMD approach). Both of these approaches are heuristic in the sense that they are based on empirical observations. Although the EMD based approach does not require scanning the z-plane exhaustively, it is still computationally expensive due to the iterative nature of EMD. Both these approaches have been devised for real-valued signals only and their extension for complex-valued signals have not been explored. In this paper, the basic concept of modeling the ACF as a non-increasing sum of complex exponentials (or complex sinusoids) is adopted, while the shortcomings of the previous methods have been addressed. Several very efficient and reliable methods of estimating parameters of exponential sums have been proposed in the literature [10]. In this paper, the reliable matrix pencil [10], [11] method of estimating parameters of exponential sums is used to estimate the poles from the ACF simultaneously, with high precision and at a relatively much lower computational cost. However, this method requires relatively good estimates of the autocorrelation coefficients at higher lags, and can sometimes suffer from numerical instability or prediction errors if a naive approach is used

for estimating the ACF. So, we propose a more accurate method of estimating the ACF by first over-parameterizing the AR signal, i.e. modeling it as a high order AR signal and using the estimated parameters of the high order AR model to compute a parametric ACF which provides a much more accurate low-variance estimate of the ACF at higher lags and thus also solves the instability problem. The proposed method is principled, computationally efficient as it only uses a single pass to estimate the parameters and also directly applicable to complex signals. It successfully solves the shortcomings of [3] and [9] while also producing more accurate estimates at very low SNR levels (as low as -5dB).

II. Problem Formulation

The observed signal $x(n)$ is modeled as a superposition of a pth order autoregressive signal $y(n)$ and the observational noise $v(n)$.

$$x(n) = y(n) + v(n) \tag{1}$$

For the simplest case, we will assume that $v(n)$ is a Gaussian white noise with its samples being drawn independently from the normal distribution $\mathcal{N}(0, \sigma_v^2)$. The AR signal $y(n)$ can by modeled by the difference equation

$$y(n) = -\sum_{k=1}^{p} a_k y(n-k) + u(n) \tag{2}$$

Where, $a_k, k = 1, 2, ..., p$ are the AR parameters and $u(n)$ is a Gaussian white noise with its samples being drawn from the distribution $\mathcal{N}(0, \sigma_u^2)$. It is assumed that the input noise $u(n)$ and the observational noise $v(n)$ are independent of each other.

Another way of modeling this AR signal is as the output of a causal, infinite impulse response (IIR) system with p poles and the noise $u(n)$ as its input.

$$y(n) = h(n) * u(n) \tag{3}$$

Where the impulse response of the system $h(n)$ has the difference equation representation

$$h(n) = \begin{cases} -\sum_{k=1}^{p} a_k h(n-k) + \delta(n) & \text{for } n \geq 0 \\ 0 & \text{for } n < 0 \end{cases} \tag{4}$$

In the z-domain $h(n)$ has the representation

$$H(z) = \frac{1}{1 + \sum_{k=1}^{p} a_k z^{-k}} \tag{5}$$

Or in terms of poles as

$$H(z) = \frac{1}{\prod_{k=1}^{p} (1 - z_k z^{-1})} \tag{6}$$

Here, $z_k, k = 1, 2, ..., p$ are the poles of the AR system and are the solutions to the polynomial equation $1 + \sum_{k=1}^{p} a_k z^{-k} = 0$. The region of convergence (ROC) of $H(z)$ is $|z| > |z_m|$ where z_m is the outermost pole i.e. $|z_m| \geq |z_i|, i = 1, 2, ..., p$. Since, the system is assumed to be stable, the ROC must include the unit circle in the z-plane and all its poles must lie within the unit circle.

The problem of identification of a noisy AR system involves estimation of the AR parameters $(a_k, k = 1, 2, ..., p)$ or the poles $(z_k, k = 1, 2, ..., p)$ from the noisy signal $x(n)$. Additionally, we may be interested in estimating the variances of the input noise (σ_u^2) and the observational noise (σ_v^2).

III. Proposed Method

The autocorrelation function (ACF) of the noise-free AR signal is

$$r_y(m) = \mathbb{E}[y(n)y^*(n-m)] = \sigma_u^2 r_h(m) \tag{7}$$

Where, the autocorrelation of the impulse response $h(n)$ is

$$r_h(m) = h(m) * h^*(-m) = \sum_{n=-\infty}^{\infty} h^*(n)h(n+m) \tag{8}$$

A detailed derivation of this expression can be found in [12]. Since, the input noise $u(n)$ and the observational noise $v(n)$ are assumed to be independent, the ACF of the noisy AR signal is simply

$$r_x(m) = \mathbb{E}[x(n)x^*(n-m)] = r_y(m) + \sigma_v^2 \delta(m) \tag{9}$$

$$= \sigma_u^2 r_h(m) + \sigma_v^2 \delta(m) \tag{10}$$

So, the ACF of $x(n)$, for lags other than zero ($m \neq 0$) is (ideally) a scaled version of the autocorrelation of the impulse response. However, since we have to use finite length samples of $x(n)$ in practice, the estimated ACF will be noisy.

Our goal is to model $r_x(m)$ for $m > 0$ as a sum of non-increasing exponentials and then use the Matrix Pencil method to estimate its poles. We will make use of the following lemmas in devising our method.

Lemma 1. *Any causal and bounded sequence that has a proper function representation in the z-domain and does not have any repeated poles, can be expressed as a sum of non-increasing exponentials.*

Proof. Let $h(n)$ be a causal sequence such that

$$h(n) = \begin{cases} -\sum_{k=1}^{p} a_k h(n-k) + \sum_{l=0}^{q} b_l \delta(n-l) & \text{for } n \geq 0 \\ 0 & \text{for } n < 0 \end{cases} \tag{11}$$

Where $q < p$. Then, it has a proper function representation in the z-domain

$$H(z) = \frac{\sum_{l=0}^{q} b_l z^{-l}}{1 + \sum_{k=1}^{p} a_k z^{-k}} \tag{12}$$

$H(z)$ can be written in terms of poles $z_k, k = 1, 2, ..., p$ as

$$H(z) = \frac{\sum_{l=0}^{q} b_l z^{-l}}{\prod_{k=1}^{p} (1 - z_k z^{-1})} \tag{13}$$

Assuming no repetition of poles, by partial fraction decomposition we can write

$$H(z) = \sum_{k=1}^{p} \frac{C_k}{1 - z_k z^{-1}} \tag{14}$$

Where,

$$C_k = \frac{\sum_{l=0}^{q} b_l z_k^{-l}}{\prod_{\substack{k'=1 \\ k' \neq k}}^{p} (1 - z_{k'} z_k^{-1})} \tag{15}$$

By taking inverse z-transform we get

$$h(n) = \begin{cases} \sum_{k=1}^{p} C_k z_k^n & \text{for } n \geq 0 \\ 0 & \text{for } n < 0 \end{cases} \tag{16}$$

Lemma 2. *If a causal sequence can be expressed as a sum of non-increasing exponentials, the causal part (i.e. for non-negative lags) of its autocorrelation function can also be expressed as a sum of non-increasing exponentials with the same set of poles as the original sequence.*

Proof. The causal sequence under consideration

$$h(n) = \begin{cases} \sum_{k=1}^{p} C_k z_k^n & \text{for } n \geq 0 \\ 0 & \text{for } n < 0 \end{cases} \tag{17}$$

The causal part (lag $m \geq 0$) of the ACF of $h(n)$

$$\begin{aligned} r_h(m) &= \sum_{n=0}^{\infty} h^*(n) h(n+m) \\ &= \sum_{n=0}^{\infty} \sum_{l=1}^{p} C_l^* (z_l^*)^n \sum_{k=1}^{p} C_k z_k^{n+m} \\ &= \sum_{k=1}^{p} z_k^m \sum_{l=1}^{p} C_l^* C_k \sum_{n=0}^{\infty} (z_l^* z_k)^n \\ &= \sum_{k=1}^{p} z_k^m \sum_{l=1}^{p} \frac{C_l^* C_k}{1 - z_l^* z_k} \\ &= \sum_{k=1}^{p} \beta_k z_k^m \end{aligned} \tag{18}$$

Where,

$$\beta_k = \sum_{l=1}^{p} \frac{C_l^* C_k}{1 - z_l^* z_k} \tag{19}$$

Lemma 3. *If the causal sequence $h(n)$ can be expressed as a sum of non-increasing exponentials, its advanced and truncated form $h(n+l)\mathcal{H}(n);\ l > 0$ can also be expressed as a sum of non-increasing exponentials with the same set of poles, where $\mathcal{H}(n)$ is the heaviside step function.*

Proof. Let,

$$h(n) = \begin{cases} \sum_{k=1}^{p} C_k z_k^n & \text{for } n \geq 0 \\ 0 & \text{for } n < 0 \end{cases} \tag{20}$$

$$\text{Then, } h(n+l)\mathcal{H}(n) = \begin{cases} \sum_{k=1}^{p} C_k z_k^{n+l} & \text{for } n \geq 0 \\ 0 & \text{for } n < 0 \end{cases}$$

$$= \begin{cases} \sum_{k=1}^{p} D_k z_k^n & \text{for } n \geq 0 \\ 0 & \text{for } n < 0 \end{cases} \tag{21}$$

Where,

$$D_k = C_k z_k^l \quad \text{for } k = 1, 2, ..., p \tag{22}$$

A. Exponential Sum Model of the Autocorrelation Function

From (5) we see that $h(n)$ has a proper function representation in the z-domain. If we assume that the AR signal does not have any repeated poles, according to lemma 1, it can be expressed as a sum of non-increasing exponentials.

$$h(n) = \begin{cases} \sum_{k=1}^{p} C_k z_k^n & \text{for } n \geq 0 \\ 0 & \text{for } n < 0 \end{cases} \tag{23}$$

Now, according to lemma 2, $r_h(m)\mathcal{H}(m)$ can also be expressed as a sum of non-increasing exponentials, and according to lemma 3, so can be $r_h(m+1)\mathcal{H}(m)$

$$r_h(m)\mathcal{H}(m) = \sum_{k=1}^{p} \beta_k z_k^m \qquad \text{for } m \geq 0 \tag{24}$$

$$r_h(m+1)\mathcal{H}(m) = \sum_{k=1}^{p} \gamma_k z_k^m \qquad \text{for } m \geq 0 \tag{25}$$

Where,

$$\gamma_k = \beta_k z_k \tag{26}$$

From (10) we see that the ACF of the noisy AR signal $x(n)$ for lags greater than zero can be expressed as an exponential sum as well.

$$\begin{aligned} r_x(m+1)\mathcal{H}(m) &= \sigma_u^2 r_h(m+1)\mathcal{H}(m) \\ &= \sigma_u^2 \sum_{k=1}^{p} \gamma_k z_k^m \qquad \text{for } m \geq 0 \\ &= \sum_{k=1}^{p} c_k z_k^m \qquad \text{for } m \geq 0 \end{aligned} \tag{27}$$

Where,

$$c_k = \sigma_u^2 \gamma_k \tag{28}$$

We can estimate the poles z_k and the coefficients c_k (for $k = 1, 2, ..., p$) from this sum of exponential representation of $r_x(m+1)\mathcal{H}(m)$ by a method such as the matrix pencil method.

From (7), (24) and (26), the causal part of ACF of the noise-free AR signal $y(n)$ is,

$$\begin{aligned} r_y(m)\mathcal{H}(m) &= \sum_{k=1}^{p} \sigma_u^2 \beta_k z_k^m \qquad \text{for } m \geq 0 \\ &= \sum_{k=1}^{p} \sigma_u^2 \gamma_k z_k^{m-1} \qquad \text{for } m \geq 0 \\ &= \sum_{k=1}^{p} c_k z_k^{m-1} \qquad \text{for } m \geq 0 \end{aligned} \tag{29}$$

So, after estimating c_k and z_k we can estimate $r_y(m)$, and the variance of input noise from the first Yule-Walker equation as

$$\sigma_u^2 = r_y(0) + \sum_{k=1}^{p} a_k r_y^*(k) \tag{30}$$

The variance of observational noise can also be estimated from (9) as

$$\sigma_v^2 = r_x(0) - r_y(0) \tag{31}$$

B. Matrix Pencil Method

The matrix pencil method is a principled method for estimating the parameters of an exponential sum sequence, even in the presence of additive noise. For our purpose, we wish to determine the parameters (z_k, c_k) of the exponential sum representation of $r_x(m+1)\mathcal{H}(m)$, as presented in (27). Due to the finite length of the observed noisy signal $x(n)$, the estimated $r_x(m+1)\mathcal{H}(m)$ is noisy. The matrix pencil method is well-equipped to take additive noise into consideration. It directly estimates all poles simultaneously, in a single pass.

Two matrix pencil methods have been proposed in [10] - one based on QR decomposition and the other based on Singular Value Decomposition (SVD) of the Hankel matrix. We found that both of them performed satisfactorily for our task. But, we will discuss the rotationally invariant (ESPRIT) method based on SVD of the Hankel matrix and present our experimental results for the same. For notational convenience, let

$$s(m) = r_x(m+1)\mathcal{H}(m) \tag{32}$$

First, the rectangular $(M-L)\times(L+1)$ Hankel matrix $\boldsymbol{H}$ is formed using M samples of $s(m)$

$$\boldsymbol{H} = \begin{bmatrix} s(0) & s(1) & \dots & s(L) \\ s(1) & s(2) & \dots & s(L+1) \\ \vdots & \vdots & \ddots & \vdots \\ s(M-L-1) & s(M-L) & \dots & s(M-1) \end{bmatrix} \tag{33}$$

For efficient noise filtering, the parameter L, is chosen between $M/3$ to $M/2$. Next, an SVD of the Hankel matrix is carried out as,

$$\boldsymbol{H} = \boldsymbol{U}\boldsymbol{\Sigma}\boldsymbol{V}^H \tag{34}$$

Where, $\boldsymbol{U}$ and $\boldsymbol{V}$ are two unitary matrices containing the left and right singular vectors of $\boldsymbol{H}$ respectively and $\boldsymbol{\Sigma}$ is a diagonal matrix containing the singular values. $\boldsymbol{V}^H$ is the conjugate transpose of $\boldsymbol{V}$.

Algorithm 1 Matrix Pencil Method (with Parametric ACF) for Estimating the Parameters of A Noisy AR Signal

Input: Noisy AR signal $x(n)$; for $n = 0, 1, ..., N-1$

Output: Estimated AR parameters $\hat{a}_k$ for $k = 1, 2, ..., p$; input noise variance $\hat{\sigma}_u^2$ and observational noise variance $\hat{\sigma}_v^2$

1. Fit an AR(t) model ($t \gg p$) to $x(n)$ and calculate its parameters using the Burg method. Then calculate the impulse response $\hat{h}^{(t)}(n)$ for $n = 0, 1, ..., P$ and the parametric ACF $\hat{r}_x^{(t)}(m)$ for $m = 0, 1, ..., M$ using (39) and (40) respectively.
2. After estimating the ACF $\hat{r}_x(m)$, calculate the parameters $\hat{z}_k$ and $\hat{c}_k$ (for $k = 1, 2, ..., p$) of the exponential sum representation of $\hat{s}(m) = \hat{r}_x(m+1)\mathcal{H}(m)$ (for $m = 0, 1, 2, ..., M-1$) using the matrix pencil method.
3. Calculate the AR parameters $\hat{a}_k$ from the estimated poles $\hat{z}_k$ (for $k = 1, 2, ..., p$).
4. Estimate the ACF of the noise-free AR signal $\hat{r}_y(m)$ from (29) and use it to calculate the input noise variance $\hat{\sigma}_u^2$ using (30) and the observational noise variance $\hat{\sigma}_v^2$ using (31).

To "denoise" the Hankel matrix, the most dominant p singular values and the corresponding right singular vectors $\boldsymbol{v_1}, \boldsymbol{v_2}, ..., \boldsymbol{v_p}$ are chosen. Here, p is the number of poles of the AR system which may be known *a priori* or can be estimated at this stage from the singular values of the Hankel matrix, based on some criterion, such as the one presented in [11]. The denoised version of $\boldsymbol{V}$ is estimated from the dominant right singular vectors as

$$\boldsymbol{V}' = \begin{bmatrix} \boldsymbol{v_1} & \boldsymbol{v_2} & \dots & \boldsymbol{v_p} \end{bmatrix} \tag{35}$$

Two matrices $\boldsymbol{V}_1$ and $\boldsymbol{V}_2$ are formed from $\boldsymbol{V}'$ by deleting its last and first rows respectively. Then the poles z_k ($k = 1, 2, ..., p$) are estimated by computing the eigenvalues of the matrix

$$\boldsymbol{F} = \{\boldsymbol{V}_1^H\}^\dagger \boldsymbol{V}_2^H \tag{36}$$

Here, $\{\boldsymbol{V}_1^H\}^\dagger$ is the Moore-Penrose pseudoinverse of $\boldsymbol{V}_1^H$. Once the poles have been calculated, the coefficients c_k ($k = 1, 2, ..., p$) can be determined from the least squares solution of the overdetermined linear Vandermonde-type system

$$\begin{bmatrix} 1 & 1 & \dots & 1 \\ z_1 & z_2 & \dots & z_p \\ z_1^2 & z_2^2 & \dots & z_p^2 \\ \vdots & \vdots & \ddots & \vdots \\ z_1^{M-1} & z_2^{M-1} & \dots & z_p^{M-1} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \\ c_3 \\ \vdots \\ c_p \end{bmatrix} = \begin{bmatrix} s(0) \\ s(1) \\ s(2) \\ \vdots \\ s(M-1) \end{bmatrix} \tag{37}$$

In practice, several steps of this method can be optimized for computational efficiency as described in details in [13]. A rigorous mathematical background of the matrix pencil method can be found in [11] and [10].

C. Parametric Estimation of the Autocorrelation Function

In the previous subsections, we have described how we can estimate the parameters of the noisy AR signal from its

autocorrelation function. A common approach of estimating the ACF is

$$\hat{r}_x(m) = \frac{1}{N} \sum_{n=0}^{N-1-k} x^*(n)x(n+m); \text{ for } m = 0, 1, ..., M \tag{38}$$

We could use this estimate to form $\hat{s}(m) = \hat{r}_x(m+1)\mathcal{H}(m)$ for $m = 0, 1, ..., M-1$, which is the approach adopted in [3] and [9]. It works well for the proposed method at high SNRs as well. However, to effectively denoise the Hankel matrix at very low SNRs and to precisely calculate the poles using the matrix pencil method we need to utilize the coefficients at higher lags (at least 6 to 8 times the number of poles). But, here, this simplistic approach to estimating the ACF often falls short, because the variance of the estimated coefficients quickly increases with increasing lag. Also, it could be hard to choose the number of coefficients (M) to use for the estimation task. If choosing too few coefficients could lead to numerical instability, and choosing too many could lead to inaccurate estimation due to high variance at greater lags.

The above approach is non-parametric and thus, it does not utilize the *a priori* knowledge about nature of the noisy AR signal. We devise a more accurate approach to estimating the ACF taking the nature of the signal under consideration. An AR(p) signal with additive noise can be modeled as an AR(p)/MA(p) (Autoregressive Moving Average) signal [4]. Again, an AR(p)/MA(p) signal can be modeled as an AR signal of higher order t [12], where $t \gg p$. We exploit the fact that there exist highly efficient and numerically stable algorithms such as the Burg method for estimating AR model parameters. So, first we model the noisy AR(p) signal as a higher order (noise-free) AR(t) signal and estimate its parameters $\hat{a}_k^{(t)}, k = 1, 2, ..., t$ and $\{\hat{\sigma}_u^{(t)}\}^2$ by an efficient method such as the Burg method. Then we can iteratively calculate the impulse response of the AR(t) signal for the first P samples from the difference equation

$$\hat{h}^{(t)}(n) = \begin{cases} -\sum_{k=1}^{r} \hat{a}_k^{(t)} \hat{h}(n-k) + \delta(n) & \text{for } P > n \geq 0 \\ 0 & \text{for } n < 0 \end{cases} \tag{39}$$

Then we can calculate the parametric ACF as

$$\hat{r}_x^{(t)}(m) = \left\{\hat{\sigma}_u^{(t)}\right\}^2 \sum_{n=0}^{P-1-k} \left\{\hat{h}^{(t)}(n)\right\}^* \hat{h}^{(t)}(n+m) \quad \text{for } m = 0, 1, ..., M \tag{40}$$

In practice, we found that $t > 3p$ works well. If the impulse response decays to ignorable values within the evaluated range we can choose similar values for P and M. Otherwise $P > 2M$ works well to avoid the windowing effect.

IV. Results

In this section, we evaluate the performance of the proposed method in estimating the parameters of noisy AR signals and compare them with other methods - more specifically the high-order Yule-Walker (HOYW), iterative least squares method (ILSNP) with no prefiltering [8] and the EMD method [9]. We will present results for three AR systems with the following sets of parameters

System 1: $\mathbf{a} = [-0.8600 \;\; 1.0494 \;\; -0.6680 \;\; 0.9592 \;\; -0.7563 \;\; 0.5656]^T$

System 2: $\mathbf{a} = [-2.7607 \;\; 3.8106 \;\; -2.6535 \;\; 0.9238]^T$

System 3: $\mathbf{a} = [0.2080 \;\; -0.6749 \;\; 0.1991 \;\; 0.9238]^T$

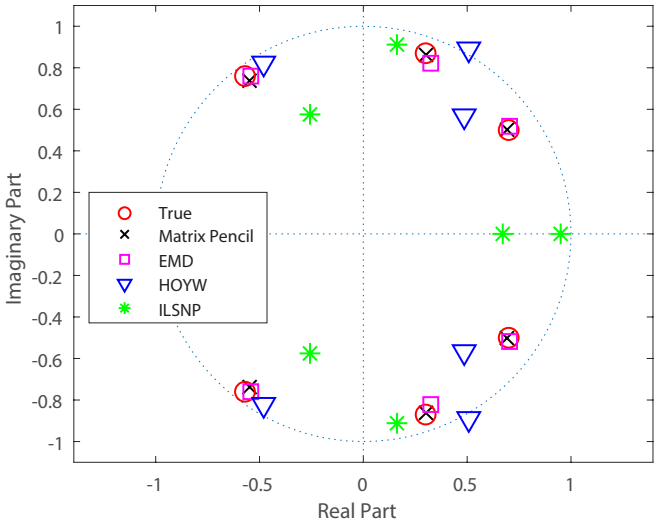

Fig. 1. Estimate of the poles of AR System 1 at SNR=-5dB by different methods

TABLE I
Performance Comparison of Different Methods for AR System 2 at SNRs of 10dB and -5dB (Under Each Estimated Parameter First SDMs and Then SDTs Are Shown)

Parameter	SNR (dB)	Proposed Method	EMD Method	ILSNP Method	HOYW Method

	-5	0.8997 ± 0.0110 ± 0.0265	0.8925 ± 0.0374 ± 0.0484	0.8257 ± 0.5394 ± 0.5416	0.9249 ± 0.1343 ± 0.1326
RMSE(%)	10	1.40	0.18	6.64	1.12
	-5	3.18	4.82	45.26	14.31

For each system, data were generated using their corresponding difference equations. In all simulations we used $N = 4000$ data samples. Observational white noise was added to the AR signals according to the SNR under consideration. The noisy AR signal was fitted to a high order $t = 32$ pole AR(t) signal for the estimation of parametric ACF. In our experiments, we evaluated both the impulse response and the parametric ACF for $P = M = 128$ samples/lags. For the formation of the Hankel matrix, $L = 32(\approx M/3)$ was used.

First, we present the estimated poles for System 1 by different methods at SNR=-5dB in Fig. 1. At this low SNR, both HOYW and ILSNP methods fail to satisfactory estimates of the poles. But both the EMD and the proposed matrix pencil method are able to estimate the poles with satisfactory accuracy, even at such low level of SNR. But unlike the EMD method, the Matrix Pencil Method is non-iterative and computationally much more efficient.

Next, we present comparative results for different methods in estimating AR parameters at SNR levels of 10dB and -5dB. The results for System 2 and 3 are presented in Table I and Table II respectively. These results were produced by running 1000 simulations of the corresponding AR systems. Under each estimated parameter, first standard deviation with respect to mean (SDM) and then standard deviation with respect to true value (SDT) are shown. For an overall measure of accuracy in estimation the root mean squared error (RMSE) of the estimates is also shown in the tables. We used the definition of RMSE given in [9].

The results presented in Table I and II show that the proposed matrix pencil based method achieves comparable results to the EMD based method, or even outperforms the EMD method at -5dB SNR. The values of SDM and SDT show that the proposed method consistently achieves accurate estimations. Thus, the results suggest that the proposed method is able to achieve accurate results while being computationally efficient and also overcomes the shortcomings of the EMD based method.

V. CONCLUSION

In this paper, a new principled approach for estimating the parameters of an AR signal with additive noise is presented. We showed that the autocorrelation function of the noisy AR system can be modeled as a non-increasing exponential sum and then utilized the matrix pencil method to estimate its poles. The use of parametric ACF facilitates accurate estimation of the correlation coefficients at greater lags which improves the accuracy and the numerical stability of the matrix pencil method at a low SNR. We presented a rigorous mathematical derivation of the proposed method and also demonstrated its effectiveness in AR parameter estimation by means of extensive simulations. The simulation results show that the proposed method is able to accurately estimate AR parameters even at very low levels of SNR.

***Abstract*—Compressive Sensing(CS) is a new prototype in signal processing. CS requires significant computations and memory spaces because whole wideband spectrum is approximated to find an opportunity for a Cognitive Radio (CR) usage. In this paper, a CR receiver wideband sensing unit is presented where a notable portion of the wideband spectrum is approximated through compressive sensing. This structure reduces computational burden and improves the detection performance. In this paper, we have presented a spectrum sensing approaches where compressive sensing will be accomplished under cooperative cognitive radio network as well as non-cooperative approach in terms of receiver operating characteristics (ROC). The investigation has been carried out under Additive White Gaussian Noise (AWGN), Rayleigh, Rician, and Nakagami channel considering the fading effect. Finally, the most appropriate arrangement for spectrum hole detection has been determined through step by step comparative analysis.**

***Index Terms*—cognitive radio, compressive sensing, cooperation, fading models, decision fusion rule.**

I. INTRODUCTION

The Radio spectrum is a limited, government-led natural resource. In accordance with the current policy, all frequency bands for a particular geographical location are completely and statistically licensed for wireless networks and each system has assigned a frequency band to them. Due to the improvement of a vast number of wireless devices, it has become a challenge because all currently under developed wireless systems are not provided with sufficient spectrum. So it is necessary to identify the available vacant frequency bands across multiple dimensions and efficiently utilize them without having interference with the Primary Users (PU)s of that spectrum. The task can be accomplished by cognitive radio which aims to detect the vacant spectrum holes with high probability of detection. Several methods are suggested for identifying the presence of primary users' signal transmissions.

The entire operation of CR relies on spectrum sensing which is the first and most important task of CR. Sensing can be performed either on narrowband or wideband levels. When there is enough information about the primary users signaling, center frequency and bandwidth, narrowband sensing can be performed.

On the other hand, wideband spectrum sensing obtains better utilization of the frequency spectrum, when the occupancy details of the primary users are unknown to cognitive network users. Conventional wideband spectrum sensing techniques are based on high sampling frequency. Because functioning at or above Nyquist rates are challenging, as it can cause more computational complexity. The design and implementation of wideband sensing systems are both difficult due to high implementation complexity and large energy consumption from high-rate analog-to-digital converters (ADC). There are numerous wideband sensing techniques that make use of sub-Nyquist sampling commonly known as Compressive Sensing (CS). Tian and Giannakis firstly introduced compressive sensing theory to sense wideband spectrum in [1]. This technique used fewer samples closer to the information rate, rather than the inverse of the bandwidth, to perform wideband spectrum sensing [2]. After reconstruction of the wideband spectrum, wavelet-based edge detection was used to detect spectral opportunities across wideband spectrum [3]. In this paper, Compressive Sensing is presented under cooperative cognitive radio network that enables the efficient operation of both the PU and the CR networks. It will be easier to get rid of the problem of multipath fading and hidden node problem if spectrum sensing is performed with the assistance of multiple CR nodes.

II. METHODOLOGY

A. Compressive Sensing

In both scholarly community and industry, Sub-Nyquist techniques are drawing more and more recognition. For the purpose of detecting spectral opportunities in the wideband, sub-Nyquist wideband sensing alludes to the procedure of obtaining wideband signals/spectrums using sampling rates lower than the Nyquist rate. Compressive Sensing (CS) is an essential type of sub-Nyquist wideband sensing. Compressive sensing is a technique that can efficiently acquire a signal using relatively few measurements, by which unique representation of the signal can be found based on the signals sparseness or compressibility in some domain [2]. The wideband spectrum is fundamentally sparse as the spectrum is poorly utilized. CS is a promising candidate for wideband spectrum sensing as it uses sub-Nyquist sampling rates. The purpose of compressive sensing is to recover signals from far fewer measurements than needed for traditional sampling.

A (ultra-)wide frequency band can be considered, where the both licensed primary communication systems and unlicensed CR networks are hosted by the band. Different from the compressed sensing scheme in [4], we consider a slotted frequency segmentation structure in which the entire wideband channel is divided into M non-overlapping narrowband sub-channels centered at $\{f_m\}_{m=0}^{M-1}$ [5]. The transmitted signals of J active primary users are considered and denoted by $s_j(t), j = 1,...,J$. The signal transmits through a wireless fading channel and

$s_j(t)$ reaches the i-th CR receiver in the form $h_{ij}(t) * s_j(t)$, where $*$ denotes convolution and $h_{ij}(t)$ is the channel impulse response [5]. The received signal at CR i is thus given by [5],

$$r_i(t) = \sum_{j=1}^{J} h_{ij}(t) * s_j(t) + w_i(t) \quad (1)$$

where the ambient noise $w_i(t)$ is white Gaussian with zero mean.The first step of compressive sampling is to collect timedomain samples [5]. To reduce the sampling burden and

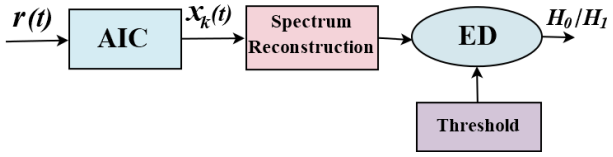

Fig. 1. Compressive Sensing by means of Analog to Information Converter (AIC)

computational complexity in the wideband regime, a hint of promising Analog to Information Converter (AIC) have illustrated for spectrum sensing architecture in Fig.1. An AIC is conceptually similar to an analog-to-digital converter (ADC) operating at Nyquist rate followed by compressive sampling which gives us the opportunity to avoid the use of high rate ADC . Therefore, this model consists of a pseudo-random number generator, a mixer, an accumulator and a low-rate sampler. The pseudo-random number generator produces a discrete-time sequence that extracts information from the modulated signal $r(t)$ by a mixer. The accumulator is used to sum the demodulated signal, while a low rate sampler is utilized to sample its output signal. After that, it is necessary to reconstruct the sparse signal which can be directly accomplished from partial measurements using CS algorithms. Let the output of the AIC is sampled signal of received signal,$r(t)$, denoted by r_k,

$$r_k = [r_{kM}, r_{kM+1}.....r_{kM+M-1}] \qquad k = 0,1..K \quad (2)$$

r_k is the time domain representation of $r(t)$, and is a $M \times 1$ vectors. The size of the measurement matrix Φ_A is $M \times N$, such that,

$$x_k = \Phi_A r_k \quad (3)$$

Here $N < M$ and measurement matrix Φ_A is a set of basis function used to collect the time domain sample from the received signal. It amounts to collect samples on the Nyquist grid but skipping randomly $(M-N)$ time instants to reduce the average sampling rate [5]. Hence, output of the AIC denoted by the size of $N \times 1$ vectors,

$$x_k = [x_{kN}, x_{kN+1}.....x_{kN+N-1}] \qquad k = 0,1..K \quad (4)$$

Now we need to estimate the spectrum of the received signal for energy detection (ED).Eventually, recovery of the compressive sampling can be done by solving l_1 norm optimization problem [6]- [7] which is based on basis pursuit algorithm [8].

For energy detection(ED) scheme, the energy of the reconstructed spectrum of received signal will be compared with a threshold, measured by Gamma Inverse Function [9]. The task of spectrum sensing is the following binary hypothesis-testing problem [10]:
H_0 : primary user is absent;
H_1 : primary user is present.

B. Cooperative Spectrum Sensing

When multiple CRs cooperate with each other in a network for the purpose of spectrum sensing, the process is called cooperative sensing. Fig. 2 illustrates a system model where compressive sensing is established for cooperative network. In a cognitive radio network (CRN), every cognitive node

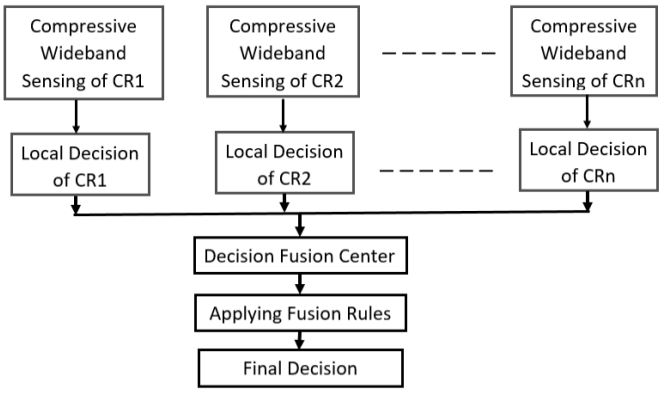

Fig. 2. System Model for Compressive Sensing in Cooperative Network

separately performs compressive spectrum sensing utilizing energy detection scheme. Then to settle the conclusion they sends the local decision (binary or decision statistic) through control channel to the common receiver called Decision Fusion Center. The received spectrum at individual CR is compared with a predetermined threshold value to construct the local decision. In order to minimize the controll channel overhead, CRs only share their final 1-bit hard decisions (H_0 or H_1) rather than their decision statistics [10]. A cognitive manager (CM) or decision fusion center is accountable for collecting the local sensing decisions from all the member nodes presented in a CRN. Then the local decisions are fused and combined by employing different fusion rules. Thus the final decision made by the fusion center will enhance the detection performance in a cooperative CRN. We have applied four decision fusion rules at Fusion Center:

1) AND-rule: In this rule, if all of the local decisions sent to the decision maker are one, the final decision made by the decision maker is one [11]. The fusion centers decision is calculated by logic AND of the received hard decision statistics. For simulation, we have used the following formula for AND-rule [11]:

$$P_{d,AND} = P_{d,i}^{N} \quad (5)$$

Where $P_{d,i}$ is the probability of detection for i-th CR node and N is the total number of CR nodes.

2) OR-rule: In this rule, if any one of the local decisions sent to the decision maker is a logical one, the final decision made by the decision maker is one [11]. For simulation, we have used the following formula for OR-rule [11]:

$$P_{d,OR} = 1 - \Sigma(1 - P_{d,i})^N \tag{6}$$

3) Majority-rule: In this rule, if half or more of the local decisions sent to the decision maker are one the final decision made by the decision maker is one [11].The following formula from [11] describes the rule:

$$P_{d,MAJ} = \sum_{l=\lfloor N/2 \rfloor}^{N} \binom{N}{l} P_{d,i}^{l}(1 - P_{d,i})^{N-l} \tag{7}$$

Here $\lfloor . \rfloor$ represents floor operator. In mathematics and computer science, the floor function maps a real number to the greatest preceding or the least succeeding integer, respectively. More precisely, $floor(x) = \lfloor x \rfloor$ is the greatest integer less than or equal to x.

4) Optimal Fusion rule: Though the logical operations can provide a satisfactory performance in many practical scenario but the optimality of the fusion is not guaranteed. The optimal fusion (OF) rule comes out which is employed by the following likelihood ratio test [12]:

$$\Lambda = \sum_{i=1}^{n} [u_i \log \frac{P_{di}}{P_{fi}} + (1 - u_i) \log \frac{1 - P_{di}}{1 - P_{fi}}] + \log \frac{P(H_1)}{P(H_0)} \tag{8}$$

Where P_{fi} is the probability of false alarm for i-th CR node and when $\Lambda \geq 0$, then the Primary User is present; otherwise, Decision Maker decides the absence of Primary Users. In line with optimal fusion rule or simply optimum rule, we can set a weighted value for each CR node depending on the distance between cognitive radio user and PU. The weight of a node determines the priority of its decision to affect the final one. The highest priority goes to the CR user which is more near to the PU than other CR user.

C. Fading Models

Fading models are used to reduce the fading effect and improve the performance of the communication channel. The additive white Gaussian noise (AWGN) is a fundamental commotion used in information hypothesis to emulate the impact of numerous irregular procedures that happen in nature. AWGN channel model is characterized by the linear addition of white noise with a constant spectral density and a Gaussian distribution of amplitude. The model does not represent blurring, frequency selectivity, obstruction, non-linearity or scattering. Rayleigh fading channel is introduced where signal is received from multipath. When the impulse response is modeled as a zero mean complex-valued Gaussian process, the channel is characterized as a Rayleigh fading channel [13]. The main difference between the model of Rayleigh fading and Rician fading is that in Rician fading a predominant segment is present. Rician K-factor has been used in the simulation which is defined as the ratio of signal power in dominant component over the (local-mean) scattered power [13]. The Nakagami distribution matches some data which is verifiable by observation or experience rather than theory or pure logic, which makes it superior to other models. Nakagami parameter, m is used to model signal for excessive to mild fading issue. If the signal amplitude follows m, a gamma distribution is followed by the PDF [14].

III. System Model Simulation & Performance Analysis

In this section, a simulation study is performed to validate the analytical results. First we examine the single user case, subsequently we consider cooperative sensing. We consider, at baseband, the wideband signal is in the range of $[1 - 64]$ MHz, that is partitioned into M = 32 equal-bandwidth sub-channels of 2 MHz. In this section, simulations are performed along with the description of obtained graphical layouts which are acquired during the sensing of primary user signals applying compressive sensing scheme and different decision fusion rules in cooperation. Results are compared between different fading channels. All simulations in this work is executed using MATLAB version R2016a. Monte Carlo (MC) method, is a stochastic technique (based on the use of random numbers) which forms the basis of these simulations. BPSK modulated signal has been applied in the spectrum sensing method for different fading channel (AWGN,Rayleigh,Rician,Nakagami). The detection performance is analyzed based on the Receiver Operating Characteristic (ROC) curve. ROC curve is a fundamental plot in signal detection theory where the advantage of ROC curve is utilized to capture all the aspects of signal detection theory in one graph.

At first the performances of different fusion rules should

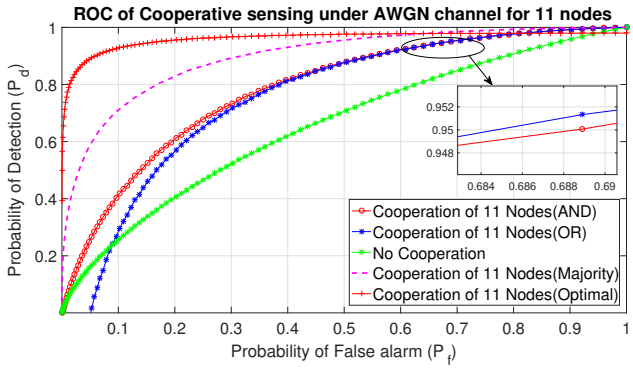

Fig. 3. Comparison of different fusion rules under AWGN channel

be compared employing a specific fading channel. The ROC curves for the decision fusion rules (AND, OR, Majority, Optimal Fusion) under AWGN channel has been shown in

Fig.3 for 100000 Monte-Carlo simulation. The figure indicates that the performance of cooperation process (11 nodes) is more improved than the non-cooperative one, because probability of false alarm may rise due to some hidden node problem when primary user's transmitted signal could not be detected by one node because of the location of the node. But whenever a number of nodes (11 nodes in this case) cooperate their detection result the probability of detection become higher than the probability of false alarm and thus cognitive radio device can avoid unwanted interference to the primary user (PU). For more better detection and less interference it is needed to compare different fusion rules under definite fading or non-fading channel. The application of AND rule under AWGN channel enhances the probability of detection in the region where probability of detection, P_d increases more rapidly than probability of false alarm, P_f. In this case, there is the possibility of causing interference with PU is the least as the presence of PU can be detected by all of the nodes. However, in the region where P_d increases less rapidly than P_f, OR-rule surpasses the ROC of AND-rule which can be observed from the zoomed part of the figure. It can be said that the region where the probability of false alarm become higher gradually, the OR-rule gives better detection performance than AND-rule as the presence of PU can be detected by any one of the nodes. The detection performance by application of majority-rule is superior to both the AND-rule & OR-rule because the PU detection depends on the greater part of the cooperative nodes. Cooperative sensing for Optimal Fusion rule provides a very sharp and abrupt curve as illustrated in the figure which indicates that the probability of detection is higher for a lower probability of false alarm. It is known that a higher value for P_d and a lower value for P_f is desirable at the same time for effective spectrum sensing. Therefore, it can be said that the optimal fusion rule offers the best performance among the four fusion rules under AWGN channel. But in the case, when we did not know the distance between primary user and cognitive radio user we should prefer majority rule for cooperation.

The ROC curves for the decision fusion rules (AND, OR, Majority, Optimal Fusion) under Rayleigh channel has been shown in Fig.4 for 100000 Monte-Carlo simulation. The ROC curve of majority-rule deviates more than the ROC curves of the other three rules. The region of high threshold value, the ROC curve of the majority rule is superior than the ROC curve of AND-rule and OR-rule momentarily. After a while, the ROC curve of AND-rule & OR-rule, become superior than the ROC curve of the majority rule, when the threshold value decreases and P_f rises. However, in the region where P_d increases less rapidly than P_f, OR-rule surpasses the ROC of AND-rule which can be observed from the zoomed part of the figure. It can be said that in that region, the OR-rule gives better detection performance than AND-rule as the presence of PU can be detected by any local decision received by the Fusion Center. Cooperation done by Optimal Fusion rule provides a very sharp and abrupt curve as illustrated in the figure which indicates that the probability of detection is higher for a lower probability of false alarm. Therefore, the optimal fusion rule presents the greatest performance among the four fusion rules under Rayleigh channel.

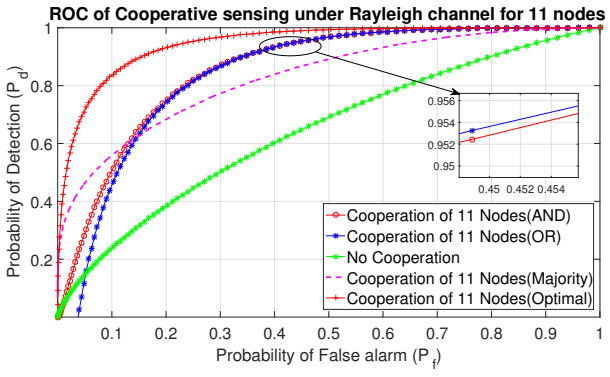

Fig. 4. Comparison of different fusion rules under Rayleigh channel

The ROC curves for the decision fusion rules (AND, OR, Majority, Optimal Fusion) under Rician channel has been shown in Fig.5 for 100000 Monte-Carlo simulation. The Rice factor (k) has been set as 2 in case of cooperative spectrum sensing. Among the four rules, optimal fusion rule performs the best detection performance while the performance reduction is most noticeable for OR-rule according to the analysis. The performance of majority rule is inferior than optimal fusion rule but superior than AND operation & OR operation. The ROC of AND-rule surpasses the ROC of OR-rule because AND-rule gives better detection performance here. However, in the region where P_d increases less rapidly than P_f, OR-rule surpasses the ROC of AND-rule which can be observed from the zoomed part of the figure. The ROC curve rises almost linearly for the non-cooperative Compressive Sensing approach. Cooperative approach has analyzed for 11 CR nodes.

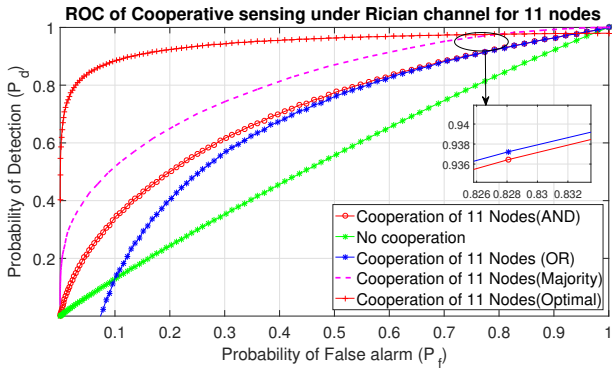

Fig. 5. Comparison of different fusion rules under Rician channel

The ROC curves for the decision fusion rules (AND, OR, Majority, Optimal Fusion) under Nakagami channel has been shown in Fig.6 for 100000 Monte-Carlo simulation. The Nakagami model represents an analytical evaluation where Nakagami distribution, m is applied for analysis of fading data. The Nakagami distribution (m) has been considered as

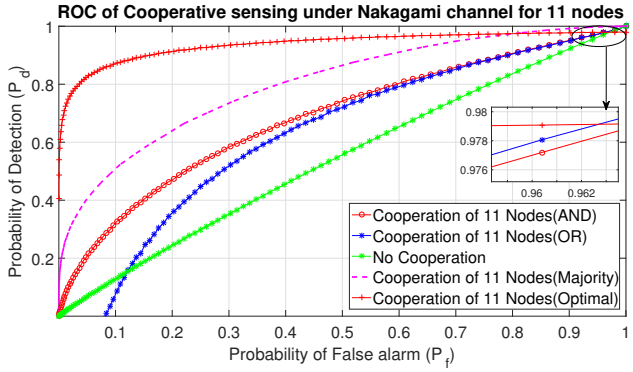

Fig. 6. Comparison of different fusion rules under Nakagami channel

unity. The figure indicates that using the optimal fusion rule provides better detection than the other rules under Nakagami fading effect. The reason behind it is that when it is used, the cooperation is performed based on the weighted value of the CR nodes. The performance of OR-rule reduces the most, yet the majority-rule offers better performance than other non-cooperation approaches, AND-rule, and OR-rule. However, in the region where probability of false alarm rises, logic operation OR surpasses the ROC of logic operation AND which can be observed from the zoomed part of the figure.

The ROC curves for different channel (AWGN, Rayleigh,

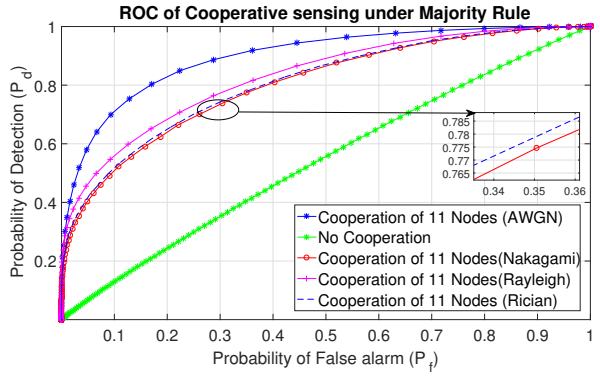

Fig. 7. Cooperation using Majority-rule under different fading channels

Rician, Nakagami) under majority rule has been shown in Fig.7 for 100000 Monte-Carlo simulation. When the cooperation of 11 nodes is done in non-fading AWGN it shows the best performance as indicated in the figure. For Rayleigh channel, the P_d is lower in comparison with the AWGN channel because of the multi-path fading characteristics of the Rayleigh channel. In this figure, the performance of cooperative sensing in Rician channel is more inferior than Rayleigh fading channel & superior than Nakagami fading channel. The ROC curve of majority-rule for Nakagami channel deviates more than the ROC curves of majority-rule for the other two fading channels. Hence for Nakagami fading channel, the performance of cooperative sensing degrades mostly than other two fading channels, due to rapid fading effects. The Nakagami distribution (m) has been considered as unity.

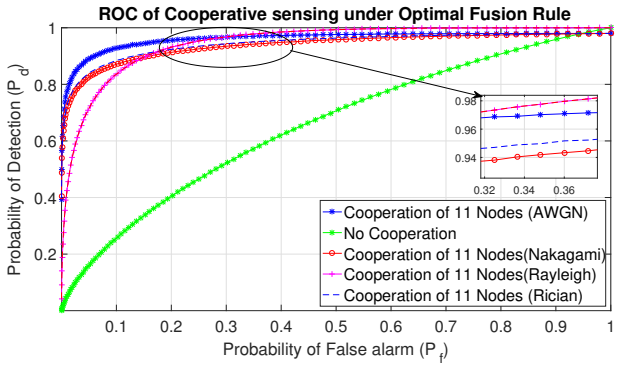

Fig. 8. Cooperation using Optimal Fusion-rule under different fading channels

Now we need to know for more effective spectrum sensing which fading model will be appropriate for optimal fusion rule, which has the most superior performance than the other three fusion rules. The ROC curves for different channel (AWGN, Rayleigh, Rician, Nakagami) under optimal fusion rule has been shown in Fig.8 for 100000 Monte-Carlo simulation. When the cooperation is done in non-fading AWGN it shows the best performance as indicated in the figure. From the figure comparing with the Rician fading channel, the performance degrades more under Nakagami channel, although optimal fusion rule provides almost equal performance under both fading channel. At the region where P_d increases more rapidly than P_f, the performance of Rayleigh fading channel is inferior than the performance of Rician & Nakagami channel momentarily. After a while, as the value of P_f rises gradually, the performance of Rayleigh channel become superior than the other two fading channel which can be observed from the zoomed part of the figure. The Rayleigh fading channel, is suitable for transmission in the absence of Line of Sight (LoS) between the transmitter and the receiver due to multi-path fading. Whereas Rician channel provides a strong dominant Line of Sight component & Nakagami channel characterizes rapid fading. Therefore, it can be said that, for non-fading case, cooperative approach using optimal fusion rule under AWGN channel is preferable. But for fading case, Rayleigh channel is the optimum condition for spectrum sensing in CR network.

IV. Conclusion

Spectrum sensing performed by a stand-alone CR is critical and challenging while dealing with multi-path fading and hidden node problems and reliability of performance is questionable. Thus, cooperative spectrum sensing is introduced to get reliable detection performance as well as to minimize the interference to PUs and in consequence, the false alarm probability is reduced. We have studied cooperative spectrum

sensing over non-fading and different fading channels in CR and compared among them. It has been found that probability of detection is increased by using different fusion rules for cooperation which can reduce hidden node problem. It's been also observed that the Optimal Fusion rule has better performance than AND, OR and MAJORITY rule. After Optimal Fusion rule, the priority goes to MAJORITY rule for co-operation due to the limitation of Optimal Fusion rule where distance between primary user and cognitive radio user is needed to be known. It's also observed that spectrum sensing is harder in presence of Nakagami fading channel and performance of detection reduces more in Nakagami channel than other fading channel. Comparing different channels it can be said that best detection performance can be achieved under non-fading AWGN channel. But a communication channel generally experiences fading as transmitted signal cross a different path to reach to receiver due to presence of reflection in the environment. Therefore, for effective spectrum sensing the next priority goes to Rayleigh fading channel according to the analysis. The output signals were simulated successfully and their characteristics were recognized. Their cooperation performance were analyzed based on the several decision fusion rules in the presence of AWGN, Rayleigh, Rician and Nakagami fading. At the end, the compressive sensing played a vital role to improve the sensing performances by cooperation. In future, the analysis of throughput and the computational burden can also be performed as a part of performance analysis of Compressive Sensing in cooperative network.

***Abstract*—A novel methodology of brain controlled intelligent wheelchair by using color stimuli is proposed here. A general methodology is applied to find out most effective rhythm for color classification. Primary colors RGB and secondary color yellow were chosen for left, right, forward and stop command. Alpha, Beta, Theta, Delta rhythms were analyzed for three different subjects. Using dissimilar features of time and frequency domain twelve artificial neural network were built to decide the best rhythm. Principal component analysis was made for each EEG signal to remove the background effect of color stimuli. Comparing the findings it is visualized that beta rhythm is the most efficient rhythm with minimum mean square error of 4.845×10^{-9} among all designed ANN for color classification.**

Keywords— Electroencephalogram (EEG), Principal component analysis (PCA), Rhythm, Color stimuli, Artificial Neural Network (ANN).

I. INTRODUCTION

About hundred billion neurons are in human brain. Thoughts and emotional states makes interaction among these neurons. As a result different amplitude and frequency based EEG are produced. There are five rhythms namely alpha, beta, delta, theta and gamma [1]. Their frequency is eight to thirteen, thirteen to thirty, one to four, four to eight and thirty six to forty four Hz respectively.

Researches are going on to make an efficient and effective intelligent wheel chair for Quadriplegic and paralyzed patients. Most of recent works are based on eye blink such as described in [2]. Eye blinking is a natural phenomenon and uncomfortable command feature. By using one and two eye blink and attention level, a BCI was developed. Attention and eye blinks were also used in [3] but they have made it wireless and interfaced with RS-232C. SSVEP based wheelchair control is analyzed in [4]. Eye blink based another work is discussed in [5]. However an eye blinking pattern was used by them. An cost effective automated wheelchair with using conventional eye blinking feature is discussed in [6]. By recognizing eye movement such as blinking, glancing, eye opening a model is discussed in [7]. Researches on the basis of steady state visual evoked potential with different flickering frequency showed up good performance [8]. For classification support vector machine was used with satisfactory result.

In most of the cases either eye blinking feature or EEG raw signal was used. Some used internet of things. But there is lack of effectiveness. An innovative approach by using color stimuli is used here. To remove the background effect of the color stimuli the acquired EEG signals were gone through principal component analysis. Later band analysis was done. Though this work is depended on color stimuli but it can introduce more command features.

This paper presents a methodology to drive an EEG based wheelchair by using color stimuli with most effective rhythm. The primary colors red, green, blue were used for direction command (left/right/forward). A secondary color yellow was used to pause. The data acquisition was done by BIOPAC and Acqknowledge 4.1 software [9]. PCA and attribute extraction was done. Artificial neural network were built for classification in MATLAB 2014a.

The following portion of this article is designed as follows: part II describes about suggested method, section III describes about analyzing, section IV and V represents data analysis and classification. It ends with a opinion and coming up scope in portion VI.

II. PROPOSED MODEL

A. Projected Model

For designing EEG based wheel chair by color stimuli with PCA feature the model is described in Fig. 1. After getting the brain signal by BIOPAC and MP 36 , noise and artifact were removed. The rhythms were obtained by FIR band pass filter. To remove background effect of the color stimuli principal component analysis was done by Acqknowledge 4.1 software. The features were also extracted in this platform. Total twenty features were extracted in different frequency bands. Comparing the mean square error of artificial neural network which were based on extracted features a decision is taken about the proposed model efficiency and most effective rhythm.

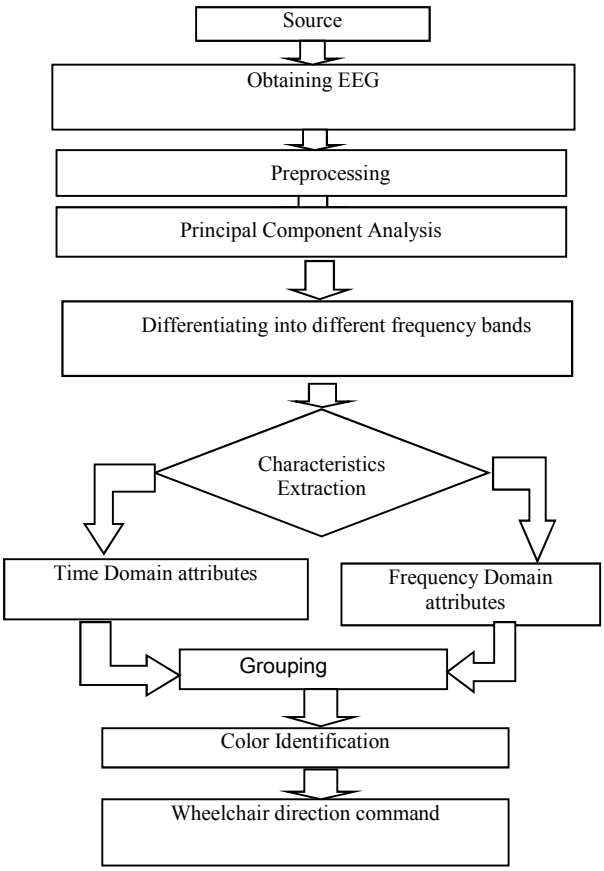

Fig. 1. Flow chart of suggested scheme

A. *Electroencephalography Determination and Exploratory Condition*

The test was conducted in Biomedical Engineering Lab of Khulna University of Engineering & Technology, Bangladesh. The test was conducted on three subjects, not suffering from any psychological disease or color blindness. The color stimuli was shown in personal computer monitor and instructed to focus on indefinite color. In real life patients may focus on monitor or colored board. Total ten trials were taken. First nine trials were used for training and validation purposes and the rest for test purpose.

B. *Experimental arrangement*

1) *Hardware description*: The BIOPAC data acquisition unit MP 36 was used in this experiment. Fig. 2 defines acquiring of EEG while conducting the experiment

2) *Diagonistic software*: Varioud softwares like BIOPAC student Lab Pro was used. For PCA and feature extractaion Acqknowledge 4.1 software was utilized. Principal component analysis was neceassry for removing background effect as the obtianed raw data was so much noisy. Artificial neural network was used in MATLAB 2014a platform.

Fig. 2. Representational view while conducting experiment in BME lab, KUET

III. PREPROCESSING AND ANALYSIS

A. *Filtering , Artifact seperating, smoothing*

The raw electroencephalogram was saved while experiment. There was noise may be due to EMG, EOG, hand movement, background effect of color stimuli. As 0.5 Hz to 44 Hz only necessary, band pass FIR filter was used. The line frequency (50 Hz) was removed. Smoothing was done for averaging the signal values.

B. *Principal Component Analysis*

Source is decomposed to a new signal by PCA. It is very effective as a data reduction tool. As the raw data was so much noisy although after removing artifact it was hard to classify individual color. So PCA was made for better color classification.

C. *Frequency bands analysis*

After filtering, smoothing, principal component analysis EEG was split up in different frequency bands by Acqknowledge 4.1 software. FIR band pass filter was used.

D. *Feature Extraction*

In time and frequency domain total twenty features were extracted. Maximum value, standard deviation, skew, kurtosis, Linear regression, moment of order from one to five, Lyapunov exponent, mutual information, correlate, Nonlinear model, power spectrum density mean , PSD max, PSD skew, fast Fourier transform mean, FFT max, FFT skew were extracted for three subjects in alpha, beta, delta, theta rhythms. All attributes were extracted in Acqknowledge 4.1 software.

IV. ATTAINED DATA

A. *Contrast of attributes of a individual rhythm for an individual color*

In time and frequency domain total twenty attributes were analyzed. In frequency domain PSD mean, PSD max, PSD skew , FFT mean , FFT max, FFT skew were analyzed. These attributes of subject 1 beta band for blue color is given in Table I.

TABLE I. RESPONSE OF BETA BAND IN FREQUENCY DOMAIN OF SUBJECT 1 FOR BLUE COLOR.

Trial	PSD (μV^2)/Hz			FFT(μV)		
	Mean	*Max.*	*Skew*	*Mean*	*Max*	*Skew*
1	0.038	0.748	4.085	0.016	0.341	4.024
2	0.038	0.769	4.185	0.017	-8.160	1.260
3	0.044	0.700	3.342	0.017	0.315	3.601
4	0.042	0.622	3.400	0.019	0.338	3.639

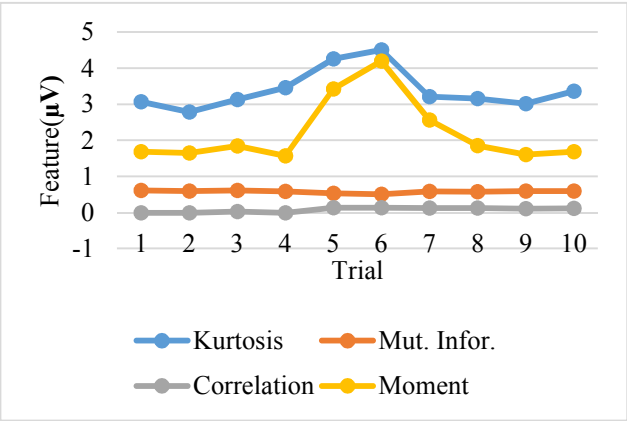

Fig. 3. Different attributes of beta band of subject 2 for red color.

Fig. 3 shows features of beta rhythm of subject 2 for red color. The kurtosis, mutual information, correlation, moment varied very small for same color and subject. Similarly twenty features were obtained for red, yellow, green, blue color and alpha, beta, delta, theta rhythm.

B. *Contrast of attributes of definite rhythm for various color*

There were three subjects and instructed at same condition. After PCA raw EEG was separated in frequency bands. Twenty features for each rhythm and every color were extracted. Fig. 4 shows PSD mean value of subject 1 of beta rhythm for different colors. For different colors the features varied greater comparatively.

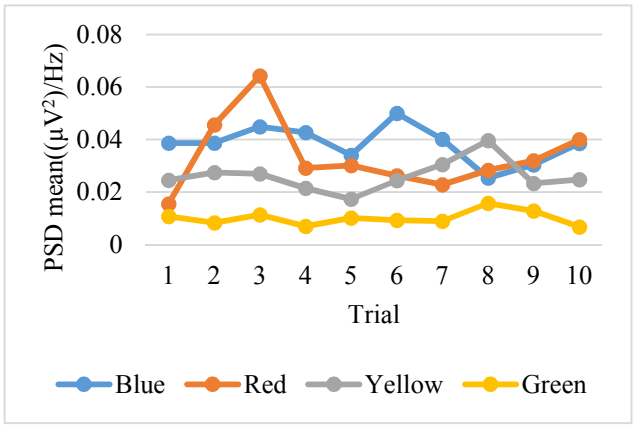

Fig. 4. Comaprison of PSD mean of subject 1 using beta rhythm for different colors

V. CLASSIFICATION RESULTS AND DISCUSSION

The categorization was required for analyzing the effectiveness of color classifying so that individual command can be identified. Moreover the effectiveness of rhythm also analyzed. By comparing the results of ANN most effective rhythm for color classification as well as command detection is determined. MATLAB built in nntool GUI was used. Feed forward backprob. , TRAINLM training function, LEARNGDM adaption learning function, two layer of Tan-Sigmoid transfer function, twenty neurons, Levenberg Marquardt learning algorithm were used. The target value was 10,20,30,40 for blue, red, yellow, green respectively.

A. *Scenario 1: Alpha Rhythm*

The ANN designed for alpha rhythm was successful to classify the colors having mean square error of 4.845×10^{-9} , regression of 0.98157 , gradient of 5.889×10^{-4} . This ANN showed worst performance.

B. *Scenario 2: Theta Rhythm*

The ANN designed for theta rhythm was able to classify colors as well as command with mean square error of 1.1028×10^{-7}, regression of 0.996 , gradient of 1.10731×10^{-3} . It showed better performance than previous.

C. *Scenario 3: Delta Rhythm*

The ANN designed for delta rhythm was able to classify colors as well as command with mean square error of 3.56×10^{-9} , regression of 0.94164, gradient of 1.2478×10^{-5}. Relatively better performance obtained.

D. Scenario 4: Beta Rhythm

The ANN designed for beta rhythm was able to classify colors as well as command with mean square error of 4.845×10^{-9} , regression of 0.98157, gradient of 5.889×10^{-4}. It showed the best performance. Performance of the ANN designed for beta rhythm of subject 1 is shown in Fig. 5.

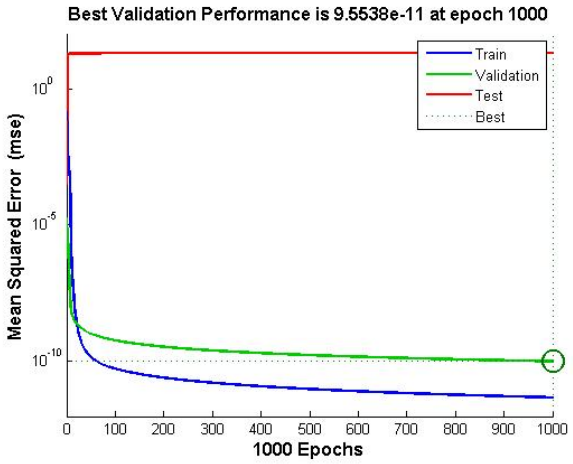

Fig. 5. Performance of ANN designed for Beta rhythm of subject 1

TABLE II . COMPARISON OF TWELVE DESIGNED NEURAL NETWORK.

Rhythm	Subject	Mean Square Error	Overall Regression	Gradient
Beta	1	9.5538×10^{-11}	0.9887	1.0290×10^{-6}
	2	1.4438×10^{-8}	0.9560	0.0017657
	3	1.5100×10^{-12}	1	4.1267×10^{-10}
	Average	4.8450×10^{-9}	0.9815	5.8890×10^{-4}
Delta	1	8.4434×10^{-9}	0.9997	2.0042×10^{-6}
	2	2.2354×10^{-9}	0.8260	1.2010×10^{-5}
	3	1.7720×10^{-12}	0.9991	2.3422×10^{-5}
	Average	3.5600×10^{-9}	0.9416	1.2478×10^{-5}
Theta	1	2.4561×10^{-7}	0.9999	0.0029
	2	5.9513×10^{-8}	0.9989	2.5050×10^{-5}
	3	2.5746×10^{-8}	0.9896	0.0003
	Average	1.1028×10^{-7}	0.9960	1.1073×10^{-3}
Alpha	1	5.6423×10^{-7}	0.9768	0.0518
	2	1.3553×10^{-5}	0.9938	0.1130
	3	3.2050×10^{-7}	0.9990	0.0227
	Average	4.8125×10^{-6}	0.9898	0.0625

All the findings of each designed neural network are showed in Table II. As total twelve ANN were built and there were three subjects so results of ANN for all subjects for same rhythm were calculated to an average value for generalization. The overall accuracy for color classification of Beta, Delta, Theta, Alpha rhythm based ANN were 100%, 99.8%,96.3% and 95% respectively. Data obtained in this work showed best accuracy for color classification as well as command for direction of wheel chair movement with Beta rhythm. Delta rhythms showed better performance and alpha rhythm showed worst performance.

VI. Conclusion

From this offline analysis of brain wave for the improvement of brain controlled wheel chair by using color stimuli, it is crystal clear that color stimuli can be used for this purpose effectively. The beta rhythm provided best performance for color classification of individual with minimum mean square error of 4.845×10^{-9} . Contradictory alpha rhythm showed worst performance with mean square error of 4.81257×10^{-6} .This method is more effective than conventional eye blinking based model because the command feature can be increased with increase in number of color stimuli. The feature of rotation at a certain angle, forward, backward, pause,left, right can be introduced through this proposed method. However there is a drawback of this proposed method is subject's visual weakness. The efficiency can be increased with increase in number of channels.

The future work can be implementation of this method with an increased number of color stimuli and channel. Making a fast online analysis system of EEG is under progress.

***Abstract*—Due to the inferior quality of image capturing devices and acute environmental condition, digital images may suffer from poor contrast. Several histogram equalizing methods have been proposed to enhance these images but most of them either create over enhancement with artifacts or cannot fulfill consumers' desired contrast. However, due to having improper handling of the pixels, histogram equalization (HE) based techniques often fail. Hence, a new image enhancement approach has been introduced here named as Mode-Separate Histogram Equalization (MSHE) which finds a separation point using most frequent intensity of an image and afterwards HE is applied. In experiments qualitative and quantitative assessments exhibits that the performance of MSHE is better than other contrast enhancement with brightness preservation techniques.**

***Index Terms*—Contrast enhancement, Histogram equalization, Brightness preservation**

I. Introduction

Digital images often suffer from low contrast due to the poor quality of image capturing device, light variation, surface reflection and so on. In that case, it demands the process of contrast enhancement, brightness preservation, image correction by denoising and sharpness enhancement. For making a good quality image, several methods have been already proposed. Of those, Histogram Equalization (HE) is most widely used technique [1]. In spite of its popularity, it fails to preserve mean brightness and causes over enhancement at times. To overcome this problem, Brightness preserving Bi-Histogram Equalization (BBHE) proposes mean intensity of an image to separate the histogram [2], whereas Dualistic Sub Image Histogram Equalization (DSIHE) uses median for partitioning the histogram [3]. Meanwhile, Bilateral Histogram Equalization with Pre-processing (BHEP) uses harmonic mean [9] and Minimum Mean Brightness Error Bi-histogram Equalization (MMBEBHE) computes a threshold based on absolute mean brightness error to separate the histogram [8]. However, these mean based histogram separation techniques fail for different kind of images, for example BBHE doesn't work well when there is no symmetrical distribution and DSIHE sometimes causes over enhancement due to an outlier. For dark images, BHEP fails to enhance the contrast. Again computational complexity for MMBEBHE is very large.

To mitigate above mentioned problems several recursively separated histogram equalization based techniques have been proposed. Among those, Recursive Mean Separate Histogram Equalization (RMSHE) uses the mean to separate the histogram recursively [4] and Recursive Sub Image Histogram Equalization (RSIHE) considers the median value for the same [5]. Recursively Separated and Weighted Histogram Equalization (RSWHE) uses both mean and median value to separate the histogram recursively and additionally it modifies the probability density function *(pdf)* to use as a normalized power law function [6]. Though brightness is preserved more in these recursion techniques, larger recursion level means no enhancement, output image is same as the input image. To mitigate these problems, it is essential to give answer of the following research questions.

- How to separate histogram for making equal distribution?
  To separate histogram, the most frequent intensity of an image with a weighting factor can be proposed.
- How the intensities can be spreaded all over the intensity range?
  For spreading the intensities histogram equalization should be applied over the sub parts. And finally these two sub parts are merged to get the desired one.

The rest of this paper is organized as follows. Section 2 presents an overview of the existing works while Section 3 presents proposed solution. Section 4 demonstrates the efficacy of the proposed algorithm and other existing methods. Finally, Section 5 concludes the findings and future remarks.

II. Literature Review

As contrast enhancement is a crucial demnad, different methods have already been proposed. HE enhances the contrast by flattening histogram distribution of an image [1]. However, HE creates over enhancement and causes mean shift problem. Different extensions of HE exists for enhancing image contrast mostly based on mean, median of the image. Details are being discussed in the following.

The first mean separation technique proposed by Kim et al. titled as BBHE where an input image histogram is decomposed into two based on their mean [2]. Then HE is applied over two parts individually and combined into one single image. BBHE works well when the input image follows symmetric distribution but it fails to perform well when input images have non-symmetric distribution [9].

Another algorithm that uses mean as the criterion for histogram division is RMSHE, proposed by Chen et al., is a generalization of both HE and BBHE [4]. RMSHE is proposed to separate the histogram recursively and it produces 2^r number of sub histograms where recursion level *r* is specified by the user. Although this algorithm preserves more brightness, it produces some side effects too. Again if the value of *r* is too large, the output image is same as the input image [22].

Chen et al. propose to use absolute difference between input and output image mean to decide a threshold level in MMBEBHE [8]. A threshold for the lowest absolute mean brightness error (AMBE) is selected and using this input image is separated into two and equalized individually as in BBHE. Nevertheless, the repetitive calculation of AMBE creates large computational complexity [6].

Harmonic mean is also used in BHEP, proposed by Amil et al. [9], which sharpens input image to get the edges correctly using high boost filter and divides image histogram using harmonic mean. After combining the sub images into one image, it is smoothed using Gaussian filter to remove the extremely sharp edges. This technique may not enhance the contrast for dark images [15].

Another extension of histogram equalizing technique is median based. First image median to separate histogram is used in DSIHE, proposed by Wang et al. [3]. Although DSIHE does not shift the input mean, sometimes it fails to preserve original image mean brightness. At times it creates over enhancement problem because in an image the median value can be a high peak or impulse noise [26].

RSIHE is proposed by Sim et al. which also uses median recursively as the separating factor [5]. The sub images will be decomposed, if the recursion level *r* is specified as *2*. Although RSIHE performs better than RMSHE, it also faces the same problem as RMSHE when the value of *r* is too large [23].

Kim et al. propose RSWHE which uses both mean and median image intensity to separate histogram recursively [6], similar to RMSHE and RSIHE. It also introduces histogram weighting module which smooths the sub histograms using normalized power law function. However, statistical information might lose and quality can be degraded [7].

Besides these histogram equalizing algorithms, some techniques such as adaptive gamma correction with weighting distribution (AGCWD) and adaptive gamma correction for image enhancement (AGC) follow gamma correction. AGCWD overcomes the problem happening in RSWHE where cumulative distribution function (*cdf*) is directly utilized for setting up the parameter [7]. AGCWD works well except when input images having a lack of bright pixels, then enhancement may not be like as desired [19]. Rahman et al. propose AGC which also uses gamma correction where images are classified into four classes based on their mean and standard deviation [14]. Although AGC works well for almost all kind of images, for some high contrast images it needs further improvements increasing the gamma value [21]. Again this method can not preserve edge details of original image [20].

Focusing on low contrast images Celik et al. propose an algorithm named as Contextual and Variational Contrast Enhancement (CVC) which increases the gray level differences between neighboring pixels [11]. 2-D input image histogram is constructed here, so the computational complexity of this algorithm becomes larger [7].

Layered Difference Representation (LDR) is proposed by Lee et al., considers full dynamic range of an input image to improve contrast [12]. Unfortunately, LDR treats all the pixels equally where foreground pixels should be given more importance [24].

Tsai et al. propose decision tree-based contrast enhancement for various color images where luminance variance and mean are used to classify input image into six groups [13]. Then image enhancement is done based on the peak and valleys, and piece wise linear transformation function is applied. The predefined values might not work well in all the cases [14].

Using a local transformation method Hussain et al. propose histogram specification technique for dark images, which applies a sobel operator to separate edges and non edges and computes histograms for both [15]. Segments are found and used to have two target histograms which are lastly merged to get one; that is used in the histogram specification technique to enhance the whole image. It fails for bright images and create artifacts in the bright regions [27].

From the above discussion, it is found that among the existing image enhancement algorithms, histogram equalizing methods show superior outcome compare to others for low contrast images. Separating histogram and applying HE on both sub parts is the main idea of HE based techniques. However, dividing the histogram imprecisely is a major reason of failure to enhance the image for these techniques. Therefore, for improving low contrast images, accurate separation of histogram is required in HE oriented algorithms.

III. Proposed method

The main objective of this paper is to transform low contrast image into a visually pleasant one by enhancing its contrast. Hence, a Mode-Separate Histogram Equalization (MSHE) is proposed where a trade off has been done between over enhancement and low contrast.

In MSHE, at first image mode is calculated which is the most frequent intensity of an image and adjusted with a weighting factor and a bias which gives an accurate separation point to divide the histogram. Afterwords, histogram equalization is applied individually on each part of the histogram. The sub histograms are combined into one to get the desired output image. The overall procedure is shown in Fig. 1.

At the beginning of MSHE, a histogram separation point (X_m) has been identified to separate image perfectly which is calculated by Equation 1.

$$X_m = c + \alpha \times X_{mode} \tag{1}$$

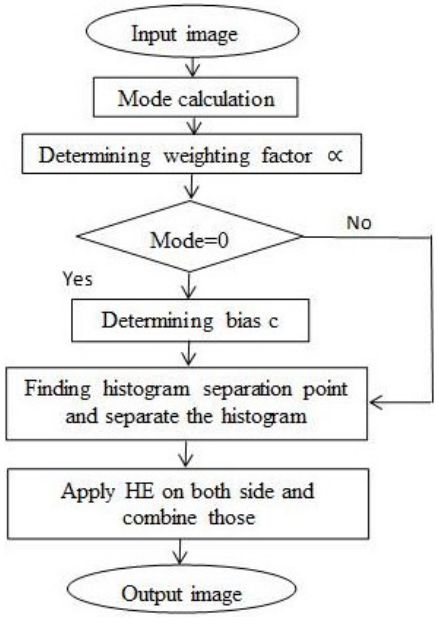

Fig. 1. Flowchart of MSHE

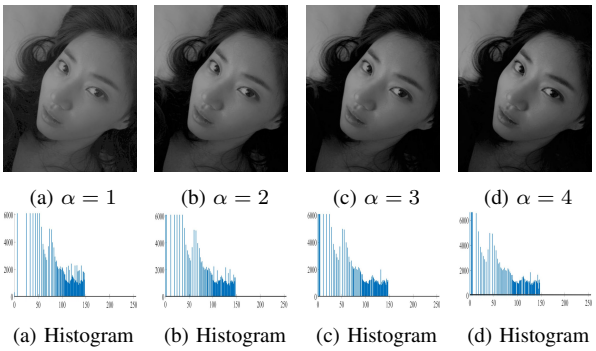

Fig. 2. Impact of using α greater than 1 over 'Girl' image

Here, X_{mode} is the image mode which is adjusted with a weighting factor (α) and a bias (c) where α should be as follows

$$\begin{cases} 0 < \alpha < 1, & X_{mode} = \wp \\ \alpha \geq 1, & X_{mode} < \wp \end{cases} \tag{2}$$

Here, $\wp$ is the highest intensity of an image i.e., 255. When mode is exactly $\wp$, α should be in $[0, 1]$. Again sometimes α needs to be greater than or equal to 1 for getting better contrast when image mode is less than $\wp$. From Fig. 2 and Fig. 3, it is shown that the image contrast is improved with the increase of α where it exhibits that best result when $\alpha = 2$. This weighting factor α is determined using tangent of the difference between two ratios of some statistical parameters calculated by the following equation.

$$\alpha = \mid \tan(\frac{X_{max}}{X_{mode}} - \frac{\sigma}{2}) \mid \tag{3}$$

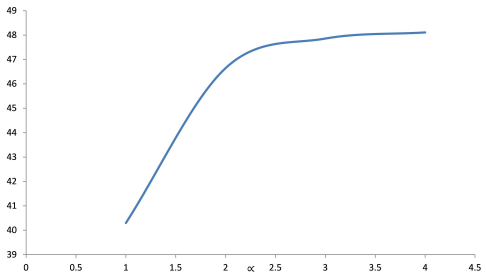

Fig. 3. Root-mean-square contrast of 'Girl' image is increasing with α

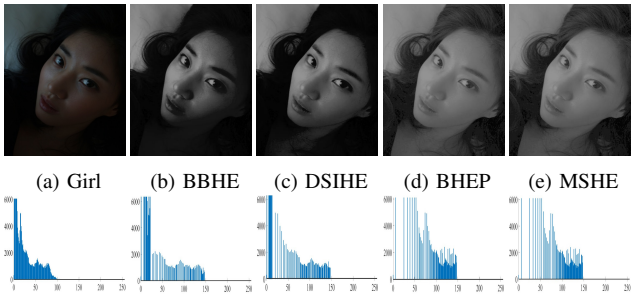

Fig. 4. Rational behind choosing Mode as the separation point

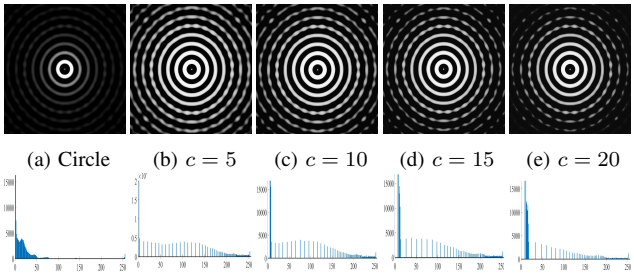

Fig. 5. Rational behind choosing c

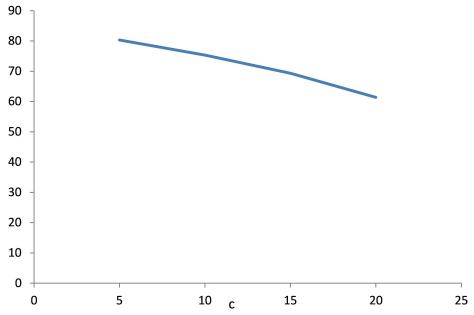

Fig. 6. Root-mean-square contrast of 'Circle' image is decreasing with c

Here, σ, X_{max} are the standard deviation and the maximum intensity respectively. tan function returns the output of input variable that is expressed in degrees. The reason of using tan function is given in Lemma 1 and Lemma 2.

Another factor c is calculated using absolute difference

between standard deviation (σ) and image mean (μ), follows specific condition similar to the Dirac delta (δ) function [25]. c only contains value when most frequent intensity of an image is zero. The impact of c is shown in Fig.5 and Fig.6.

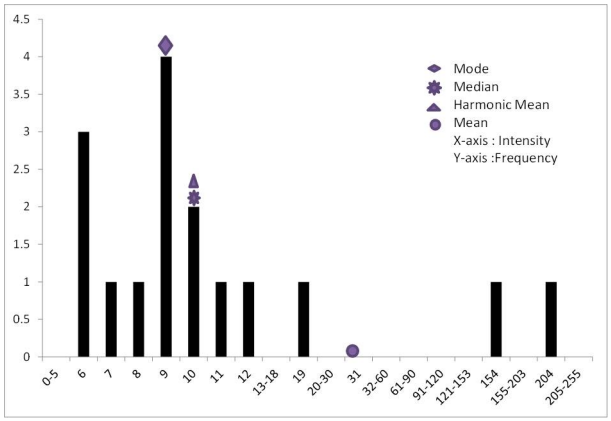

Fig. 7. Impact of choosing image mean, median, harmonic mean and mode

$$c(X_{mode}) = \begin{cases} \mid \sigma - \mu \mid, & X_{mode} = 0 \\ 0, & otherwise \end{cases} \tag{4}$$

Now input image is decomposed into two sub images X_L and X_U based on X_m followed by Equation 5 and 6.

$$X_L = X(i,j) | X(i,j) \leq X_m, \forall X(i,j) \in X \tag{5}$$

$$X_U = X(i,j) | X(i,j) > X_m, \forall X(i,j) \in X \tag{6}$$

Here, X is an input image which is separated using X_m. X_L and X_U are the lower and upper part of the image respectively. The sub image X_L is composed of $\{X_o, X_1, ..., X_m\}$ and the other part X_U is composed of $\{X_{m+1}, X_{m+2}, ..., X_{n-1}\}$. Later, histogram equalization is applied on the two parts individually and finally the output image is achieved by combining the two sub parts.

A. Rational behind choosing tan

Lemma 1 α remains less than 1, if X_{mode} = 255.
proof For $X_{mode} = 255$, the maximum value of α in proposed method will be $\alpha_{max} = \mid \tan(1 - \frac{\sigma}{2}) \mid$. For a choice of $\sigma = 10$, we get $\alpha_{max} = \mid \tan(1 - \frac{10}{2}) \mid = .06992 < 1$

Lemma 2 $\alpha \geq 1$, iff tan is used.
proof When $sine$ or $cosine$ function is used instead of tan, the maximum value of α_{max} can never be greater than one. For a choice, using statistical parameters of 'Girl' image, given in Fig. 2, we get $\alpha_{max} = \mid \sin(\frac{148}{2} - \frac{25}{2}) \mid = \mid \sin(61.5) \mid = .879$, where σ=25, X_{max}=148 and X_{mode}=2. In case of $cosine$ function we get $\alpha_{max} = \mid \cos(61.5) \mid = .477$ where $\alpha_{max} = \mid \tan(61.5) \mid = 1.84$

B. Rational behind choosing Mode

Histogram equalization uses the highest intensity of an image to equalize it, while its extensions like BBHE, DSIHE, BHEP and even MSHE changes its highest intensity by separating into two parts. From Equation 5 and 6, the upper limit X_m is the highest intensity for the separated part X_L and it is used to equalize X_L where X_{n-1} is used for the other part X_U.

$$\begin{bmatrix} 9 & 10 & 12 & 6 \\ 8 & 10 & 9 & 11 \\ 6 & 19 & 204 & 154 \\ 9 & 6 & 7 & 9 \end{bmatrix} \tag{7}$$

The effect of choosing mode instead of mean, median and harmonic mean is described using a 4×4 matrix (Equation 7) which is similar to BHEP [9]. From Fig.7, it is shown that the mean of the matrix is 31 which denotes that 87% pixels (14 out of 16) are on the left side and rest only 13% pixels stays in the right side. As a consequence, the 87% pixels are not enhanced more than intensity 31 in BBHE. But the aim is to divide histogram where pixels are equally distributed on both parts because only this can ensure maximum contrast of an image. Median and harmonic mean are used to divide histogram in DSIHE and BHEP respectively and for this matrix both median and harmonic mean is 10 which signifies 69% pixels (11 out of 16) are in the left side and 31% pixels are in right side. Equal distribution of histogram on both parts is not even ensured in DSIHE and BHEP too. Meanwhile, MSHE proposes mode based contrast enhancement which provides equal distribution of histogram. Here, mode is 9 and α is 1, returns a separation point at 9. This divides histogram into two parts, containing 56% (9 out of 16) and 44% pixels, respectively(according to Fig.7). The impact of selecting mode is also illustrated in Fig. 4.

IV. Experimental result

In this paper, the proposed method is compared with some other existing contrast enhancement techniques namely HE [1], BBHE [2], DSIHE [3], RMSHE [4], RSIHE [5], AGCWD [7], AGC [14]. This comparison is conducted followed by qualitative and quantitative approaches.

A. Qualitative assessment

In this section visual assessment has been performed over a large number of images and the data set has been taken from [1]. Most of the cases, it has been found that MSHE shows better outcome than other techniques.

Fig. 8 (Stonewall) contains a dark image where the main challenge of this image is to read the message written over the wall. It is found that the message can be read in HE but artifacts are also introduced. BBHE does not enhance contrast at all and DSIHE creates accepted enhancement where at least the message can be seen properly. RMSHE and RSIHE produce similar enhancement as in BBHE and DSIHE respectively and this is because for both cases the recursion level have been used one. Although AGC enhances contrast

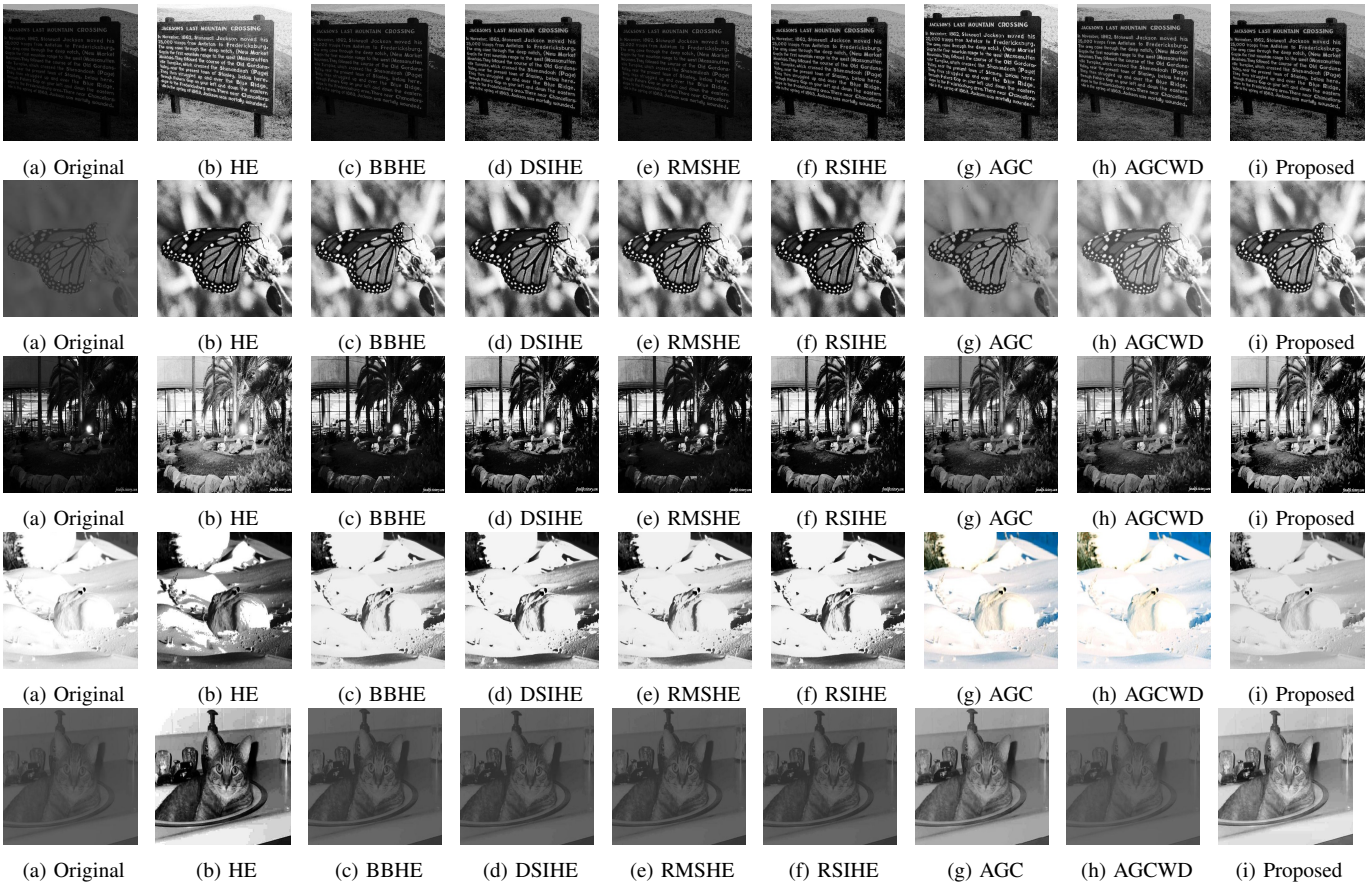

Fig. 8. Enhancement results of different methods (top-down → 'Stonewall', 'Butterfly', 'Fountain', 'Hare', 'Cat')

but it creates a blurry image where the message cannot be read at all whereas AGCWD exhibits the message quite clearly. However, MSHE enhances the image with appropriate contrast where the message is clearly readable without any artifacts.

Another dark image with low contrast is in Fig. 8 (Butterfly) where the main difficulty is to find the image details including the flower. HE, BBHE, DSIHE, RMSHE and RSIHE create over enhancement. Although AGC does not produce over enhancement, it fails to enhance the brightness. AGCWD enhances the contrast well but it produces over brightness problem. Meanwhile, the proposed method shows output with perfect contrast with details. Fig. 8 (Fountain) is also a dark image where brightness enhancement is needed. HE produces desired brightness enhancement. BBHE and RMSHE fail where DSIHE and RSIHE show insignificant impact. AGC and AGCWD show comparative better result but more enhancement is needed for clear visualization, while MSHE is successful for corroborating brightness enhancement.

Fig. 8 (Hare) is a low contrast image where HE shows over enhancement as usual, DSIHE and RSIHE increase contrast more than BBHE and RMSHE respectively. However, all of them need further improvement. In the case of gamma correction, AGC exhibits better result than AGCWD. MSHE enhances without creating over enhancement.

Another dark image with low contrast is in Fig. 8 (Cat) where the major concern is both the cat and its background glasses. HE enhances the image but the background suffers from over enhancement problem. BBHE, DSIHE, RMSHE, RSIHE show no change in outcome. AGC produces accepted enhancement for this image whereas AGCWD almost creates no enhancement. But among all the techniques, MSHE enhances the image properly where both cat and background glasses are equally visible.

B. Quantitative measurement

The quality judgment of an image can vary from person to person. Through quantitative evaluation, it is possible to prove numerically the quality of images i.e., enhanced or not. Here, root-mean-sqaure (rms) contrast and discrete entropy (DE) are used to evaluate the performances of different enhancement techniques along with the proposed method.

1) Root-mean-square (rms) contrast: Measuring *rms* contrast is a well known technique to describe the contrast [17], [18]. Low *rms* refers to low contrast. Table I shows value of *rms* contrast of different methods. From this table, it is shown that HE creates larger *rms* value for most of the images. However, here, over enhancement is severely observed within the images. AGC also produces larger *rms* values. Among the histogram equalization methods, MSHE performs better.

2) Discrete entropy: Entropy refers to uncertainty of an image. An image has more entropy depending on the randomness

TABLE I
Root-mean-sqaure contrast for each algorithm

Image Name	HE	BBHE	DSIHE	AGCWD	AGC	Proposed
Stonewall	74.93	49.48	62.54	60.67	79.05	62.99
Fountain	74.60	68.94	80.26	67.40	63.55	82.05
Butterfly	74.89	72.05	75.44	46.55	35.7	64.92
Hare	74.93	68.10	78.40	45.56	51.0	44.72
Cat	74.70	16.34	16.34	9.86	38.25	48.58

of the variable [16]. Low entropy symbolizes low contrast and higher entropy refers the reverse in image processing. Table II demonstrates the discrete entropy (DE) for each algorithm and it shows that AGC creates larger entropy for all the cases except the 'Cat' image. MSHE holds second larger entropy. Hence, it can be concluded that after AGC, MSHE performs better than other histogram equalizing techniques.

TABLE II
Discrete entropy for each algorithm

Image Name	HE	BBHE	DSIHE	AGCWD	AGC	Proposed
Stonewall	4.92	5.29	5.38	5.40	5.40	5.36
Fountain	5.42	5.91	5.97	7.08	7.24	5.95
Butterfly	4.60	4.78	4.76	4.80	4.80	4.78
Hare	4.92	5.21	5.23	5.09	5.57	5.33
Cat	5.06	4.97	4.97	4.71	5.19	7.20

V. CONCLUSION

As failure of proper partition is a major limitation of histogram equalization based techniques, in this paper we propose a simple and effectual technique for contrast enhancement to abolish this problem. The proposed MSHE determines separation point using mode which splits almost equal area over histogram and produces better enhancement. Its efficacy of producing satisfactory results has been proved over other brightness preserving contrast enhancement techniques by qualitative and quantitative analysis. This motivates to collaborate MSHE with medical image processing, digital photography and other implementations in consumer electronics.

***Abstract*—In the world of modernization, most of the societies are adapting smart technologies for different household, production and professional works. For that, the use of electric power is significantly increasing. In the developing countries, limited energy sources has created an enormous lack of power. Therefore to cope up with the modern world of digitalization and technological advancement, optimizing power consumption has become a very important aspect in this area. So to optimize the usage of power from both national power grid and renewable energy sources to its optimum usage can lead us to a better progression. As most of the modern appliances and systems are being developed nowadays under Internet Of Things, we have used IoT to develop a user-friendly power management and appliance control system.**

Keywords—Internet of Things; power control; power optimization; appliance switching; remote device management; energy distribution.

I. INTRODUCTION

In this era of digitization managing energy is essential in all categories of lifestyle and production whether it's home appliances or industrial machineries. In the developing countries power deficiency is a very common problem. Also the cost of electricity is very high due to scarcity and the scarcity of electric power is increasing rapidly for power wastage and lack of proper usage management. Now a days many countries including the developing countries are using renewable energy sources but that is not sufficient to cover the complete need yet. So power usage optimization is a must for both managing devices and handling the expenses. An intuitive meter powered by a smart controller and an AI modulator that optimizes the electric power usage can solve this matter for most of the cases in an efficient way.

The objective of this paper is to create the guideline for developing a self-regulating power meter that can manage, analyze and optimize the power usage and lets the user assess the power usage situation through a software application. The user will also have control access to the appliances through the software application which is connected to a cloud server that would store all the necessary power usage data sorted by date, time and appliances. The user would have full data and control access to the cloud server, appliances and application system through NFC and RFID. An AI modulator will manage power system optimization using voltage regulator and a complete sensor network system including sensors for temperature, humidity, ambience, lux, noise etc. For example; the controller would automatically turn off air conditioner when temperature is below human comfort level or turn off light at night when need of light is low. The AI modulator would find comfort level, ambience requirement etc. by derived machine learning.

II. RELATED WORKS

Recent researches on the sector of Internet of Things and the power control systems have provided greater advancement in reliable infrastructure for optimizing power in household activities. More research on this aspect have created much efficient smart sensor technologies which allocate us with advanced tools to build up smart home appliances. [1]. As different projects have been done to create a better smart home where the use interactions and securities are given more priority than controlling the power. In the developing countries scarcity of electricity and renewable energy is decreasing modernization in this areas. Also in some places there can be seen renewable energy source but optimization is not up to the marks. In [2] the authors have created cloud based home management system where they incorporated home appliance control, security management through separate medium. In which the expense will be a lot higher and time consuming. The goal of our model is to use renewable energy as much as it can and use limited powergrid to use less electricity. In [3] the author have researched energy management on a city based on canadian condo environment. Where it can be an optimal solution for a particular country but there stands a difference based on availability of the resources.[4] have researched over smart meters for developing countries.

We have proposed a design that can be accessed through smart device of a user to control home appliances and also see optimal usage of power. Where the meter will try to use renewable energy as much as it can and use from power grid when it's necessary. User can access his data using NFC from his smart device and also handle bills through his device. The proposed method can be more cost efficient and can optimize the energy more significantly.

III. Proposed System

The basic outline of our system is devised to orient around a 'smart meter' powered by a customized microcontroller. All the electronic appliances required and installed in any settlement (household, corporation or industrial) are first passed through numbered digital output ports of the microcontroller. Hence any and every device is controllable by the controller. The power output and signal switching are both displayable in the central control monitor of the controller.

The 'smart meter' is connected to the service web server and dedicated cloud server through a dedicated private IP connected PAN (personal area network) by zigbee-IEEE 802.15.4 [5] specification suite, GSM module and basic TCP/IP protocol suite. The GSM module works as the intermediary for the 'smart meter' and the servers (cloud and data) whereas, a combined module suite of zigbee and GSM are used to connect the controller and servers to the controller mobile phone application (android, IOS and windows platform) so that the data access, appliance control and the 'smart meter' all can be managed and controlled by the user.

.

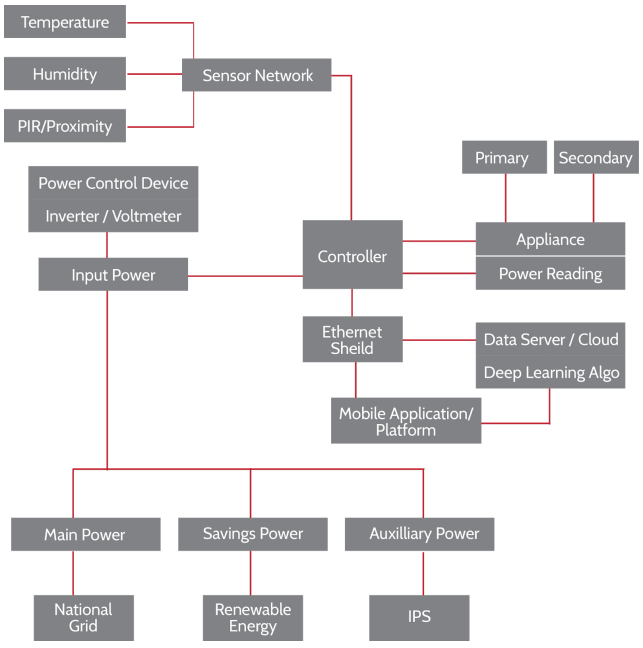

Figure 1: System Workflow Diagram

The main input power for the system and the appliances is provided by a renewable power source like a smart solar power grid or a wind based power turbine system included in the hardware system which is marked as the primary power source while the national power grid line is the secondary power source. There should also be a backup substation or an IPS for emergency power supply.

All the power usage data for every appliance and the switching control information is to be stored in the cloud server, and maintained and analyzed by the AI modulator. The modulator analyzes the usage data per time per day per season per device and optimizes the further power management and switching automation for future usage. The AI modulator generates automated power usage reports and gives warning for excess power usage on heavy load.

IV. Methodology

The overall method of our system is based on a customized microcontroller and interconnection between cloud server. There are several important aspects in our proposed system. As our propose system smart power meter optimizes power usage, it tries to use as much renewable energy it can before using power grid. For that a inverter is used. An AI modulator controls the home appliance based on the results from different sensors (e.g. temperature sensor, humidity sensor). For a user to access it requires a security measure also. The system architecture can be seen for our proposed system below.

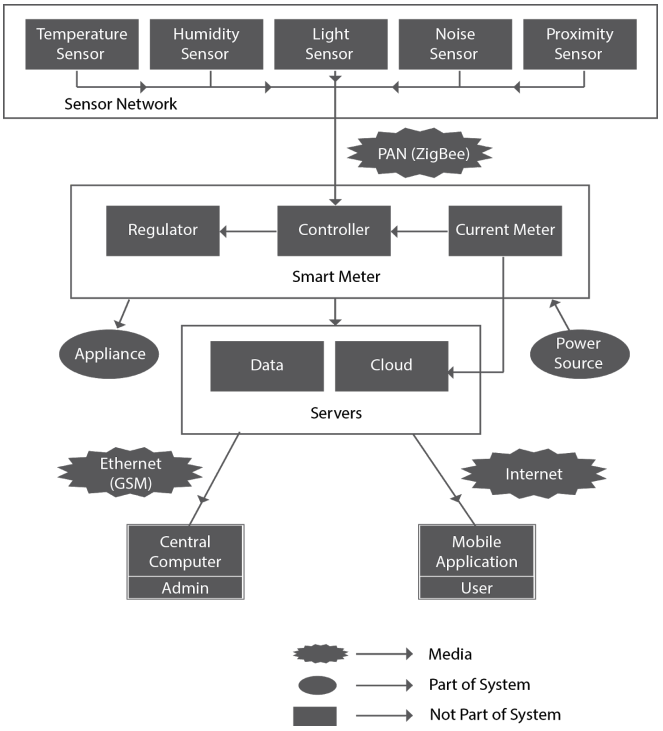

Figure 2: System Architecture

Our proposed approach can be divided in to three significant parts:

- Sensor Networks
- Smart Meter
- Cloud Server & Security

A. Sensor Network

Our proposed system provides a smart solution for controlling the home appliances based on an AI modulator. Which works depending on sensor outputs. Sensor networks includes a combination of temperature sensors LM35 [6] and humidity sensor [7] connected through a Zigbee to control the home appliance if the temperature changes from a threshold value. It also includes light sensor for controlling the lights. Passive Infrared sensor (HC-SR501) [8] and sound sensor [9] are also included for accurate monitoring of the home appliance control. If the one or two sensor value was more than a threshold value but unexpectedly the home appliance failed to shut off the PIR sensor will ensure its situation to shut it off to the smart meter.

B. Smart Meter

The dominant part of our model is the smart meter. It is based on a customized microcontroller which is connected with the power sources. The meter is powered with three types of connection where one is renewable energy, power grid and finally auxiliary power. The first objective of the smart meter is to use renewable energy as much it can then using the national power grid as needed. If a load shedding or a mishap occurs the third auxiliary unit (IPS) takes over the line. Smart meter counts the usage of power grid and inform the users how much units of electricity it have used and calculate the cost. It will also predict and advise the user about how much units of electricity he should use for most optimal results. Other than the AI modulator the user can manually control the home appliance through his smart devices. The power distribution of the smart meter relies on a inverter which connects to the necessary power source as described. An user is needed to authenticate themselves before getting the data from the smart meter. In our proposed model we have used nfc which is available in every phone. After authenticating through the nfc the user can control, see the usage and also pay the bills through local mobile transaction system.

A flow chart for the smart meter can be seen on figure-3 where the power distribution process is described briefly. All the data of energy consumption and optimization are then send in to the server where it all gets stored. The AI modulator interacts with the server data to take more proper decision optimizing the energy. Which provides user with more energy efficiency and cost effectiveness.

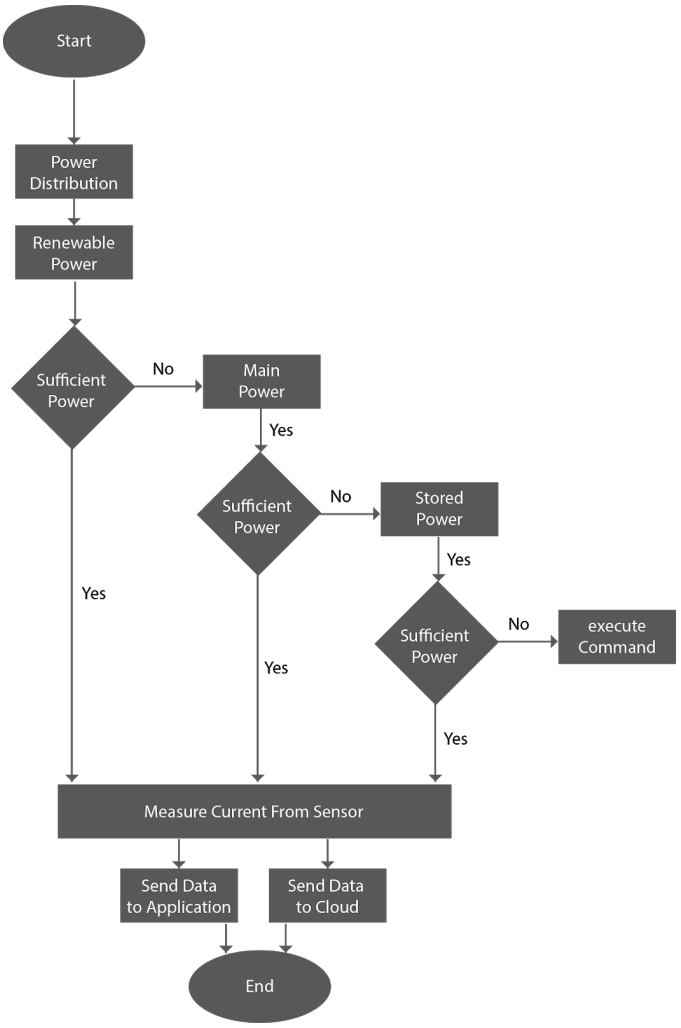

Figure 3: Flow chart for smart meter

C. Cloud Server & Security

Like any other management and optimization system or automation; the proposed power management system also contains a data management server system. But to improve the efficiency of the IoT themed system the model is planned to have cloud server instead of a central data center. As the power usage data is quite sensitive the cloud server (preferably AWS) is designed including CCSK test version 3 cloud security system by implementing 6 layer 'onion server' technology and a dedicated private IP based PAN.Only the meter system and AI modulator can access the server to analyze usage data for further optimization.

Application for proposed System

We have created user friendly application that acts as the bridge for communicating with the smart meter and user acce-

-ssibility. The application provides user with the options to collect the power usage and consumption reports from the smart meter through the cloud server. The user can also control all the home appliances connected with the smart meter. Application also provides billing facilities through local payment gateway. The application can be accessed by the nfc from the user devices. An interface prototype of our application can be seen below.

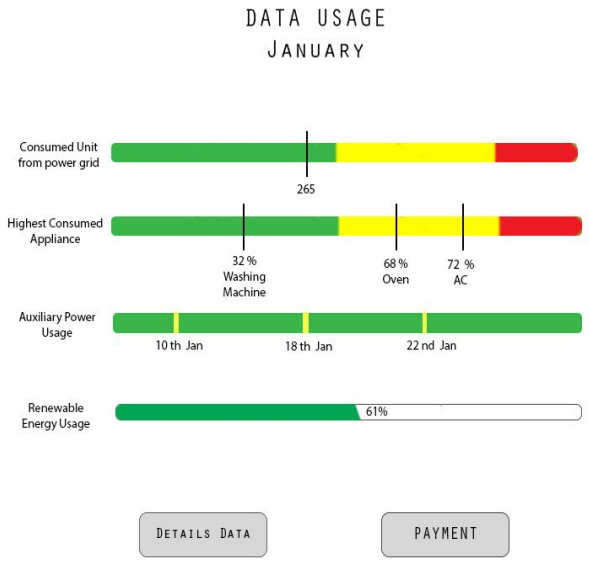

Figure 4: Application interface prototype for smart meter

Emergency Cut off

The proposed system also includes an emergency shut down system where if the microcontroller assigned to smart meter detects any kind of massive temperature variation while distributing power and changing power source through inverter the system cuts off the power until the temperature is back to normal.

V. Collation and Analysis

The proposed prototype is evinced to have a capability of around 18% reduction in power consumption in a closed environment; be it a residential or commercial settlement.The reduction includes switching off unused appliances, load transfer for heavy duty machineries, power switching between grid line and secondary power source for usage optimization and voltage regulation of common appliances.Also the system can ensure a better settlement security through the three layer monitoring sensor network. User can also compare power usage data for different electronic devices based on data & time. This power usage data in cloud database can also train the application AI to future enhance its decision making capabilities; i.e. whether to on or off AC during winter or whether to on or off lights during night-time on its own.

Most of the existing systems like EHS , Insteon, KNX, Z-Wave, X10, UPB, Lon Works , Zigbee etc. are based on short wave and local area connection network for IOT based appliance control. These standards connect the central controller to the required devices in a wireless PAN. Except Zigbee, all other protocols are prone to external hacking and network attacks, as they utilize the open bandwidth of the wireless frequency band.

All the existing systems only serve the purpose of appliance control and remote device switching with a minimal monitoring option. Our designed system model utilizes a dedicated cloud server for data storage and power usage data analytics for future application references. The integrated AI in the cross-platform mobile application would generate alerts and warnings based on unnecessary switched on devices and power over-usage. Thus unlike most existing systems this model can effectively control and minimize over usage and wastage of power. Also the user retains all authorization and full control over both the system and the application.

VI. Conclusion & Future works

Our plan for the smart meter is to incorporate it to the national grid line and all end user power consumer settlements. That way the whole power line for an area can be effectively organized and optimized. Also the power wastage can be reduced which is a very significant aspect in the developing countries or countries with scarcity of power resources. We have tried to incorporate most of the aspects that contributes maintaining a more optimized use of power. More use of renewable energy not only helps the environment but also lessens the expense of a user. Smart technologies combining with artificial intelligence can guide the user towards substantial energy efficiency.

In the near future our primary plan is to assimilate our own deep learning algorithm in the AI modulator; so that it can analyze and synthesize more data with faster speed. Also by deep learning the modulator will be able to optimize the power automation system further. We are already working on the deepmind api an open source platform by google inc. In near future we hope that about 70% of our daily power needs will be met by renewable energy, which can be solar power , wind power or any other renewable energy source. We are also trying to incorporate smart solar power grid and also enhancing the custom microcontrollers to be more precise so that energy efficiency becomes easier which can lead to a better environment and better living.

***Abstract*—Internet-of-Things (IoT) has introduced new avenues of application development towards the Smart City vision. Urbanization is a common trend of current society and its rapid growth demands smarter solutions for waste management in the cities. A probable solution of this problem is the adoption of IoT based waste management systems. In this case, we have to build smart bins that will be connected with the cloud setup of the city authority and will provide constant updates of the waste status of the bins. A critical issue in this case is to provide power to this smart bin establishments. This problem can further be handled by incorporating reusable energy sources such as solar panels with the smart bin setups. In this paper, we design and develop an IoT and cloud based framework for waste management. We have designed and developed smart bins that are intermittently connected to the cloud data storage to share their waste status. City authority is given required web interfaces to manage smart bin installations. Garbage collectors are given mobile applications to help planning garbage collection routes dynamically.**

***Index Terms*—Waste Management, Green IoT, Smart Bin, Arduino Microcontroller, Reusable energy**

I. Introduction

New technologies are sweeping the market every day with one specific goal, improving our daily living experience. IoT is an enabling technology to solve issues related to rapid urbanization. One key problem of urbanization trend is waste management of the cities. Bangladesh is also facing the same problem. Adopting IoT technologies for waste management can provide some solutions to this problem.

Bangladesh is a country with small land but large population. The number of city dwellers in Bangladesh is constantly increasing in regards to the management capacity of the city authority or the city infrastructure [13]. As a result, there is more waste, which requires more man power to collect for disposal. Due to the lack of man power and proper planning waste management procedure is not scalable. This has caused tremendous distress for the overall health of the citizens as well as caused severe damage to the environment.

Implementation of Smart City through the adoption of IoT offers a viable option to overcome this problem. In the event of CES-2018 several technology leaders have demonstrated the practical use of the Smart City Concept [3]. If we can connect all types of citizen services in a city with the internet, then citizens and the administration can communicate better, which is important to improve the quality of city living. Government of Bangladesh also has the vision to improve the digital services of the country. The main issue of adopting new technologies in Bangladesh is the requirement of power. Due to lack of adequate power generation, utilization of renewable energy for IoT technologies is a viable option for Bangladesh. This however is termed as Green Internet-of-Things i.e. Green IoT.

Green IoT focuses on energy efficiency from all perspective of IoT deployment [2]. It is believed that billions of IoT devices by 2025 will consume enormous amount of power that will contribute tremendously to greenhouse effect [5]. Adoption of green power source will ensure that IoT deployment is environment friendly. With this objective, we have designed and developed IoT based waste management system that can scale as well as utilize green energy to power the service. History data from the system will be used to identify the areas that require larger bins as well as increased number of bins. City authority can use this data to rearrange bins locations as well as improve necessary garbage collection attempts to ensure cost efficient health city living.

Rest of the paper is organized as Section II describes state of the art works from smart dustbin, smart waste management and IoT based waste management perspectives. In Section III, we describe the architecture of our proposed Green IoT based waste management system for Bangladesh. Section IV later presents detailed implementation approach of our developed prototype, which leads to Section V that concludes the paper.

II. Related works

Smart City applications are the latest trend in IoT research. Smart waste management in the cities is a significant application of this genre. There are some research works related to smart waste management that are utilizing IoT technologies. Most of the smart waste management models tackle the problem related to any specific country. Following sections describe some state of the art solutions of smart waste management.

In [7] authors describe about smart dustbin for Smart Cities. In this system there are integrated GPS and Wi-Fi enabled Smart Bins. The system has three layers – Dustbin Layer, Server Layer and Client layer. Dustbin Layer consists of some hardware including Arduino UNO R3, Sonar sensors and Wi-Fi module. Server Layer is basically data layer where Wi-Fi module updates dustbin position and current state. Client Layer receives data from the server to observe the status of the bins.

In this paper [8], authors demonstrate how IoT can be enabled with data access networks, geographic information system and electronic engineering works to improve traditional waste management system. In their solution, waste is collected by gathering intelligence about trashcans, where the prototype is embedded with sensors that can collect and transmit trash volume data over the Internet. Spatio-temporal context of the data is considered in this data collection model that further uses graph theory optimization procedure to handle waste efficiently.

Raina et al. [10] presents a concept about smart garbage collector that uses microcontroller to watch the status of the garbage bin and report the status in an HTML page. They use different types of sensors to collect the information about the garbage, which is shared using wireless systems. HTML page is also accessible through smartphones. Here they have created a server in Wi-Fi module to send data in HTML page, later they access data from any Internet-enabled devices.

In this paper, we propose an IoT based green waste management system. The proposed system is divided in three parts: Bin layer, Data layer and User layer. In the bin layer we have smart bins that are loaded with different sensors to collect garbage level information from a bin, communicates the data with the data layer. Two types of users waste management monitor or garbage collector can access this data for garbage collection route finding or for statistical analysis.

III. Proposed System Architecture

In this section, we provide details of the proposed IoT based green waste management system. Fig. 1 shows the proposed architecture of our system. We have divided the proposed system into three parts: Bin layer, Data layer and User layer. Bin layer consists of Smart Bin that is designed to collect garbage status data. The data layer contains a centralized server that stores garbage related data collected from different smart bins installed in different parts of the city. For the user layer we have two types of users: garbage collector and system monitor. Both of these users can access the garbage status data of various smart bins as required.

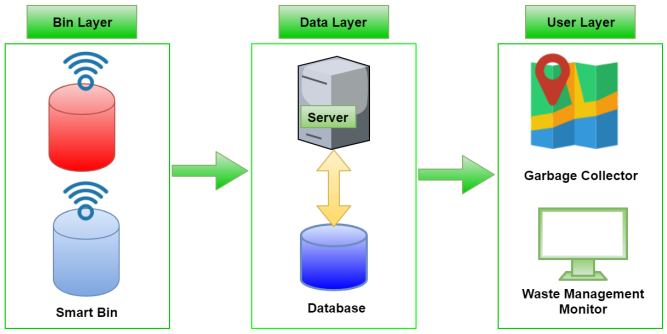

Fig. 1. Architecture of proposed IoT based green waste management system

Both the bin layer and the user layer are connected to the data layer for their operation. Our system is a one-way communication system which only collects data about the physical world. Bin layer directly sends its data to the data layer. Data layer stores information in the cloud and the user can collect information from the cloud whenever required. Garbage collector and system monitor individually collect information from data layer. The proposed smart bin depends on solar power for energy source. As a result they can be installed in any new places as long as solar energy is available. GPS location helps to locate the bins automatically from the cloud server. Following sections describe the system in details.

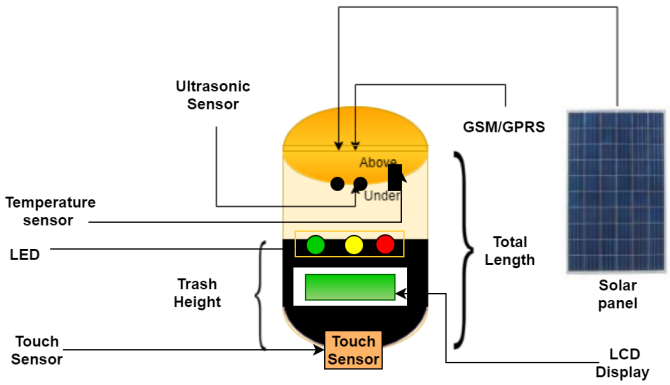

Fig. 2. System design of proposed smart bin

A. Bin layer

Bin layer of the proposed system consists of all the smart bins deployed in a target area. Every smart bin (Fig. 2) is built of a list of sensors and a microcontroller (e.g. Arduino AVR) that hosts the software to operate these sensors. In our system we have used Ultrasonic sensor, Temperature sensor and Touch sensor to measure different aspect about the smart bin. An ultrasonic sensor is used for measuring the height of the bin's waste level. The number of ultrasonic sensors will vary based on garbage bin's size. For example, a small bin can work with one sensor whereas a larger bin will require more sensors placed in different areas of the bin. Generally, ultrasonic sensor uses ultrasound wave that reflects, when gets to any barrier. We use this sensor to measure the level of the garbage in a bin from the following equation:

$$Garbage\ level(meter) = (Velocity\ of sound)/Time\ delay \quad (1)$$

We have used temperature sensor to sense internal temperature of the bin. Since, different waste has a different temperature, we can assume the types of waste. As we mentioned earlier every smart bin can be placed in remote places, we use a GPS module to know the location of our bin. A wireless module (e.g. GSM/GPRS) is used to transfer garbage observation data to the central server. Our proposed system has indicator LEDs to display the level of garbage. We have added a Touch sensor to open bin's lid automatically. And finally, a solar panel is added to the smart bin along with a

battery to store the energy. Capacity of the solar panel may vary considering the number of ultrasonic sensors based on the size of the bin. Every bin is assigned a unique ID. Whenever a new bin is added to the centralized system it gets initialized.

B. Data Layer

Data layer stores continuous garbage update in the cloud database. Every bin from the bin layer communicates with the central data layer and delivers the garbage status intermittently. Fig. 3 shows the ER diagram of the data layer. Every smart bin uses wireless module to communicate with the data layer. From the database, user can find the history information about a particular smart bin and its current and previous installations. Every bin has a mode: active and inactive. If an existing bin needs to be relocated then the mode changes to inactive and then the central control system informs the administrator of the system about this action. Data layer manages history and current data for both active and inactive smart bins.

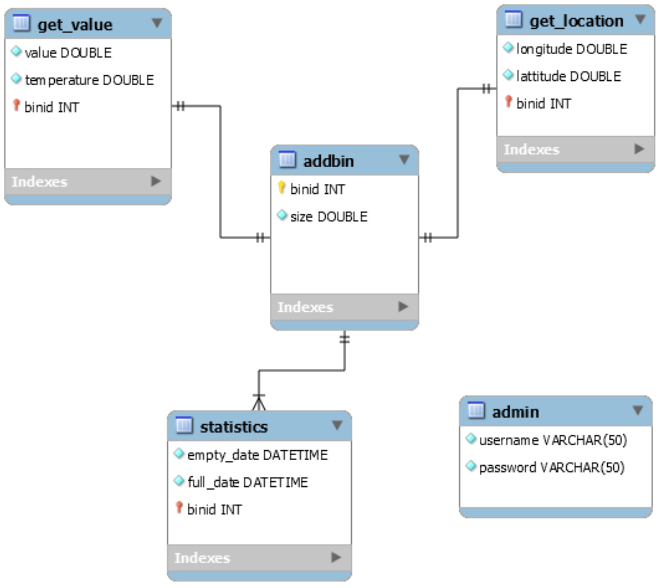

Fig. 3. Entity relationship diagram of the data layer

C. User layer

In our proposed system users are of two types: waste management system monitor and garbage collector. Following sections provide details about these user types.

- **Waste management system monitor:** This user is the administrator of the system. For each city authority there can be a list of monitors who will continuously monitor the current status of the overall system. An administrator can add, update and delete a smart bin from the central system. Also, statistical data is only available for the system monitor. Smart bins can be positioned as tags on online maps such as Google Map. System monitor can operate various types of data analytics on the history data, which will be provided to the city authority to make important decisions about waste management policy update.
- **Garbage collector:** In our proposed system, garbage collector is an user who is responsible to find the shortest route of available full garbage bins and pickup the garbage. This part of the system improvises the current model, where a garbage collection track travels to every bin whether it is full or not. In our model, only full/almost full smart bins are considered as candidates for pickup which reduces the energy cost and as well as keep the environment of the bins healthy.

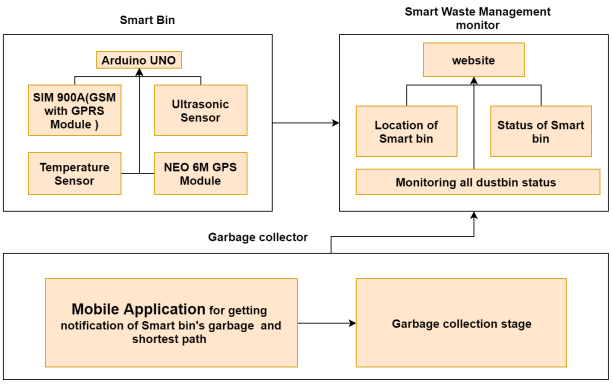

Fig. 4. Prototype application development procedure

IV. Prototype Implementation

In this section we describe the prototype implementation procedure of the proposed IoT based green waste management system. Fig. 4 details the implementation procedure of the proposed system. In order to prove the efficacy of the proposed model, we have developed a smart bin, a cloud based data server that provides user interface to both garbage collector and waste management system monitor. For the usage of garbage collector we also have developed an Android based mobile application. Location of the bins are visible in Google map that is available in the web application.

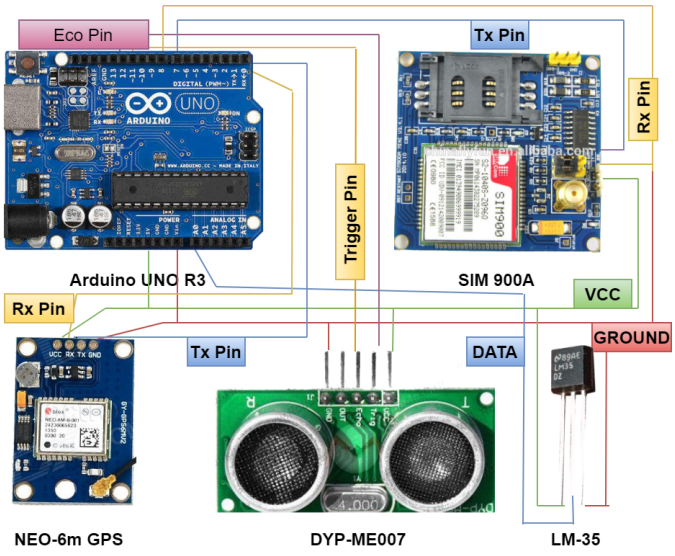

Fig. 5. Smart bin circuit diagram

A. Smart bin development

For smart bin development we have used the circuit diagram mentioned in Fig. 5. Our central processing unit is an Arduino UNO R3 board. A Ublox NEO-6m GPS module is connected with RX and TX pin of the Arduino UNO R3 board. On the other hand, SIM 900A GSM/GPRS Module is connected with a custom made RX, TX pin of the Arduino board. Ultrasonic sensor's trigger and echo pin are also connected with Arduino. The ultrasonic trigger pin is used for sending ultrasound wave and echo pin for receiving the signal. Temperature sensor's data pin is connected to the Arduino's analog pin. Temperature sensor works on voltage level, so we have connected it with an analog pin. All devices work in 5V DC power. A short description of each of this module is provided in the following sections.

- **Arduino Uno R3:** Arduino UNO R3 is an Arduino AVR based physical programmable circuit board, which is largely used for prototype hardware development. Arduino UNO R3 is based on ATmega328P microcontroller that provides 14 digital pins and 6 analog pins for hardware integration. Arduino board supports only DC current. As a result DC adapter is required, where recommended voltage is 9-12V DC, and minimum current supply is 1 Amp [4].

- **SIM 900A GSM/GPRS Module :** SIM modules are widely used for GSM and GPRS services. In Bangladesh SIM900A is easily available as it cheaper and more reliable. It works on two data frequency, 900MHz and 1800MHz. This device supports AT command and requires 5V DC and minimum 1Amp current supply. To prevent this module from restart more than 1 Amp current supply is recommended [9].

- **DYP-ME007 V2 Ultrasonic Sensor:** DYP-ME007 V2 ultrasonic ranging module is a high performance cost-effective non-contact distance measurement module with temperature compensation. It has two integrated receiver and sender. One is for sending ultrasound wave and the other for receiving. Measurement range for this device is 3 400cm, resolution 1cm and measures the target object without direct contact. Its operating voltage is DC 5V and operating current is only 10mA and response time is 100ms [1].

- **Ublox NEO-6m GPS Module:** The Ublox NEO-6M GPS engine has high precision binary output. It has also high sensitivity for indoor applications. The GPS module has a battery for power backup and EEP ROM for storing configuration settings. The antenna is connected to the module through a ufl cable which allows mounting the GPS in such a condition that the antenna can always have the open sky for best performance [12].

- **LM35 Temperature sensor:** The LM35 series are precision integrated-circuit temperature sensor that outputs a voltage which is linearly proportional to the Celsius (Centigrade) temperature. The LM35 sensor works on the analog pin. It receives voltage and returns voltage in bit pulse. Then this bit can be converted in Celsius or any units [6].

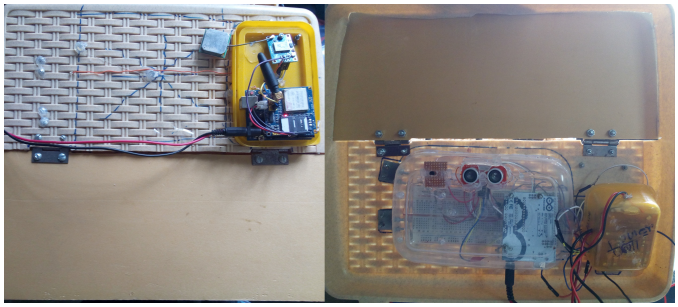

Fig. 6. Smart dustbin top and sensor view

Fig. 7. Smart dustbin side view

In our implementation of power supply we have used 12V, 9A dry cell battery and 10W solar panel. A 10W panel is enough to produce power for the system. When sunlight is available the system takes power directly from the solar panel. During insufficient sunlight, the system takes power from the battery. We have used dry-cell because it gives more efficiency than a lead-acid battery. In our test, battery back-up of our system was 19 hours, without solar light. In Bangladesh, we have sunlight approximately 11 hours in a day around the year [11]. To be fully charged up, the battery needs approximately 10 hours of sunlight. During the first boot, the system may take 15 to 30 seconds, depending on GPS signal. For having a better signal, we have placed it in an open field. Sometimes the ultrasonic sensor may provide some error data, generally 10 to 20 millimeters. For bigger size bin, it does not make any effect. In the test case, we have used a square bucket height

of 42 centimeters. We have also provided a lid on top of the bin. Fig. 7 shows the complete view of our smart bin.

B. Web application of waste management system

Our website provides full user interaction with the system. Anyone can see our website. Our website has two feature, one admin service and another general user. General user can see all Smart bin location in Google map shown in Fig 9. They can also see, individual Smart bin's status, temperature, and location. Anyone can search smart bin with an individual BIN ID. A user can also see individual smart bins last one month fill up and empty time and date. From this administrator can also monitor garbage collector efficiency. Administrator has features to Add Smart Bin, Delete or Edit if necessary. From smart bin fillup and empty statistics, admin can decide whether bin size needs to be changed. We used reverse geocoding to get location dynamically from longitude and latitude. So, if any Smart bin's longitude and latitude is changed, it automatically updates its location. We used Ajax to load page dynamically. Fig. 8 and Fig. 9 show our web application's home and map views. On the other hand Fig. 10 shows smart bin's live status.

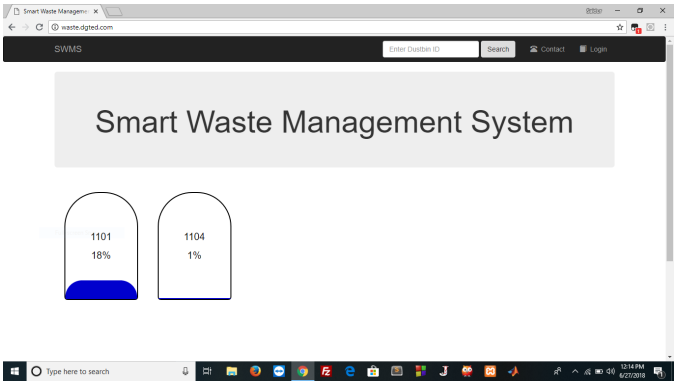

Fig. 8. Web application view

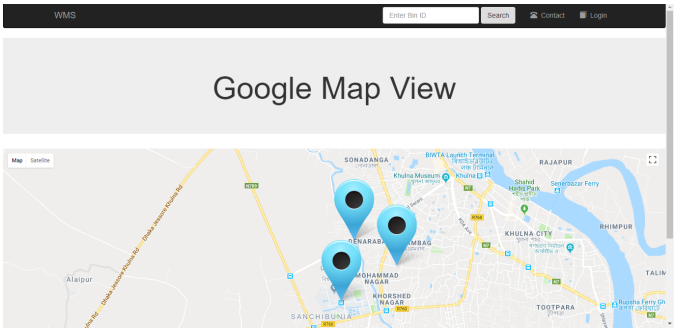

Fig. 9. Map view of smart bins

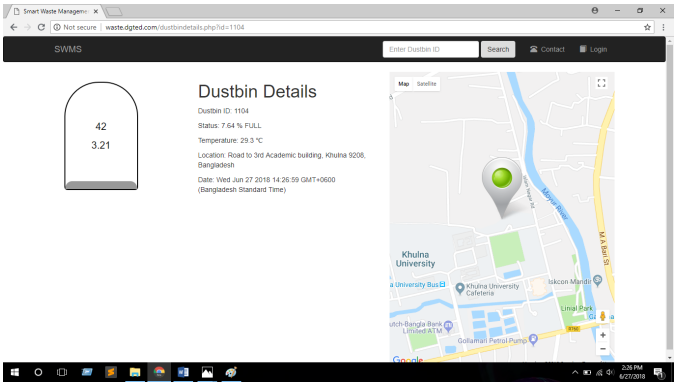

Fig. 10. Smart bin home page

C. Smartphone application

We have also developed android based smartphone application keeping garbage collector user role in mind. In our Android application we find a route to pickup all the full smart bins so that fuel efficiency is improved for the garbage truck. Generally Android app shows every smart bin's location with a marker in Google map. Marker color changes depending on Smart bin's waste status. It only generates the shortest path to the filled bins. Fig. 11 shows the pickup route of our deployed bins.

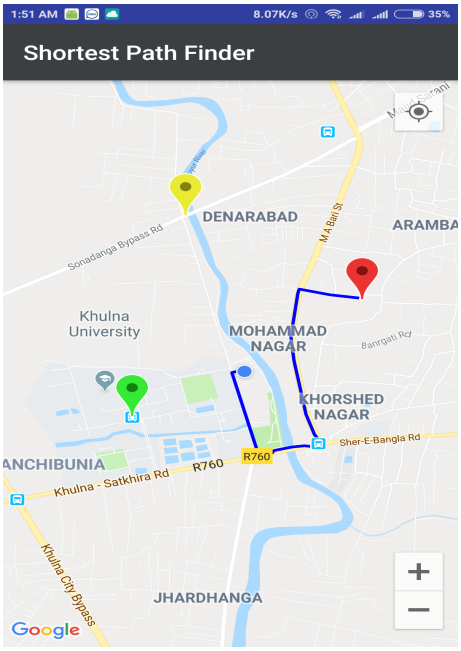

Fig. 11. Android based application for garbage collector

D. Limitations

Hardware implementation is critical challenge for the proposed system. The main issue is the scarcity of different required components and their quality of service. Specially in Bangladesh it is difficult to get many kinds of hardware components in due time. Some hardware components give faulty reading. For example, DYP-ME007 Ultrasonic sensor is

not capable of giving actual height. Sometimes it returns 10-20 cm error. SIM 900A module supports only two bandwidths. Also, Neo-6m GPS gives some error. Integration of the smart bin with the cloud based web application is also challenging due to time delay of the mobile operator's internet service.

V. Conclusion

Bangladesh is a developing country facing critical growth for city life expansion. More people are moving towards city based life and it is becoming difficult to plan waste management for the city authorities. With the application of IoT in the field of smart city management, we can now explore the avenues of smart waste management using the power of technology. In this paper, we propose an IoT based green waste management model, where smart bins equipped with sensors can continuously update the city central server about their garbage status. In our proposed model, smart bins use solar power for the power generation, which makes it more viable for Bangladesh based deployment. As city authority possesses current data about the overall garbage bin status of the city at any time, it can make efficient plan. We hope our efforts will help to eradicate waste management problems of different Bangladeshi cities.

Real-time Water Vehicle Monitoring and Tracking System for Bangladesh

Mohammad Salah Uddin and Md. Naim Khan
Department of Computer Science and Engineering
East West University, Bangladesh
{akash.bangla,naim1248}@gmail.com

***Abstract*—This paper presents a monitoring/tracking system for water passenger vehicle such as vessels or ferries. Bangladesh is a land of rivers. Each and every year peoples die due to accidents in water vehicles. The rescue teams are unable to reach there on time due to the communication barriers which causes huge damages in life. On the other hand, some captains of ferries/vessels do not maintain the weather notifications as well as overload the vessels before leaving the terminal, which are the main reasons for accident listed by BIWTA. In this regard, we have proposed real time monitoring/tracking system for water vehicle. The system (continuously) monitors the status(such as geo-location, load information, the orientation etc.) of the vehicles and sends reports to the ground/control station. As a result, the ground station will always be aware of vehicle status. The details design and implementation of proposed system are also discussed in this paper. The proposed system increases the safety by reducing the number/chances of accidents.**

***Index Terms*—Emergency Device, Water transportation, Monitoring and tracking, GPS tracker, Embedded Systems, internet of things etc.**

I. Introduction

BANGLADESH is a land of rivers that crisscrossed throughout the mostly flat territories of the country. Padma, Meghna and Jomuna are the three largest rivers of Bangladesh. It has about 24,000 km. of rivers, streams and canals that together cover about 7% of the country's surface. Water transportation is comparatively cheaper than road and air. So, Inland Water Transport (IWT) is a prime mode for the transportation of people as well as goods. Therefore, several thousands number of ferries/vessels, country boats are traditional transport which have been playing a key role in inland and coastal water for hundreds of years as a major form of transportation of this country. Though it supports in a wide range in transportation for general but it is claimed that it is notoriously dangerous due to the existence of a big number of accidental reports in this sector. Some accidental data are shown in Table-I.

According to Dhaka Metropolitan Police(DMP) and BIWTA(Bangladesh Inland Water Transport Authority), The main reason for accidents are:

- Unauthorized overloading with passengers or cargo;
- lack of skills and awareness of masters;
- Rough Weather;
- Sketchy design vessels (without following proper specifications);

Indeed, this is the suitable time to come forward to modernize and develop the inland water transport sector of Bangladesh. To do so we are presenting a system that will monitor the vessels/ferry or country boat to track the location continuously and notify to the authority for taking actions immediately. Thus, it may help to reduce the unwanted accidents and sufferings of the people in water transportation sector and save valuable lives.

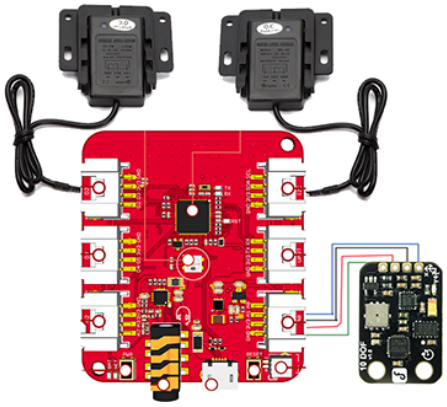

Fig. 1. The hardware design of the proposed system. The device is installed on ferries/vessels.

This paper is organized as bellow: The state of the art is presented in Section II. Section III deals with hardware requirements. The proposed system is described in Section

IV and result is presented in Section V.Finally, conclusion is given in Section VI.

II. State of the Art

The popularity of Internet of things(brief description is provided in section-VI) are increasing day by day in the area of remote monitoring system. The remote monitoring systems include, vehicle or assets monitoring, kids/pets monitoring, fleet management, parking management, water and oil leakage, energy grid monitoring etc.

Real time smart anti-theft vehicle monitoring system based on internet of things is presented in [9].The system allows users/vehicle owners to monitor their vehicle movements information (location log data). Google maps based mobile application has been used for visualizing the vehicle's movement. Additionally, NFC (near field communication) based small tag is used for proving extra layer of security.

Robi-tracker [10] and Finder [11] are other type of vehicle tracking system commercially available in Bangladesh. Those system are able to perform real-time location tracking of the vehicles. Some additional features such as geo-fencing, remote engine Off/On, speed violation etc. are also added with them.

Uber and pathao are most popular ride sharing system in Bangladesh. Driver and rider track their vehicle's movement/location in real-time by using a mobile application. A snapshot of mobile application is available in Fig. 2.

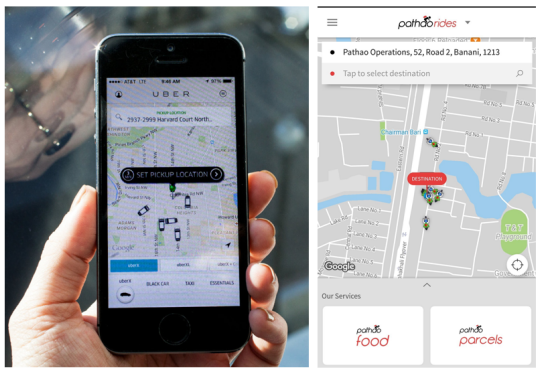

Fig. 2. Screen-shot of Uber(left) and Pathao(right) application.

A fixed route, simple bus tracking system has been proposed by Lau in [12]. The status of the bus after specified time interval has been provided using LED panel and a Smartphone application. The bus tracking systems are beneficial to college students who attend colleges with large campuses. They (students) can spend more time studying, sleeping, or relaxing rather than waiting for a delayed bus. Nowadays, almost all the European countries are using similar type of tracking system for public transportation. Some other embedded system based vehicle tracking system are presented in [13]–[15] Nowadays, traditional satellite based fleet management system has been using by malitries and airlines companies. Sky Connect(TM)Tracking System [16] one of the powerful tracking systems which has been used by these companies. Some developed countries are using intelligent transportation system for monitoring inland vehicles.

The above discussed system are only designed for ground vehicles. Those type of system are not perfectly suitable of water vehicle because of missing some additional information such as vehicle orientation, vehicle weight after loading,sinking level etc., which is important for water vehicle monitoring system. With this regard, this proposed system will played an important role for real-time communication for water vehicle.

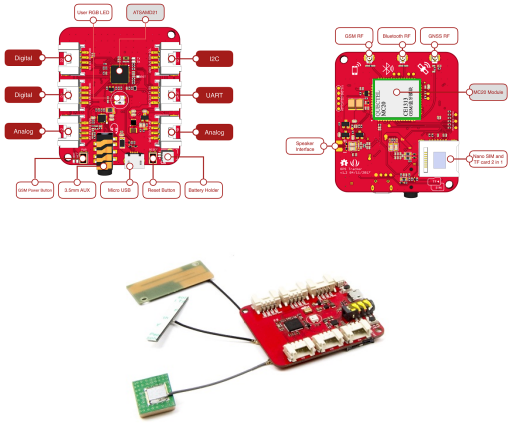

Fig. 3. Wio Tracker IoT Development Board. Source: SeeedStudio [17].

III. Hardware Requirements

A. Wio Tracker Development Board

Wio Tracker (Fig. 3) is an Arduino compatible IoT development board. The board was developed by SeeedStudio [17], a Chinese open source hardware manufacturing company. They have launched the Wio Tracker early in June 2017. The development board consists of 32-bit ARM Cortex-M0+ microcontroller. GSM & GPRS as well as GPS (Global Positioning System) & BeiDou [18], are also integrated with this board. SeeedStudio provides a full documentation of the board which is available in [19]. The board provides an all-in-one solution for tracking based IoT project.

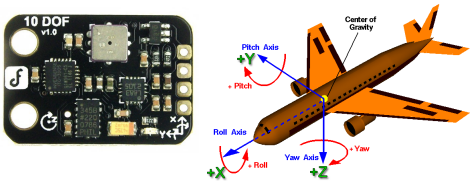

Fig. 4. The IMU sensor and the orientation measurement method.

B. Inertial Measurement Unit [20]

Inertial measurement unit (IMU) in Fig. 4 is used for determining the orientation of an object. IMU sensor are widely used in Air craft to determine the orientation. Its

also used in Human-computer interaction(HCI), Navigation and in the field of robotics. In this work, we used the IMU sensor for calculating the orientation of the water vehicle. The orientation information is useful for determining the stability of the vehicle. The stability information help us to decide whether the vehicle is in danger or not;which may reduce the risk of unwanted accident.

Fig. 5. The Water level sensor and its application.

C. Water level Sensors [21], [22]

Water level sensors are used for determining the presence of water or measuring the amount of water. Two types of water level sensors are available contactless and contactable. Contactable uses some copper wire which placed parallel to each other and contactless sensor uses hall magnetic effect for determining the presence of water. The details about contactless water sensor(in Fig. 5) are discussed in [21].

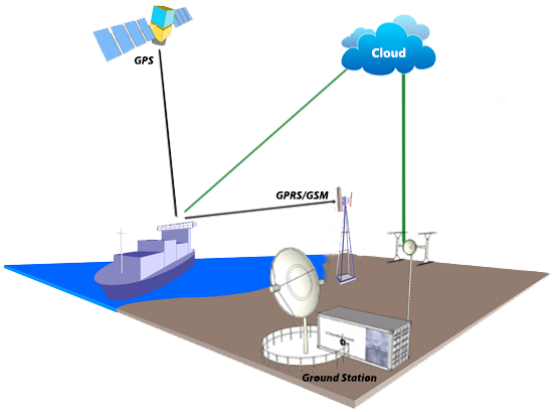

Fig. 6. Architectural view of our system. The Device(in-vehicle) is mounted on the vessels/ferries. It collects data(location, orientation and load information from sensors) and transmits them to the cloud by using GSM/GPRS or 3G/4G(if available) network. The ground station visualize those data from cloud.

IV. System Architecture

The architecture of our system is shown in Fig. 6 and the hardware design in Fig. 1. We choose Wio tracker open source development board as a main controller unit for this system. Multiple water level sensors are used here for determining the water level accurately. We calculate the load of the vessel/ferry by using displacement tonnage (details in [23]). Those information are helpful for determining the danger level of the water vessels/ferries. The water level sensors array and the IMU sensor are directly connected with development board. All the hardware/sensors for developing this system is discussed in section-III. A source program for controlling dataflow and managing the sensors data written in C compiled and flashed on microcontoller's (Wio Tracker) memory. A data SIM is mandatory for maintaining communication between device (in-vehicle) and IoT-cloud.

We have developed a desktop application for monitoring the status of the vehicle (vessels/ferries) in real time. The application collects data from IoT-cloud and visualize it. The snapshot of the prototype application is available in Fig. 7 and dataflow diagram shown in Fig. 8. The application provides all the information about the vehicle (such as Location, load info, orientation etc) through pop-up sliding notification. It also provide alert notification if any vehicle's is in danger (disconnected from the system or unstable orientation or overloaded information etc.). An user/admin account Id and credential is mandatory for accessing the monitoring system.

Fig. 7. The Desktop application for ground/control station. The application collects the data from cloud and visualize them continuously.

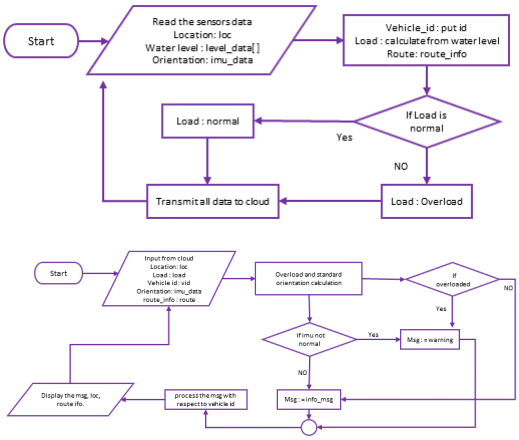

Fig. 8. The dataflow diagram of the system both device(top) and desktop application(down).

V. Result and Discussion

We have successfully tested our prototype version of the system. The resulting sensors data are shown in Fig.9. The

he Table.II depicted the pairwise comparison among existing system with our prototype system.

VI. Conclusion

River ferry capsizes in Bangladesh, killing people every year. Sinking of a capsized vessel which results in worst incidents or accidents are always unwanted and unexpected. Most of time vessels are overloaded, and they continue to move during rough weather without obeying the weather notification. Hundreds of people die each and every year in ferry accidents.

This paper presents a monitoring system which may reduce such incidents by continuously tracking the location of vessels and to keep informed about the situation so that any kind of emergency as well as causes that was marked for occurring accidents like collision and grounding to the authority. This aims to help from destroy of goods as well as lives of people drastically.

Appendix

What is IoT

The IoT or internet of things which is an emerging technology. IoT was first proposed by Dr. Ashton (MIT professor) in the middle of 1999. Professor Ashton discovered the IoT (also known as emerging technology)during his research study on RFID (Radio frequency identification). Any electronic devices or embedded system performs the communication among them through IoT. The most popular three layer architecture of IoT is presented in Fig. 10. IoT has three layers namely, ***Perception layer, Network layer and Application layer***. Electronic devices,embedded systems or things all are connected to the through perception layer. The main task of network layer is data transmission among things or devices. The bridge between IoT and human is established by application layer. More details technical descriptions along with applications domain of IoT are nicely listed in [24]–[26].

Development of An Android Based Real Time Bus Tracking System

Mohammad Nazmul Hasan and Md. Sharif Hossen

Department of Information and Communication Technology
Comilla University, Comilla, Bangladesh
nazmulhasan5793@gmail.com, sharif5613@gmail.com

Abstract—In this dynamic life, everybody is in an urgency to reach their destinations. In this case, waiting for the buses is not feasible. People who depend on the public transport system should know about the location of the bus for which they are looking for. With the advancement of technology, android smartphones have become universal and affordable for all. Smartphones have vast capabilities to provide rich user experiences with interactive facilities. In this paper, we propose a real-time bus tracking system for the students using Android smartphones which can be used for tracking and positioning of the buses by using Global Positioning System (GPS). This android based real time application enables the students to find out the exact location of the buses so that they will not get late or will not arrive at the bus stop too early. It provides the exact location of the student's respective buses which can be viewed on the google map. In addition, this application also gives the information like bus details, driver details, contact numbers, routes, etc. Therefore, our developed application saves the student's time to wait for the buses as they can know their current location of the buses updated every moment in the form of latitude and longitude on Google maps.

Keywords— GPS, google map, android, real-time, vehicle tracking

I. INTRODUCTION

Nowadays, buses are used rapidly as a transportation system in the different organization, e.g., school, college, university, business firm, banks, etc. But, with the increase of population, vehicles are increasing day by day which is further leading to heavy traffic. There are many reasons for heavy traffic in developing countries like Bangladesh which results in more delay to reach at the destination of the respective buses [1]. These reasons may be harsh weather, traffic conditions, etc. [2]. On the other hand, at the bus station, most of the time people have to wait for the arrival of buses because of the delay of a particular bus at a particular stop [3]. Therefore, an effective transportation system has effective movement of vehicles and people which leads to better quality of life and better economic growth of the society. Hence, the bus tracking system can be useful for passengers which will provide the location of the buses with routes using Google map at the current time [4]. Embedding the equipment in the buses to track those is important which increases the cost of the system. Hence, we use IoT based technologies to reduce the costs of processing and communication equipment [5]. Today smartphones are a very good source for tracking the vehicles (i.e. buses in this case), called mobile tracking system [6], because of giving the real-time location of the buses with the help of Global Positioning System (GPS) [7]. GPS uses satellites to locate the presence of smartphones using the values of longitude and latitude. Using those values of GPS coordinates our developed application will show the location of the smartphone used in each bus carried by the driver [8]. Users (i.e. students, teachers, etc.) can retrieve information relevant to the arrival time of buses with respect to the current location by selecting the bus number through the android application [9]. The main objective of this research is to notify the locations of the buses from anywhere for the students so that they do not need to wait for their buses at the stops for a long time and save their valuable time. To complete this, we develop an android application and demonstrate the location of the bus at the particular time.

The remainder of this paper is arranged as follows: Section II discusses the related works with the proposed system. Section III gives a brief of the technologies used in the proposed system. Section IV discusses the architecture of the proposed system and its specifications. Section V includes the step by step experimental analysis and discussion. Section VI summarizes the conclusion with future works.

II. RELATED WORKS

Bus tracking systems are developed to display the exact location of buses which can be useful for the public transport system. The system requires an internet connection and may or may not be GPS tracker. Real-time bus tracking system using GPS displays the current locations of the bus which consists of a GPS tracker, real-time server, and the user application. It provides relevant bus routes and other information to the user. Bus tracking system uses the built-in GPS service provided by the Android. A smartphone is used on each bus and gets its GPS coordinates. These coordinates are shifted to the server. Users can retrieve information through their Android application. Then, selecting the respective bus number, users receive the arrival time of the bus with respect to the user's current location. Google map is also used to graphically plot the bus location [10] [11].

There are about 17,000 location-based applications on the marketplace. Some apps can make our traveling a little easier, a bit more fun and more memorable. But, most of the applications are hardware dependent. There is a fact of high cost as the devices they use are costly and there is more complexity in the integration of those devices in a single unit [12] [13]. To fix such problem is also costly and time-consuming. In this research endeavor, we develop a real-time android based bus tracking system which is hardware independent, less costly and easy to install.

III. Technologies Used

A. GPS Technology

GPS [10], also known as a space-based radio navigation system, consists of 24 satellites orbiting this earth under the management of the US government. It was primarily developed for the military purpose and later used to help general people for various applications, e.g., navigation, tracking, timing and positioning services [14] [15].

B. Android Platform

Android is a Linux based open source operating system which was founded by Andy Rubin, et al [16]. There are some important features that make android different from other operating systems [17]. These are as follows:

- Open Source
- Easy to customize the Android platform
- Support the multiple inheritance since it uses the concept of Java [18]
- Allow all graphic dimensions, i.e., 3D and 4D
- Support the low-level interface for having a Linux operating system kernel
- Support standard libraries like OpenGL, Web Kit and SQLite, etc.
- Appealing look-and-feel features including live Really Simple Syndication (RSS) feeds, weather information, etc.
- Support many more connectivity and messaging services like Bluetooth, GSM, Wifi, MMS, SMS, CDM, etc.

C. Firebase Server

Firebase is a web and mobile application developing platform that provides tools and services to develop real-time apps. It was developed in 2011 by Firebase Inc. and in 2014 acquired by Google. It provides a backend and real-time database as a service. It is a cloud-hosted database system [19] [20].

D. Google Map

Google map is a free software that renders 3D graphics of earth using satellite images around the world. It is a version of Google earth that shows the maps and can be embedded into web pages through Google maps API [21].

IV. System Design and Specifications

Our proposed and developed android based system provides the students to find out the exact location of the buses from anywhere. The bus routes are shown on the user interface displaying the position of the buses using google map. Accordingly, user can plan and start. The advantages of the developed system are to:

- Provide the exact position on Google map
- Show the details of the buses from anywhere
- Provide details like bus number, drivers' contact number, bus route, stops, etc.

Figure 1 shows the architecture of the developed system. The system consists of a client and a server interface. The developed android application is used on both driver and user module. The user can track the location of buses controlled by a driver on Google map from the server using GPS. Admin maintains and updates all relevant information like bus routes, driver number, number of buses, etc. on the server.

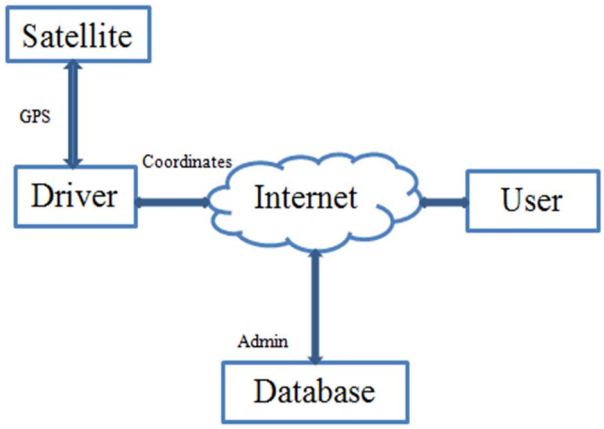

Fig. 1. Block Diagram of System Architecture

The developed system contains the three modules:

a) Driver
b) User
c) Admin

a) Driver Module

This module is designed for the bus driver. The authorized bus drivers can use this module by providing their unique login credentials. They need to start their location services before driving. The current location of the bus will automatically be updated from the driver's mobile to the server every moment in the form of latitude and longitude. Figure 2 shows the flow diagram of the driver module.

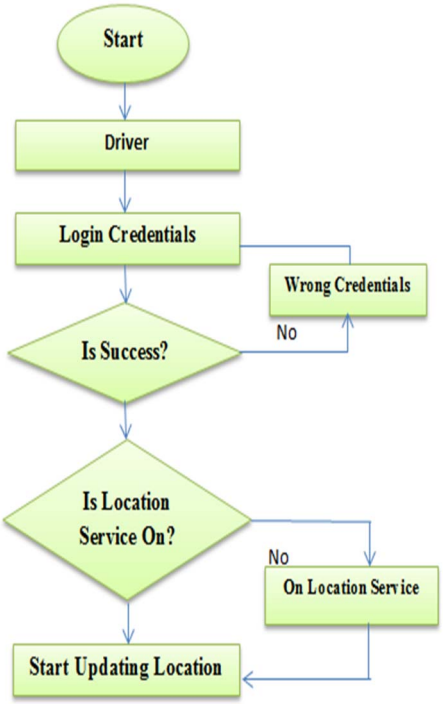

Fig. 2. Driver Module

b) User Module

This is the most important module and the soul of the system. Users of this module need to click on the user button. They can access the details of all the buses through their smartphones. Here, they will get all the buses and driver-related information offline too. Students can track the location of their buses from any location. A student must make sure that their location service is active. Figure 3 represents the flow diagram of user module.

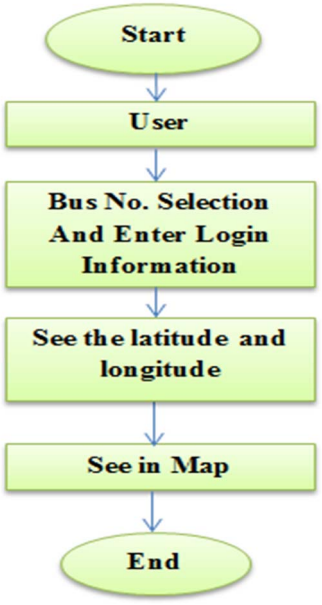

Fig. 3. User Module

c) Admin Module

Figure 4 shows the flow diagram for the admin module. This module is designed for the bus administrator for updating the information. Admin can log in to the admin account after authentication and authorization. He can enter new route details and also he has the options to add or remove a route. The authority has the right to update the driver's name, driver's contact number, routes, stops, etc. If the admin wants to send any information to the driver, then he can send the message to the driver's mobile.

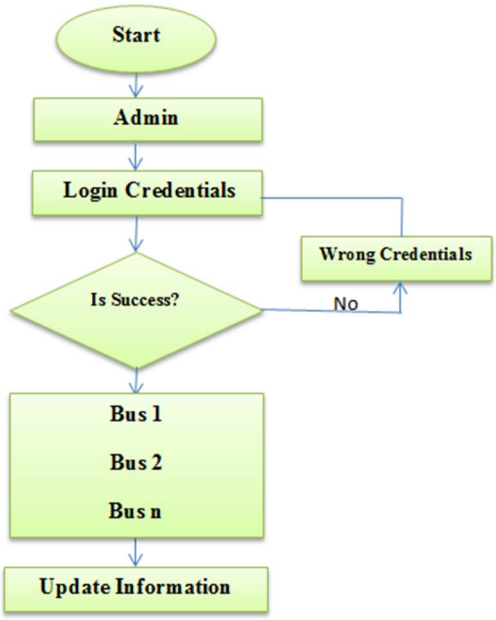

Fig. 4. Admin Module

V. Experimental Result and Discussion

When a driver enters into the driver module, Figure 5 will be appeared for the driver to enter his login credentials. The location of the bus will be shown on the screen as latitude and longitude and it will automatically be updated in every 5 seconds (shown in Figure 6).

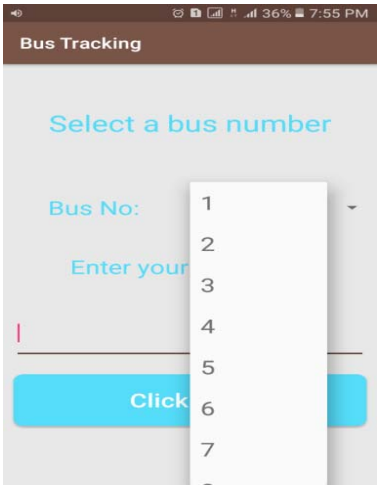

Fig. 5. Driver's Bus Selection

Fig. 6. Bus Location

To search for a bus location a user has to enter the bus number and login credentials. Then, the map will be displayed which will show the current location of the bus. They can get access to the details of all the buses through their mobile phones. Here, they will also get the bus and driver-related information as shown in Figure 7.

Fig. 7. Drivers' Details

When the application is launched, home activity shows the user module. When a user selects this module, another activity will be opened where the user will select the bus number and enter the login credential shown in Figure 8. Then, the map will be displayed which will show the current location of the bus as shown in Figure 9.

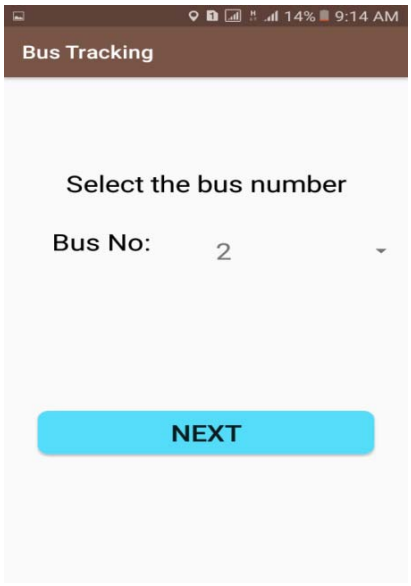

Fig. 8. User's Bus Selection

Fig. 9. Bus Location on Map

VI. Conclusion and Future Works

In this research study, we design and develop a real-time bus tracking system using GPS tracking technology which needs only a smartphone and a real-time server. Our application consists of two fundamental concepts: first it collects the real-time location information of buses via GPS technology and secondly updates the location information in the database server. The bus-side, server-side and client-side modules provide all the expected functions. Since this application does not need any external hardware except a smartphone which is available to anyone in the world, the overall cost is very low or no cost needed for tracking the bus location. It provides nearly accurate data in real time that makes possible for the user to track the buses.

In near future, we would like to enrich our proposed application by adding the following features.

- Designing a reliable server with a user friendly API
- Distance and time calculation between two places
- Anti-theft system for cars and bikes
- As a vehicle management software for transport companies

***Abstract*—Medicinal care signifies as a standout amongst the most striking application ranges for the IoT. Hospitals utilize new advances and IoT to screen the situation of patient's therapeutic conditions and other related data. There are vast IoT applications that are being readily used in the medical care nowadays from. It can possibly keep patients safe and sound, as well as it will enhance how doctors provide care. Thermometers, electrocardiograms, ultrasounds, glucose monitors, and more are altogether beginning to end up associated and giving patients a chance to track their wellbeing. This is significant for those circumstances that require line up meetings with specialists. In this study, we presented a preliminary healthcare system for the treatment of Chronic Kidney Disease (CKD) or Chronic Renal Disease patients with the concept of IoT, which includes patient log, the nutrition of the food basically focusing on the level of salt intake, monitoring the sleep pattern, activity level, water intake and so on in order to provide with required improvements needed for the betterment of their health condition. In addition, the data and information obtained from the patient log and from their activities will stored in cloud for future purposes and simultaneously it can be accessed directly by the caregivers for monitoring of a patient's health condition.**

I. INTRODUCTION

Internet of Things (IoT) is a method for interfacing gadgets to the Internet and to one another utilizing remote innovation. This enables engineers to add innovation-based highlights to physical gadgets including the capacity to convey encounters continuously. It is a prominent articulation, which is conjectured as a standout amongst the most encouraging advancement drivers for automation and control in the business. The Internet of Things (IoT) has moved toward becoming the industry-skeptic language to portray how innovation is as of now been inserted in numerous business sectors, including medicinal services, and developing the manner by which business is directed. By 2020, it is projected that 200 billion gadgets will be associated, which measures up to 26 smart gadgets for each individual on Earth. The cumulative market capability of IoT invention will reach at its peak with 38% of the cumulative value originating from gadgets in health care [2]. The IoT has several applications in medical healthcare, from remote intensive care to smart devices or sensors and medicinal device incorporation. Moreover, IoT can properly recognize ideal occasions for restocking supplies for various gadgets for their ceaseless and smooth activity**.** It has the possibility not only retain patients healthy and safe, but to expand how medical doctor provide care additionally. Healthcare Internet of Things can also enhance patient satisfaction and engagement by providing patients with more interactive time with their consulted doctors. The capability to track patient's location and therapeutic equipment by means of sensor-based expertise has shaped a service of its own that is currently known as LaaS (location-as-a-service). Few of the instances consist of tracking of therapeutic devices that is used to examine patient's condition and their location with the help of geo-tracking in order to provide emergency medical aid which do leave a huge impact for the patients in need. Consequently, imaging, diagnostic devices, and various therapeutic sensors can be perceived as smart things establishing a fundamental factor of IoT. Healthcare built using IoT features is projected to reduce expenditures, increase the duration of life and improve the involvement of users. The added benefit of healthcare is bulk amount of statistical data. But the security of those collected statistical data must be ensured.

However, in developing and developed states, chronic diseases are rapidly growing such as cardiac diseases, diabetes and renal or kidney disease. 30 million of adults are projected to be diagnosed with CKD (Chronic Kidney Disease) and furthermost most of them are not aware of it. Risk influences for renal disease consist of high blood pressure, diabetes, obesity, heart disease and family background [1]. The administration and analysis of Chronic Renal Failure or kidney disease are complex. The hazard related with the absence of knowledge, weak management, and impassive way of life can be considered as essential explanations behind growing certainty of chronic kidney disease on the planet. Chronic kidney disease is escalating the damage role of kidneys over interval of years or months. CKD is determined by the occurrence of damaged or decreased kidney, glomerular filtration rate (GFR), where GFR < 60 ml/min/1.73 m2 for three months or so. Such deterioration is difficult to excess and waste fluids development in body and has an impact on its performance, possibly projecting to complications. It remains undiagnosed and overlooked until the state of the patient becomes worse gradually over time. Nevertheless, in order to have a healthy lifestyle, an individual need to have appropriate information about sustenance, a realization of hazardous diseases and so on. Accomplishment of such system needs an active contribution and involvement of users.

In this study, we proposed a healthcare system that will be beneficial for monitoring the health condition of chronic kidney disease patients with the help of smart devices such as wearable's. Section II consists of background study and related works. The design and the construction of Healthcare System for CKD patients have been delineated in Section III. The investigational design has been studied in Section IV. Section V illustrates the outcomes or results and finally the paper draws the conclusion in section VI.

II. Related Work

eHealth (Electronic Health Record) can be treated as a part of biomedical engineering, which is technologically advanced to help therapeutic procedure to expand the value of life by improving public healthcare [3]. In paper [4], the author correspondingly projected that if IoT is applied in the eHealth then will play as the leading role in the upcoming future.

Numerous researchers have endeavored to execute IoT for health care utilizing Raspberry Pi [5] [6]. Some study on Internet of Things (IoT) for healthcare tried implementing the system to reduce the morality rate of mother and an infant. In India, a system was developed known as Mother and Child Tracking System (MCTS), which was used to simplify universal access to such health services. It provides and help the healthcare providers with their facilities. In [7] the developers build a system based on smartphone for remote real time tele-monitoring of patient's physical activity with chronic heart failure (CHF). The tele-monitoring system was designed to measure patient activity minute-by-minute and energy expenditure (EE) estimated from accelerometer. In addition, the system tracked relative user location via global positioning system (GPS) to track outdoors activity and measure walking distance and also administrated self-reported vital and relevant cardiovascular symptoms. However, the drawback of the system was that it consumed a lot of battery life as some execution was done in the phone and the data was being collected from many sensors, in result it had an effect on usability.

Convolutional Neural Network (CNN), which is a special architecture of artificial neural network is now widely used for image classification. For the work in [8], the authors have used Deep Convolutional Neural Network to detect object with the data size of 1650 food images and epochs of 25. They had achieved 60.74% of accuracy.

The authors in [9], designed a mobile health (mHealth) self-control of diabetes that supports real-time clinical communication and response personalized to the individual necessities of the diabetes patient, using current and past patient records. Physical layer nodules are associated to a Network centered application layer over a present telecommunication infrastructure. It connects the several objects to other objects in the physical layer. The application units, that handles all clients associated functionality, is planned to be adaptable with the Model-View-Control (MVC) outline. Depending on the gathered readings, the cell phone delivers the support and required opinion in measuring the necessary insulin bolus. The researchers at [10] proposed a wireless living assistance IoT based system for elder people to monitor and register patient's important information to provide mechanisms for triggering alarms in case of emergency situations. The research suggests a system including wrist band which can be connected to a cloud server for assisting and monitor elderly people. The researchers claimed it as cost efficient with low power consumption system having wireless communication features.

III. Health care System for Chronic Kidney Disease PATIENTS

The framework in fig 1. uses MQTT, which is a frequently used protocol in IoT projects, and it stands for Message Queuing Telemetry Transport, as it is a lightweight messaging protocol which utilizes operation to interchange data between clients and the server. Additionally, less power consumption, optimal data packets, and simplicity of implementation contributes in the betterment of the health care system. Similar to internet protocol, MQTT is based on client and the server, where MQTT acts as the server that is use to handle the client's requests of sending or receiving data between the connected devices. Thus, it is used to establish communication between patients and care providers in order to provide an affluent healthcare facility.

The proposed framework makes it possible to provide superior medicinal services management with a scope of various modules. Our framework lies on end clients who are utilizing a mobile application, a cloud as a service and a web-based interface for health care system. The majority of the clients are associated with the end goal to keep up an astounding correspondence benefit. The framework includes various modules such as: - *(1)* Patients log to record one's data, *(2)* Sleep pattern module to uphold the sleeping cycle of the patient as it plays as a vital role amongst the CKD patients, *(3)* Water intake that will notify the patient to stay hydrated, *(4)* Food classification which will provide patients with the nutriments of the food in order to precisely check on the amount of potassium, sodium and other nutrients that he or she intakes on a regular basis as the intake of salt, *(5)* Patient's physical activities which is used to ensure that a patient is not living an inactive life and this is done by the movement detection with the help of smartphone sensors or a wearable. The majority of the previously mentioned modules will be capable enough to deal with the medicinal services administration of a CKD patient in the near future.

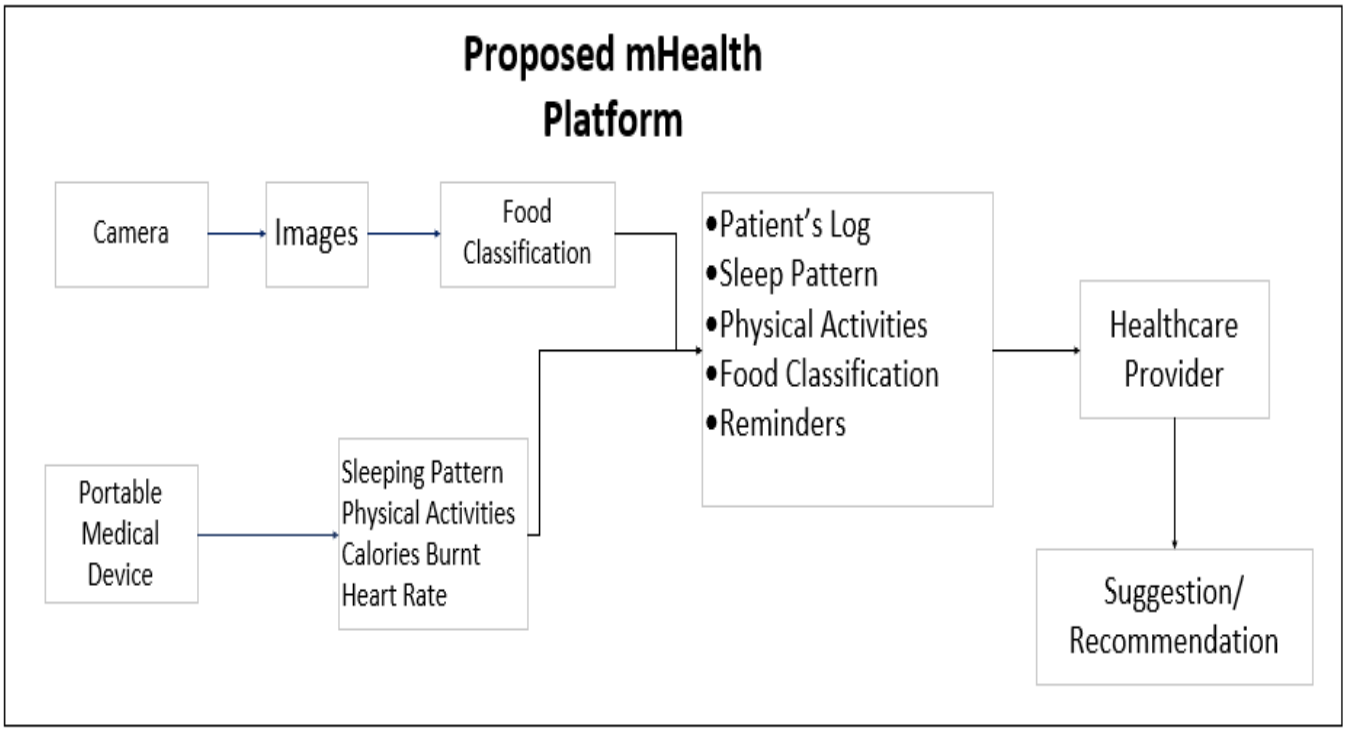

Fig. 1. Framework of the proposed healthcare system

A. *Patient Log*

A computerized health care system to record patients' information and basic statistics of the patient, such as name, daily intake of water, previous records of dialysis or transplantation, current stage of CKD if any, this information is stored in cloud storage for future purposes, which allows programmed monitoring. Patient logs are basically helpful to monitor patient's condition which is a significant issue.

B. *Sleep Pattern*

Sleep issues are a typical affliction for most individuals despite the fact that sleep is a vital factor amongst the most critical factors in keeping up both emotional health and physiological. A proper sleep is very important for general health, in other words, the kidneys. The function of kidney is usually regulated by the sleep pattern. People who sleep less have a faster decline in their kidney function and nighttime patterns affect CKD.

Patients with chronic kidney disease have problems staying asleep and falling asleep. If a patient has a habit of consuming too much caffeine, reducing the intake can help to have a better sleep, as caffeine is a stimulant it changes the sleep cycle. Therefore, to monitor the sleep patterns for CKD patients we will be using a wearable or smart fitness tracker to track the sleeping pattern it monitors the movements. When the device is synced then the subsequent morning, the software decodes those activities and movements into sleep statistics. And the technique of tracking movements by means of a device to measure the cycle of sleep is known as actigraphy.

Actigraphy nowadays have movements (accelerometers) as well as an adequate memory to store data for few weeks. Movements are examined a few times each second and analyzed later on. The remarkable component of actigraphy that separates it from early innovations is the capacity to connect the gadget to the wrist (or lower leg) of a person for a long time and give movement information continuously.

C. *Water Intake*

Keeping an account of water level is important for Chronic Kidney disease patients. Water intake varies with different stages of CKD. Hence, maintaining the water level consumption is a crucial factor for CKD. There is presently a proof on the particular impact of high-water consumption on the kidney. [13] Increased water consumption has been appeared to decrease the threat of kidney stones and lower the chances of forming stones. But at the point when the kidneys fail, individuals don't discharge enough water. For the individuals who are accepting dialysis treatment, water intake should really be extremely limited. Thus, to notify patients to stay hydrated, we are using Webhooks services. This will integrate the services on IFTTT (If this then that), where one can build Applets that will work with any app or device which can send and receive a web request. From the changes, that takes place inside other web facilities, for example Facebook, Gmail, Instagram etc. Applets incorporate sending messages to Messenger from the Google Assistant, getting estimates by means of Weather Underground, along these lines; the conceivable outcomes are relatively inestimable with a touch of creative ability. Here, in this study, the IFTTT bot on Messenger was utilized to notify the users to accomplish something as straightforward as a glass of water every 4 to 5 hours.

D. Food Classification

Pictures using smartphone camera have been used to measure the nutrients of the food. In particular, Patients with CKD cannot remove excess of salt so it is crucial to maintain the intake of salt. Excess of salt can cause swelling of hands, ankles, feet, breathing problems, increased blood pressure, etc. Therefore, balancing salt level is important in CKD [14].

To enlighten users about the nutrients their foods are having we will be using Convolutional Neural Networks that is referred as CNN, which is a kind of Artificial Neural Networks that is recognized to be vastly potent within the field of image classification and identification [15]. CNN performs the four following steps: -

(i) Convolution: - The most utilize of the Convolution operation in case of a CNN is to recognize suitable features from the picture, which is an input for the primary layer. Spatial interrelation of pixels is maintained by convolution. It is done by utilizing tiny squares of picture by achievement of picture features. Formula for convolution is given below:

$$I_{new(x,y)} = \sum_{j=-1}^{1} \sum_{i=-1}^{1} \alpha_{ij} I_old(x-i, y-j) \quad (1)$$

(ii) Non-linearity: - Rectified Linear Unit (ReLU) that is a non-linear procedure. It acts on a basic level. ReLU is a process that is done per pixel, which then surpasses all the negative numbers of every pixel by zero in feature map. It is mainly a smooth estimate. (1+ex (x) = lnf).

(iii) Sub-sampling or Pooling: - Spatial Pooling that is additionally called down sampling or subsampling helps in decreasing the scale of every feature map however even whereas doing therefore, retains the foremost important info of the feature map. Once pooling is completed, ultimately the three-dimensional feature map will be regenerated to at least 1D feature vector.

(iv) Fully Connected layer (*Classification):* - The outcome of pooling operation and convolution give noticeable feature that are removed from the picture. The features are then used by FC layer for lowering the input picture into distinctive classes centered on training dataset.

E. Physical Activites

Physical inactivity causes a decrease in daily activities of day to day life and nature of life. [16] By improving the quality of their bones, joints, and muscles through working out, individuals with CKD can enhance their coordination and balance. This can additionally avoid the patients from falling also, secure their autonomy as they age. Also, it is broadly realized that CKD patients are at high hazard for unexpected death because of heart disease due to some degree to their inactive behavior. [17]. By expanding the physical activity levels of people with CKD, it is conceivable to reduce their danger of heart disease and enhance their physical working, thus decreasing the risk of unexpected death [18].

In this case, a portable medical device or sensor such as accelerometer will be used to constantly monitor the activities of the patient's body taking place in an accelerometer of 3-axis. The statistics are logged every nanosecond starting from the time the wearable is worn, which allows it to trace if an individual is running fast, walking forward even standing without any motion.

All these statistics are stored for further processing. This processing happens when the information is exchanged to the product related with the wellness tracker on the cell phone or PC for matching up. Since the individual has officially imparted individual points of interest to the product, the information gathered is gone through a customized calculation. This makes it feasible for the product to recognize what the distinctive developments recorded really suggest. It orders the developments into various exercises and afterward creates more data dependent on these points of interest. These are generally put away under various headings in the wellness tracker application. At the point when the individual taps the application a wide assortment of data is accessible from the handled information, prepared for perusing. The application lets the user know the count of steps that is taken, the rate of speed, the individual's pace, and also the number of calories liable to be scorched. The application enables the person to communicate with the data in an easy way.

IV. Results And Experimental Design

A. Data Collection

Data received from the patient's log, sleep pattern, and physical activities are collected. After collecting the user records, the application makes a calculation on each user and takes necessary actions. Incorporating the app of end client and web-based interface together with cloud help in this process.

B. Experimental Design

An android-based application was developed using Java and web portal of the mHealth was built using PHP. Notifications and reminders were triggered combining IFTTT (If This, Then That) and Facebook Messenger. The entire system was hosted using cloud storage, as the data are stored in cloud, henceforth no further trouble of uploading and downloading data were needed. Additionally, when the healthcare providers, which is a doctor or any medical specialist receive the patient's data, she/he further evaluates the information and addition steps are taken and suggestion or recommendation are given based on the severity of the patient's condition.

Fig. 2. The sleep pattern of a patient with the help of wearable in this case Fitbit.

In Fig. 2, the level of sleep and the wake duration are determined by utilizing computer programs, for example, time of total sleep, percent of time spent sleeping, time to wake, and percentage of total time staying awake. It monitors the activity of brain rather than counting number of turns.

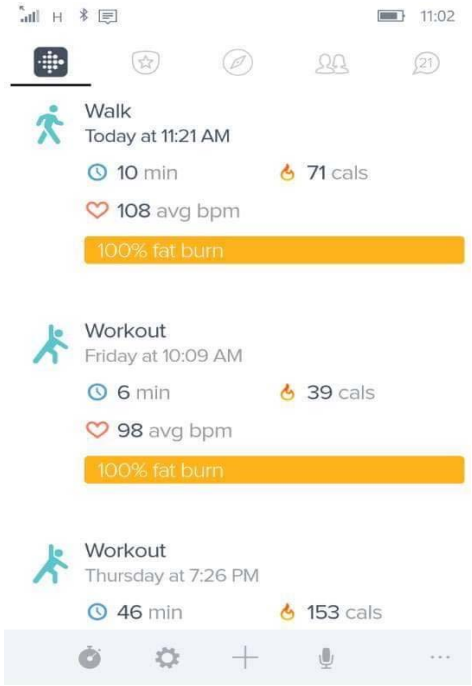

Fig. 3. Walking and workout sessions of a patient on the following days

Daily Physical activities of a patient is recorded using Fitbit, where the wearable sensor such as optical sensor calculate or record the frequency, acceleration, intensity, outlines and duration of a patient's movement. It takes a good bunch of statistic which helps a track whether one is just walking or just using hands to wave someone goodbye. In Fig.3, it is shown that the patient was walking for good 10 minutes and was working out as in was doing some light exercises for 6 minutes and 46 minutes on the following days respectively.

Due to the complexity of the system, efficient tools and technologies was used to simplify the entire infrastructure. An app has been build using Java Alerts and notifications have been implemented with the help of If This, Then That (IFTTT) and Facebook Messenger combining together. A shown in the Fig. 4, the reminder to stay hydrated was geenrated after every 4 hours interval.

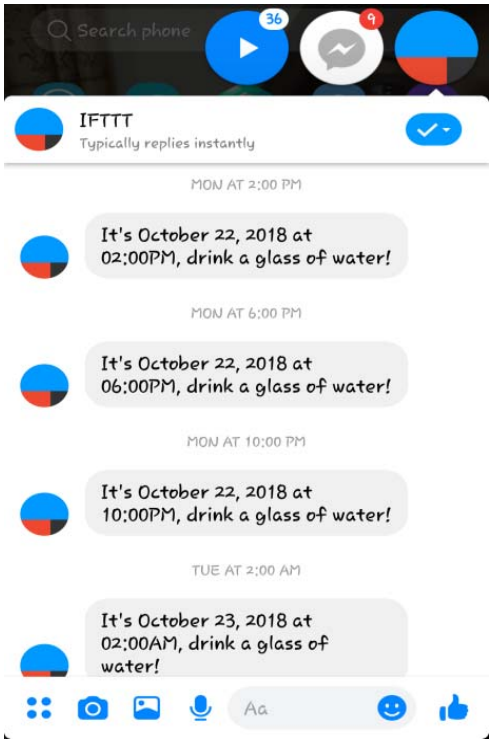

Fig. 4. Daily Reminder to drink a glass of water

C. *Results*

In our model, we used IoT and deep learning technologies. To analyze the nutrients in the food we used Image Recognition. Where the dataset was built with different type of food from existing online repositories. Furthermore, using Convolution Neural Network, the outcomes obtained were as following.

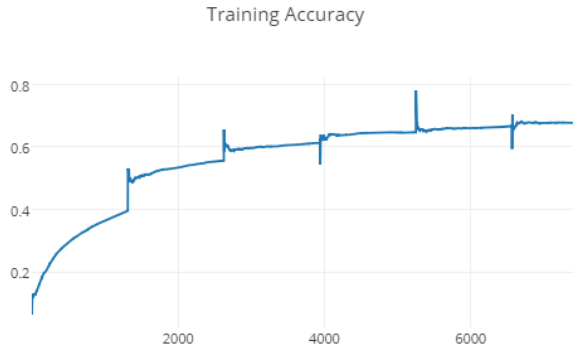

Fig. 5. The training accuracy (67.6%)

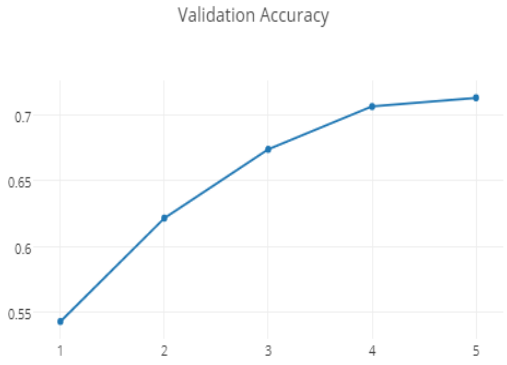

Fig. 6. The validation accuracy (72.8%)

Here, we are using **Deep Learning Studio**, which is also available in cloud solution. It is an individual user solution for deploying and creating Artificial Intelligence (AI). The basic interface causes any user to plan deep learning prototype effortlessly. Pre-learned models and in addition built-in assistive highlights streamline and speed up the model improvement process. We used our food dataset and modified the model with the visual interface. The stage consequently spares each model form as repeat and tune hyper-parameters to enhance execution. The model achieved a training accuracy of 67.6% and validation accuracy of 72.8%. Comparing to other existing system previously which also used CNN, our model could provide better result.

V. Conclusion & Future Work

Internet of things (IoT) has been separating different conventional figuring techniques in all field particularly healthcare. In IoT healthcare industry the idea of remote checking, the condition of patients' is a different break-through. The proposed model is developed to be of low-cost and more reliable particularly for CKD patients with real-time monitoring system, which is online based. The system is designed to monitor a patients' vital information. Various device and sensors are used here for the monitoring purpose. The system consists of a patient log, sleep pattern, level of water and salt intake, nutrition information mainly based on salt. All the data collected from the patients' log are stored on the cloud, which can be later used for, further changes, and generate an overall report for further analysis. The system is therefore not only helpful for patients but also for nephrologists and renal dieticians. Finally, the proposed model was successful to provide visions regarding renal conditions.

For future enhancements, a knowledge-based agent will be designed using intuitionistic fuzzy theories, which will be playing the role of healthcare provider, as a doctor will not be able to respond 24*7. More descriptive work for each module will be covered, such as custom-made mobile portal, wireless body sensor to monitor a patient's blood pressure will be introduced as hypertension can be the progressive cause of chronic renal disease.

***Abstract*—With the first growth of population, the protein demand in the world is also increased that can't be overcome by meat. Fish is a great source of protein even low-cost comparing with meat. Traditional fish farming and most of the existing smart system fail to produce the expected level of fish. This research paper demonstrates an IoT based Ideal fishery that will be low in cost and high in fish production level. A microcontroller is engaged in measuring several essential features of the water like pH, temperature, water level, oil layer and the fish behavior to understand their hungry level that directly affects in the first growth of the fish. The user will be notified of the information through our developed mobile app and an interactive web interface. Bluetooth and ESP8266 wifi module are integrated with the system to deliver the data to the mobile app and web interface. In case of any abnormality detection, the system informs the user to take the immediate steps. Besides, forecasting of the several water parameters in the following day to take an earlier preventive action makes the proposed framework more exceptional. In consequence of this feature, the system will assist the fish farmer to produce more fish, and the protein challenge for the large population will be diminished drastically.**

Keywords— fish farm, pH sensor, oil layer detection, Support Vector Regression, Random Forest Regression

I. INTRODUCTION

The present 7.3 billion world population is estimated to be 11.2 billion in 2100. With the first growth rate of the current population, at least 70% more protein will be necessary in year 2100[1]. Oceans, a great source of protein, is taken about 2.5% more fish than what ocean can naturally support[2]. WWF (World Wildlife Fund) reported that since 1950, 90% of very usually captured fish have vanished from the ocean[3]. We are increasing stress on the ocean that's a threat to the natural balance. To meet the demand, an alternate source should be though without threatening nature. According to a report by FAO, aquaculture has experienced a significant annual growth rate of 7.4% with escalating meat requirements[4].

Aquaculture-based fish farming is an excellent solution to this crucial problem. Fish farming is very cheap as only 1.5 pound feed is needed to produce 1 pound fish while in case of meat from cow its 8-9 pound feed and 8000L water[5].In respect to financial gain, a significant difference between IoT based fish farm and non-IoT based fish farm has been found on a study of Zhang et al. [6].The performance of the fish relies on various factors: production factors [7],environmental factors [8],and biotic factors [9].It is possible to monitor and control some of those parameters.

The primary objective of this work is to develop a low-cost smart fish monitoring and controlling system that can measure different important water characteristics like pH, temperature, oil level, water level, and fish hungry level by observing the fish behavior. Several low-cost sensors are equipped with the system to accomplish the assigned task. To achieve an accurate value several data manipulation techniques like mean, mode, data normalization has been followed. The gathered information is stored in the cloud server for further analysis like forecasting the probable pH, oil layer, water level, required fish feed etc. to take advance preventive steps. If the parameters exceed the predefined threshold level, then the system will notify the user through the mobile app. Also, the Bluetooth module is used to update the data in the mobile app for a local user. To develop the system only $50 - $55 is required. This amount is so low cost that a fish farmer can easily adapt it and take part in resolving the world protein challenge problem.

This paper is structured into five sections containing the introduction. Section II presents related work. Section III combines methodology where circuit design, smart fish monitoring, and controlling process is explained. An experimental result is shown in section IV. Section V The conclusion and future work are deliberated in section V.

II. RELATED WORK

A few researchers from the genetic engineering field produced genetically modified fish having more breeding capabilities. But their survival rate and nutrition level are lower than the natural fish[10]. Also supplying artificial fish feed containing more chemical, microbes, seaweeds, etc. causes various disease. Alternate fish feeds are developed having lower chemicals to control the diseases.

Nowadays, Internet of Things (IoT) makes a revolutionary change in diverse fields. In consequence of this revolution, IoT improves the fish farming system that resolves a large portion of the nutrition problem for more growing population[11]. Conventional fish farming faces a lot of difficulties in the change of the climate like heavy rainfall, extreme weather,

limited water in the farm, high temperature, etc. FAO highly recommends that modern technologies should be integrated with traditional farming to overcome the challenges. SK telecom developed an IoT based fish farm system that observes pH, temperature, dissolved oxygen and notify the fish farmer in real time through their smartphones[12].To test the water quality, the conventional method takes several samples from various locations and process in the laboratory. To smart this method, Shareef et al. [13]presented an IoT based decisions support system using WSN (Wireless Sensor Network) technologies that determine various physic-chemical characteristics of water and inform the end user through smart mobile. Daudi et al. also developed a fish farm monitoring system to examine water quality based on WSN technology[14]. Their equipped sensors collect temperature, oxygen level, pH, water level of the fish farm and transfer the data to the mother server via ZigBee protocol. Raspberry Pi based system continually determine the water quality through equipped sensors and store the data in a cloud server for further analysis[15]. If any water parameter exceeds its threshold level than an auto-generated message will be sent to the user. They utilized Lab View software to show the gathered information. But the high cost is the main drawback of this system.

A three-layer architecture-based system is proposed where a remote layer collects the data, server layer transfer and store the data. The obtained information is displayed in the client layer[16]. The software is also integrated with the system to monitor the sensor data. The proposed IoT based system of Cesar Encinas et al. deployed Arduino, Atlas pH prove digital sensor, dissolved oxygen probe, analog temperature sensor, and a ZigBee module to transfer the data into MySql database[10]. They also used 200 mA/h rechargeable batteries lasting for 8h. The system for fish farm monitoring system determines similar factors instead of considering other essential considerations like the density of the oil layer. Besides, most of the work doesn't identify which sensors they have employed or equipped high-cost sensors that make the system difficult to cope up in the fish farm. Moreover, most of the system supply the fish feed after a certain period ignoring feeding when they required. Prediction of the amount of next week fish feed is missing in most of the system.

In the context of Bangladesh aquaculture system, lots of fisheries follow the traditional methods to cultivate the fish. As a result, the cost becomes high, but the output is not at an expected level. To the best of our insight, this is the first attempt to develop a low-cost fish farm monitoring and understanding when fish require feed by analyzing their movement. Also, the forecasting features of the next week fish farm parameters willhelp the fish farmer to take a preventive step in advance.

III. Methodology

Figure 1 demonstrates the whole picture of the proposed IoT based fisheries monitoring and controlling system, how the fisheries information will be gathered and how transferred to the end user of the system. The system estimates several parameters of the water like pH, temperature, oil layer, water level and the movement of the fish that directly effect on the quick growth of a fish. After supplying the power, the system is activated. At the first time launching, to measure the targeted water parameters and fish movement, the system takes a few moments to initialize the equipped sensor. As pH sensor doesn't give a proper reading at a static situation, it needs to shake slightly to measure the pH of the water appropriately. The system uses a servo motor to perform this task that rotates the pH sensor 30degree in one direction and 30degree in reverse direction. For more accuracy and lower the amount of power consumption of the system, it takes an average of five ph value where each value is read in every 3min. By using equation (1) this average value is calculated where P is the value of ph in every 3min and pH is the desired result.

$$pH = (\sum_{i=1}^{5} P_i)/5 \quad (1)$$

Dense oil layer hinders the fishes to meet the sunlight that reduces the grown of the fish even can cause death. By IR optical sensor, the proposed system measures the density of the oil layer and stores the data in memory. Like pH value measuring, the value of the oil layer is calculated using equation (2) where D is the value of the oil layer in every 3min and Oil layer is the ultimate result.

$$Oil_layer = (\sum_{i=1}^{5} D_i)/5 \quad (2)$$

Usually in a fishery, after a certain period, fish food is supplied to the fishes. But maybe continuously increasing fishes need food earlier than the given time or more food. We know, starve fishes grow very slowly. So, feeding the fish when requires is a mandatory feature of a model fishery. The system can determine either the fishes is Extreme hungry or medium hungry or normal hungry so that enough fish food is supplied. The abnormal movement, i.e. not a frequent movement of the fish can help us to understand the fish hunger level. Three ultrasonic sensors (*a, b, c)* are deployed in this purpose where each ultrasonic sensor takes six value after every 10 sec. For each sensor average value is calculated using equation 3,4 and 5where *a* is a location of a fish measured by sensor *a* and *b* and *c* are like *a*. Then for each sensor RMS value is calculated using equation 6, 7 and 8 $a_rms$is measured RMS value by sensor *a*,$b_rms$and c_rms are like a_rms. From these three RMS value of the sensor, we can determine the hungry level easily. If three RMS value exceeds the threshold value, then the hungry level is extreme, if two value exceed then medium hungry level, if one value exceeds then normal hungry level, if any RMS value doesn't exceed the threshold value then satisfied level.

$a = [a_1, a_2, \dots a_6]$ $b = [b_1, b_2, \dots b_6]$ $c = [c_1, c_2, \dots c_6]$

$$a_avg = (\sum_{i=1}^{6} a_i)/6 \quad (3)$$

$$b_avg = (\sum_{i=1}^{6} b_i)/6 \quad (4)$$

$$c_avg = (\sum_{i=1}^{6} c_i)/6 \quad (5)$$

$$a_rms = \sqrt{(a_1 - a_avg)^2 + \dots + (a_6 - a_avg)^2} \quad (6)$$

$$b_rms = \sqrt{(b_1 - b_avg)^2 + \dots + (b_6 - b_avg)^2} \quad (7)$$

$$c_rms = \sqrt{(c_1 - c_avg)^2 + \dots + (c_6 - c_avg)^2} \quad (8)$$

Too hot and too cold temperature is a great reason for the slow growth of a fish. The system gets the current temperature of fisheries through the temperature sensor. In similar to pH and oil layer value measuring, the system measures the temperature of the fishery using equation (3) where T is the temperature in every 3min and Temperature is the estimated value.

$$Temperature = (\sum_{i=1}^{5} T_i)/5 \quad (9)$$

Similarly, too high and low water level is not suitable for the fishes. A liquid level sensor can measure the water level, but it is costly. To make the system more cost-effective, instead of the liquid level sensor a low-cost ultrasonic sensor is equipped to measure the water level. The system recognizes either the fisheries are in high or low or normal water level. Like previous value measuring water level is determined using equation (4) where W is the water level in every 3min and water level is the outcome of the right-hand side calculations

$$Water_level = (\sum_{i=1}^{5} W_i)/5 \quad (10)$$

Through two communication media, the microcontroller sends the gathered data to the end user. A mobile application and web interface are integrated with the system to operate it easily. Bluetooth module sends the data in the mobile app so that local fishery supervisor can easily gain the necessary information. ESP8266 WIFI module sends the data to the web interface so that one can monitor the fishery remotely. In the web interface, the data is plotted graphically and stored in the database that will help the supervisor of the fishery to check the previous data when necessary. Also, the ESP8266 WIFI module can interact with the mobile app in case of Bluetooth module failure. Also, if the parameters of the water quality and movement of the fish exceed the preset threshold value then buzzer will be on and fishery supervisor can be notified through mobile app also.

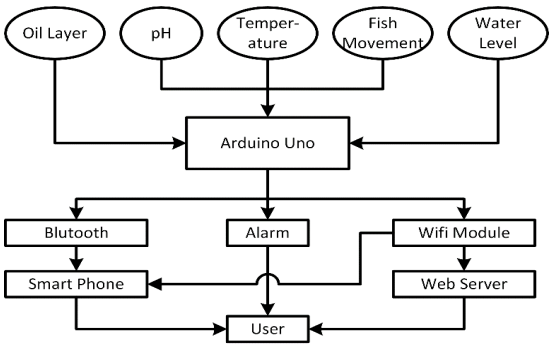

Fig. 1. Block Diagram

The proposed system is classified into the following parts:

A. Circuit Design

The proposed system is developed by following the designed circuit, shown in Figure 2.The ground and VCC pin of every sensor are connected to the ground and 5v pin of Arduino Uno. pH sensor relates to the analog pin of Arduino. From the analog output of the pH sensor, the value of pH is calculated using the formula of pH calculation. Servo motor, buzzer, temperature sensor, IR optical sensor, ultrasonic sensor, Bluetooth module, WiFi module are connected to the Arduino Uno microcontroller board according to the circuit diagram.

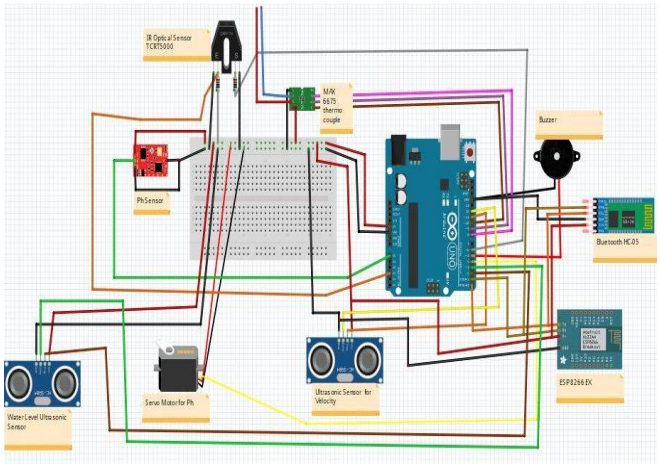

Fig. 2. The circuit design of the proposed system

The proposed model is designed with the following components:

B. Hardware: Following pieces of equipment are utilized to develop the hardware part.

1) Arduino Uno: ATmega328 IC based Arduino Uno has six analog inputs, 14 digital i/o pins, USB connection, 16MHz oscillator, ICSP header, reset button, power jack and 6 PWM output pins[17]. The physical computing platform of the Arduino Uno board is an open source.

*2) pH Sensor:*pH sensor measures the alkalinity or acidity of a solution that's scale range is from 0 to 14 where 7 is considered as neutral, below 7 acidic, above 7 alkalic.TOL-00163 model of pH sensor is equipped to measure the pH level of the fisheries water[18].

3) HC-SR04 Ultrasonic Sensors: Ultrasonic wave based, HC-SR04 ultrasonic sensor's head emits an ultrasonic wave and receives the reflected wave from the target. Measuring the taken time between the emission and reception it measures the distance to the target. In this system, HCSR04 ultrasonic sensors are used to measure water level and fish movement for detecting hungry level. At 40 KHz frequency, it can identify an object at range from 2cm to 400 cm[19].

4) IR Optical Sensor: The TCRT5000 IR optical sensor is a reflective sensor which incorporates an infrared emitter and phototransistor in a leaded package that prevents visible light[20].

5) Bluetooth Module: Among various types of Bluetooth module HC-05 Bluetooth module is selected for the system that works on 3.6V to 6V. 9600 is its default baud rate [21].

6) Wifi Module: TCP/IP protocol based ESP8266 Wi-Fi Module has a powerful enough processing capability that allows it to be integrated with the sensors with

minimal loading during runtime. In this system, it is used to transfer real-time data at the server side[22].

C. Softwares:

Arduino IDE and language is used to write the code and burnt into the system that is easy to understand and reliable.

D. Algorithm:

The algorithm is described by a flow chart. The whole flowchart of an IoT based ideal fishery system appears in figure 3.At the first level, all sensor values are initialized. To measure the pH value, servo motor rotates 30 degrees left, and 30 degrees right as pH sensor needs to shake for proper value. By using pH formula, pH is determined 5times in every 3min. Average of the pH value is calculated for a 15min duration. As optimal pH value for speedy growth of fishes is 7 – 8.5, the system turns on the alarm if it exceeds this range[23]. IR optical sensor engages to measure the oil layer of the water. The output of the IR optical sensor gives a wholevalue, heat and noise value. By removing the heat and noise value form the entire value, the system gets the actual value.

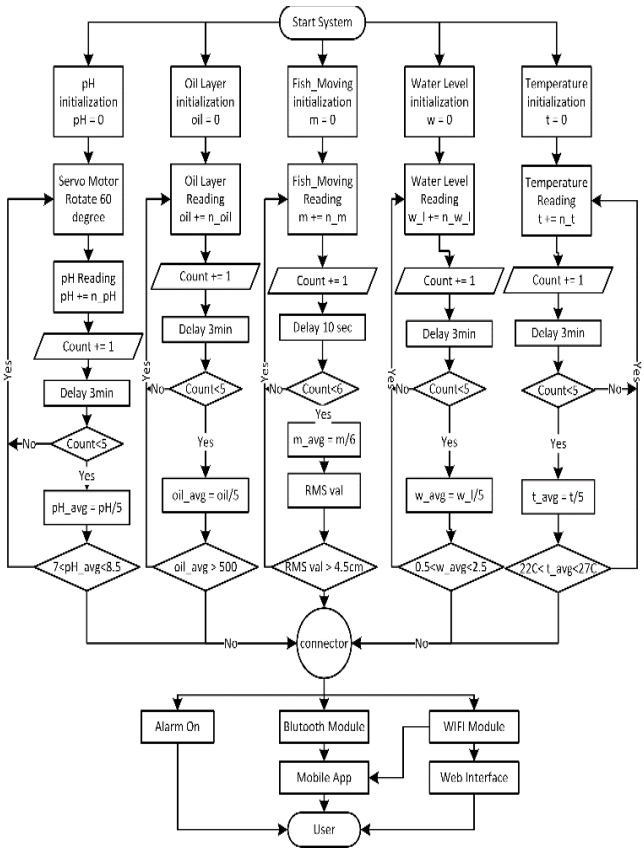

Fig. 3. Working process of the proposed system

Like the pH sensor, the average value of this sensor is measured in the same fashion. If the oil layer value less than 500 than it notifies the user and turns on the alarm. To estimate the fish moving rate, every 10 sec is taken in 1min duration. 4.5cm Root Mean Square (RMS) value of the sensor act as a threshold value to determine the hungry level of the fishes. Average value of the water level and temperature within 15min is calculated like the pH sensor.[24]says that 22C to 27C is the optimum temperature for the rapid growth of the fish. So, in case of exceeding this range, the system informs the owner of the fishery through mobile app and web interface. The flow of the data from the device to the mobile app and web is performed through the Bluetooth and WIFI module.

E. Predicting the following day power consumption:

The system can forecast the various essential parameters and notify the user. For simplicity here we have considered just forecasting of the probably required fish feed in next day. Like this process, the system can predict other parameters. To select the best regression model for our forecasting feature, different kinds of machine learning regression algorithm have experimented. From a local fishery, their daily fish feed supplied amount is recorded for the purpose of making a data set. We have recorded about 200-day data of that fisheries and used the data to train our model. Dataset is split into 70% and 30% where 70% data is for training and 30% data is reserved for testing the model. Through different kinds of machine learning regression algorithms such as linear regression, decision tree regression, polynomial regression, support vector regression (SVR) and random forest regression, we fit the training data to prepare the model to forecast the amount of the fish feed in the following day. After finishing the model training part with training data, the model is examined by testing data. Then Mean absolute error and accuracy level is calculated to evaluate the model. From these results, we have found Random Forest Regression gives better outcomes than other regression models.

IV. Experimental Results and Discussion

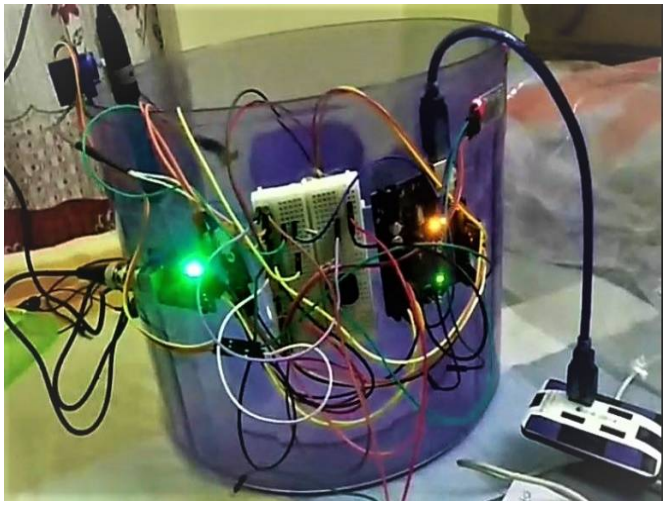

Fig. 4. Photograph of the prototype

A prototype of the proposed system appears in figure 4. pH, temperature, oil layer, water level, the hungry level of the fish

are the outcomes of the system. The essential parameters of the water are sent to the mobile app through Bluetooth module for local user and data sent to the web server through the ESP8266 WIFI module for the remote user. Also, data is saved to the cloud storage for further analytics. In case of any parameters exceeding the predefined threshold value, the system notifies the local user as well as the remote user.

In figure 5 we have seen some sample outcomes of the system taken at different time and different situation. In figure 5(a) we have seen all parameter is ok while at the time of medium hungry level the system notifies it successfully (figure 5(b)) and inform the user. In case of pH level decreasing the system notify the user, shown in figure 5(c) while in the oil layer exceeding the threshold value case the system successfully determine the situation.

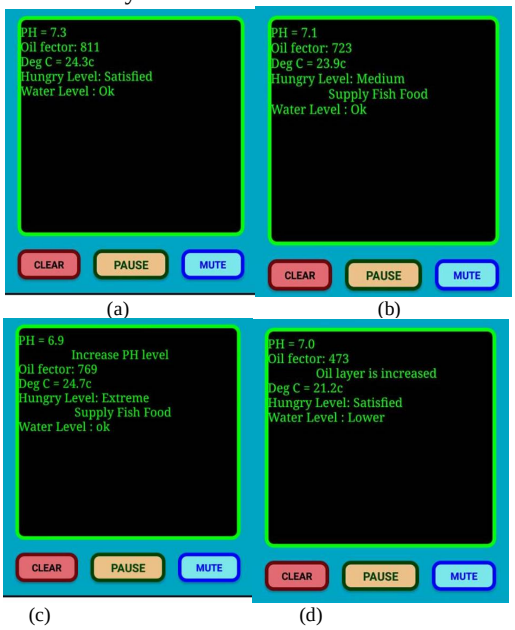

Fig. 5. (a) A sample of everything ok, (b) A sample of fish hungry notification (c)A sample of Ph and hungry level notification, (d) A sample of oil layer notification

In the web interface, the system sent the measured data and visualized it graphically to make it more interactive with the user. In figure 6, the system visualizes the pH data over time and store it into the server for further analytics. Like the pH data visualization, the system also visualizes the temperature data (figure 7), oil layer data (figure 8) and water level data (figure 9) graphically into the web interface for the remote user.

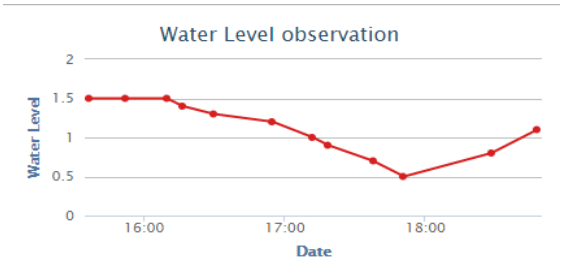

Fig. 9. Water Level observation

TABLE I. TESTING DATA

Date Test	Fish Feed (g)	Linear Regression	Polynomial Regression	Support Vector Regression (SVR)	Decision Tree Regression	Random Forest Regression
113	10096.59	10101.15	10101.31	10294.05	10602.16	10524.65
218	10173.3	10176.01	10178.49	10294.79	10693.29	10418.38
303	10235.84	10236.61	10237.68	10294.44	10732.53	10593.94
515	10394.56	10387.76	10383.78	10295.23	10561.82	10582.49
717	10572.98	10531.77	10539.52	10295.58	10732.19	10689.75

To forecast the following day power consumption, our trained model is examined by testing data. Some forecasted data are displayed in table 1 where the 1st column “Date Test” refers to the forecast of the power consumption of that date. “MonthDate" format is used to represent a date where the last two digits refer to data and remainder value to month. For example, "218" implies 2nd-month 18th day, “717” implies 7th-month 17th day and so forth.

Accuracy level and mean absolute error is considered to judge the model that is shown in table 2 and table 3

respectively. Because of varying the parameters, the outcomes diverge from one regression analysis to another regression analysis. For example, shifting the degree of polynomial regression analysis provides a good result than linear regression. Random forest regression gives a better result than decision tree regression and other models. So, it can be decided that the random forest regression-based model is more suitable to forecast the water parameters.

TABLE II. ACCURACY COMPARISON

Accuracy	Linear Regression	Polynomial Regression	Support Vector Regression (SVR)	Decision Tree Regression	Random Forest Regression
Training Set	85.45	85.49	87.49	92.09	95.75
Testing Set	84.76	84.85	86.05	90.94	94.24

TABLE III. MODEL EVALUATION

Evolution of the Linear Model		Linear Regression	Polynomial Regression	Support Vector Regression (SVR)	Decision Tree Regression	Random Forest Regression
Mean Absolute Error	Training Set	44.2489	44.2063	29.2189	26.3687	23.0747
	Testing Set	43.6042	43.2575	35.5301	30.2692	23.8518

V. CONCLUSION

In demand for the increased level of protein for the fast-growing population of the world, the fish production needs to be raised. Traditional fish cultivation method is failed to meet the demand because of the adverse environment and ignoring the current behavior of the fish. This study proposes an IoT based smart fish monitoring and controlling system where various essential water parameters and fish behavior is continuously measured and notify the local user as well as the remote user in case of any abnormal situation arisen like increased pH or dense oil layer etc. To make the system more user-friendly, a web interface and mobile app are created so that the user can examine all earlier data from everywhere in the world. Alongside these characteristics, the system can forecast the water parameters like pH, oil level, water level, temperature, the fish feed of the following day by machine learning regression algorithm that will assist them to take an advanced step in the fish farm. The proposed framework is more cost-efficient and smarter than existing tradition system as well as other smart systems. Reducing the cost of the system and integrating other important feature like determining the poison in the water is a future scope of the present system. The fish farmer should integrate our efficient and effective system to increase their fish production and defeat the challenge of the protein problem.

***Abstract*—**
Internet of Things (IoT) is receiving more and more attention in recent years. Even though a great number of researches have been going on focusing the field IoT, research on Digital Forensics Investigation (DFI) techniques are still little focused. Till now IoT platforms have not fully matured to adapt with the existing Digital Forensic(DF) tools, methods, and procedures. The prime reason is the nature of the cloud, network and IoT infrastructures (e.g. heterogeneity, distributed, jurisdiction, data duplication, multi-tenancy etc.). As a result, it is a very challenging task of locating, identifying, examining, analyzing, and presenting the potential IoT-based forensic evidence for digital forensic from the device, Network and, cloud environment. Consequently, there is no fully adapted international standard for an ideal framework to conduct DFIs. Because of this, we are proposing a comprehensive DFI process framework for the IoT environment that is able to enable more efficient and effective for DFI. The aim of this paper is to present a more comprehensible DFI framework for digital forensic professionals and experts. Also, it would be a proper guideline to guide the investigators and would also be useful in training of the fledgling investigators. Moreover, it reduces the dependence on the Cloud Service Provider (CSP) at the time investigation is going on.

***Keywords*—IoT, Digital Forensics, DFI, Forensics, Cloud Computing, CSP, ISP, Cloud forensics, Network Forensics etc.**

I. Introduction

IoT [1] is an infrastructure where smart nodes are connected to each other in a progressive and worldwide network infrastructure. Every day thousands of devices are being connected with the internet and sharing the local information. IoT can be applied in different areas like the smart city, smart home, transportation, farming, health care, etc. According to the information by Gartner, there will be an estimated 20.4 billion IoT devices be connected by 2020 (things). In accordance with the vast growth of IoT devices- that faces some new challenges in terms of security, it is becoming a new battlefield for cybercrime. Since billions of IoT devices are connected to each other and sharing their information from the device to device through various distributed network and cloud environment. Sensitive data communication from a complex system may encounter security threats as the data travel through various communication routes and devices. Various researchers have shown that threats, attacks, and different security issues on the IoT platforms that have been identified include: Virus & Worms, Spyware & Malware, Distributed Denial of Service (DDoS) etc [2]. These types of attacks may lead to power systems failure, failed user devices and, even sometimes infrastructure failures. As a result, it is always at risk of intruders, who may find out the weakness of crucial IoT infrastructure related to health, safety and communication systems and introduce malicious data to the systems. Investigation of these kinds of threats needs sophisticated DFI methods into the IoT domain. We call this new paradigm *IoT Forensics*.

In present years, numerous attacks on various social networks like Google, Yahoo, Facebook, Twitter etc are observed. Most of the social networks are affected by the Distributed Denial of Service (DDoS) attack. Moreover, capturing confidential information of users by phishing attacks, like doing illegal transactions by obtaining personal security information.

Furthermore, cloud computing is another part of networking that has limitless storage and processing capacity. With the sporadic growth of global cloud adoption in private, public and hybrid sectors, cloud computing environments face some new challenges every now and then in terms of security through increased crime-ware. In cloud computing, sensitive data communication from such complex virtual systems may often become vulnerable. Sometimes attackers find out the vulnerability or weak-point to trigger malicious data. Investigation of these kinds of attacks requires DFI methods into the cloud computing domain. This is also known as the *Cloud Forensics*.

Contributions: The contribution of this paper are as follows:

- We are proposing a comprehensive IoT-Based forensics framework, to reduce the dependence on the CSP and the network logs at the time investigation is going on.
- We are systematically analyzing and explaining the opportunities for IoT-Based forensics. We are designing this model to help researchers while focusing on very specific research sub-problems within the Cloud, Network and, Device forensics problem domain d for being a proper guideline to guide investigators and to be useful in training the fledgling investigators.

Organization: The organization of this article is as follows: We are describing related works in Section 2. Background knowledge on digital forensics and digital forensics models regarding the digital forensic investigation process models are discussed in Section 3. After that, we are proposing a comprehensive a DFI Framework for IoT and we are discussing how the proposed framework can work in section IV. Finally, we are concluding the paper in Section V.

II. Related Works

Significant research efforts have been observed in recent years on cloud and IoT forensics. In this section, we are presenting some related works: A recent study [3] has proposed a DFI Framework for IoT (DFIF-IoT). This framework is focused to support forensics investigative capabilities related to IoT in the future. The special features related to the framework is, it complies with the ISO/IEC 27043 standard: 2015.

Another paper [4] has suggested that application-aware forensic methods are needed to be implemented for specific IoT applications to ensure that data evidence remains within the context of the application. The study has considered three IoT applications (Wearable, Smart home & Smart city) and has proposed a forensic process which is application specific.

In another study [5] the researchers have tried to reduce the dependence on the Cloud Service Provider (CSP). The authors of the study have suggested a model for the collection of evidence by remaining outside of the cloud environment. The study has tried to mitigate the problem of over-dependence on CSP by suggesting a pre-implemented forensic server for evidence collection.

A survey work [6] has presented a study from the opinions of experts and practitioners related to digital forensics. This study has explored the important issues that are vital for cloud forensics like the definition, challenges, and opportunities.

Another similar study [7] has explored the critical challenges, recent proposals and technical solutions from the literature, related to cloud forensics.

A study [8] has tried to explores the issues related to cloud computing such as the role of CSP and it has also proposed a model named Open Cloud Forensics (OCF) model. The researchers also tried to validate the model using a civil lawsuit based case study.

Another similar work [9] has also explored the challenges and their probable solutions related to cloud forensics. This paper has also proposed a framework for cloud forensics and has also proposed a method for the collection of evidence from the Eucalyptus Cloud.

III. Background

In this part, the following topics will be covered: Digital Forensics, Digital Forensic (DF) models.

A. Digital Forensics

Various types of DFI techniques are required to breach the computing system for seizing the digital evidence to find out who has performed the digital attack, what malicious attacks have occurred, possible degree of risk and the potential outcomes after security assessing. The National Institute of Standards and Technology (NIST) defines digital forensics as an applied science to identify an incident, collection, examination, and analysis of evidence data. Based on the premise, digital forensics includes four processes:

- **Identification:** Identification of an incident and identification of the potential evidence.
- **Collection:** After identification of incident and evidence, the investigator tries to extract the IoT crime-related evidence from numerous physical & logical devices, cloud environment, network devices, and etc.
- **Organization:** Organization are closely related to two stages: Examination and analysis In the first stage, after extracting the IoT related information from the crime scenes investigator examines the evidence and observes its characteristics. In the second stage, all investigators analysis the evidence and try to establish a co-relation the receivable evidence for judgment.
- **Presentation:** In this process, evidence should be documented to store the chain of custody. An investigator generates a detail report with an explanation of presenting into the court for proof.

B. Digital Forensic Models

Since the first DF Research workshop [10], digital forensics models are being proposed on a regular interval but none of them are adopted fully. One of the models is- Digital Forensic Investigation Process (DFIP) model -presented by Valjarevic & Venter [11]. This model made an effort to incorporates the existing models. Other mentionable models include: Event-Based Digital Forensic Investigation Forensic Framework [12], Hierarchical, objective-based framework for digital investigation processes [13], Integrated Digital Forensic Process (IDFP) model [14], Generic Digital Forensic Investigation Framework for the Internet of Things(IoT) [3], Top-Down Forensic Approach Methodology [15] and Application-Specific Digital Forensics Investigative Model in an Internet of Things (IoT) [4]. Still, there are no models or standards that are accepted globally to collaborate with IoT.

IV. Proposed Framework for IoT-Based Forensics

In this section, Fig. 1 is introducing a DFI Framework for IoT. The proposed framework includes Readiness process, IoT forensics, Initialization process, Acquisition process, Investigation process, and Concurrent process.

A. Readiness Processes

The readiness process is also called iterative process. Readiness Processes including the following sub-processes:

- **IoT Scenario Definition:** In this step, all possible IoT scenarios should be examined to gather potential digital evidence with a proper risk assessment.
- **Identification of Potential IoT Evidence Sources:** In this step, all potential evidence sources like smart home,

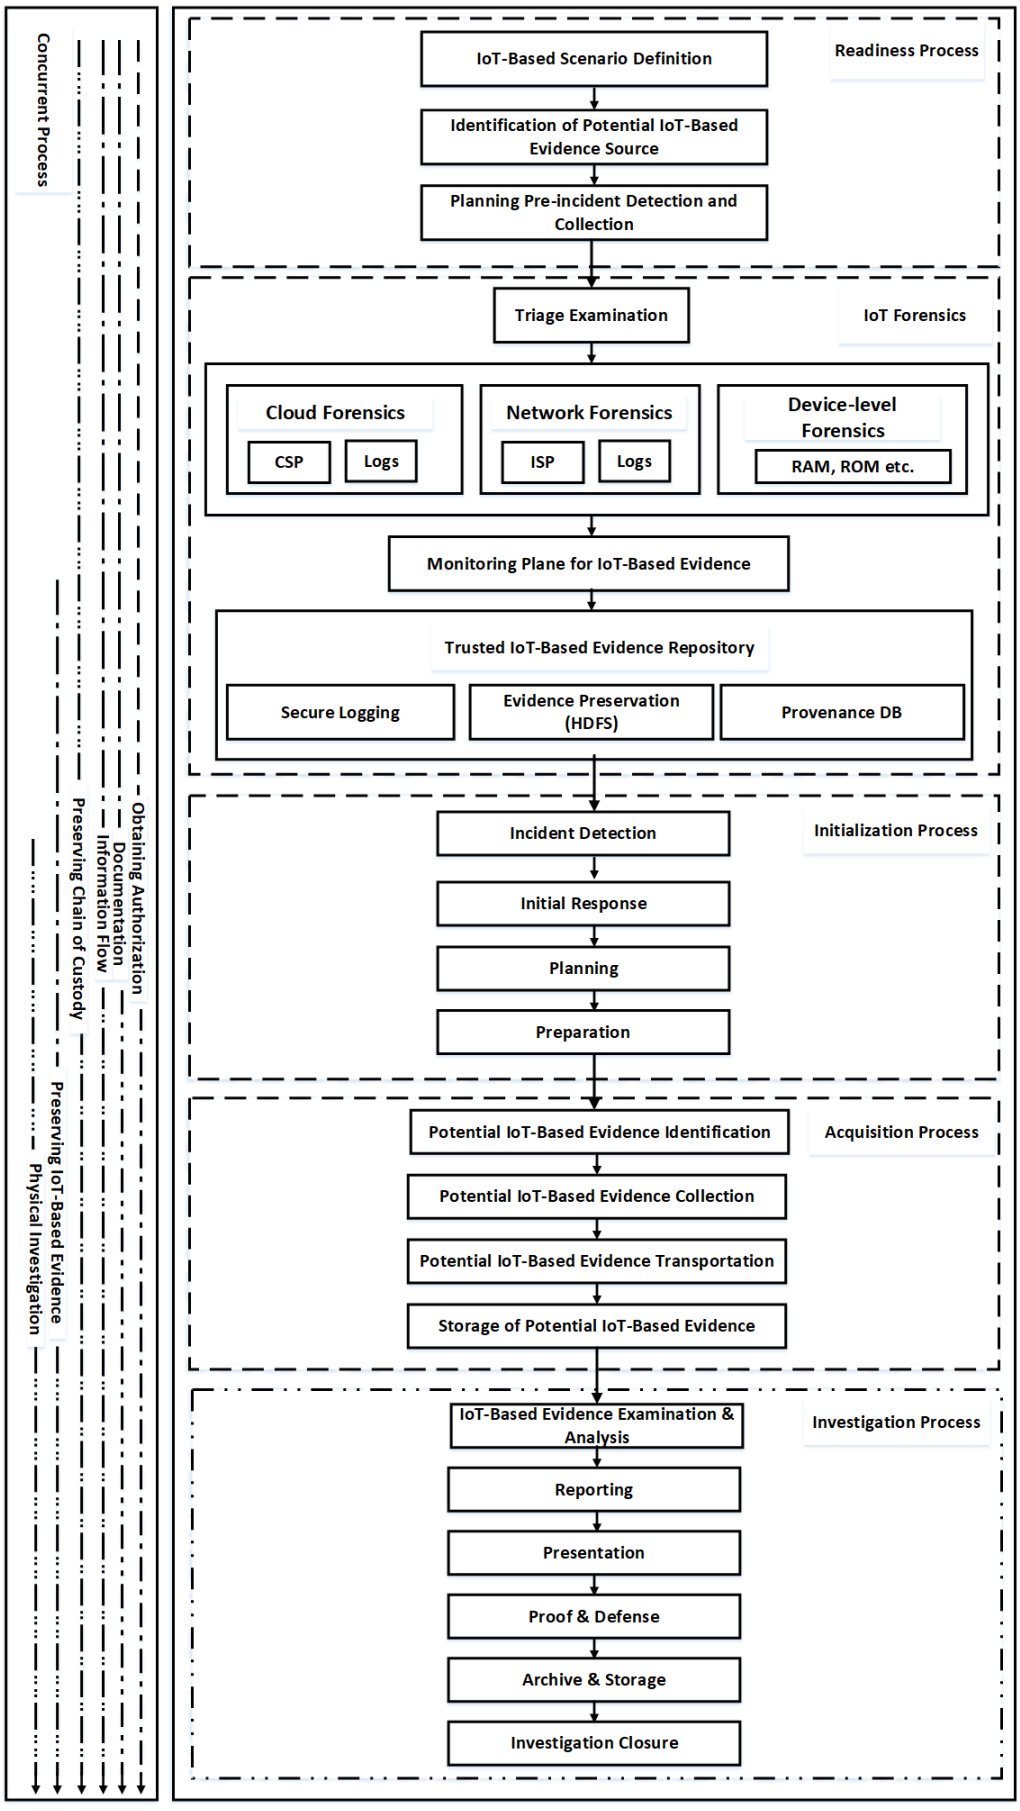

Fig. 1. Proposed Framework for IoT-Based Forensics

smart cities, health devices, cloud services, smart grid etc. are identified.

- **Planning Pre-incident Detection and Collection:** In this step, all activities for IoT-based pre-incident detection, storage and handling of IoT data should be defined.

B. IoT Forensics

IoT forensic is a special branch for DFI, where the identification, acquisition, organization, investigation, and presentation establishes an attacked incident with detail. There present numerous types of IoT forensic schemes, e.g. cloud forensic, Network forensic, device forensic etc.

1) Cloud Forensics: Data extraction and analysis is very difficult from the cloud environment because of lacking in data integrity, the huge amount of data, data diversity, multi-tenancy, jurisdiction, data duplication, and the high degree of virtualization. Previously, There is various type of solutions have been implemented and proposed for cloud forensics. But no one has considered about the CloudIOT forensic. However, For collecting the IoT forensics evidence, investigators fully dependent on the CSP or Cloud logs [5]. Cloud Logs are collected and stored the forensic evidence for investigators. So, most of the investigators and users are dependent on the CSPs server logs or network logs. To overcome this limitation, we are considering a Forensic Monitoring Plane (FMP) for data collection issues shown in Fig. 1. Data from the cloud will be stored in the proposed IoT-Based evidence repository through the FMP [5] [8]. The investigators are needed to analyze the evidence from the data repository. For that reason different types of cloud computing forensic tools will be needed such as Forensic ToolKit (FTK), E-detection, Encase, Recover, Recuva, Blade, etc. [16] running on the repository outside the cloud computing environment. After that, forensic evidence is forensically imaged bit by bitstream encryption and stored the data in the forensic server. Because we need to create the image of the original forensic evidence without any damage. These tools automatically capture the evidence from the current state of the cloud and stored the forensic evidence on the cloud server or trusted repository.

2) Network Forensics: This represents the IoT environments which incorporate different networks such as industrial network, home network, LANs, MANs, and WANs. Attack logs can be gathered from all these networks to be used with the DFI process.

But, data extraction and analysis are very difficult from the distributed network environment because of lacking in data integrity, the large volume of data, data diversity, data duplication, high-speed data transmission, data extraction location, data storage on the network devices, data privacy, access to IP addresses and, etc. So, most of the investigators and users are dependent on the ISPs server logs or network logs. To overcome this limitation, we are considering data collection issues presenting a Forensic Monitoring Plane (FMP) outside from the network environment infrastructure shown in Figure 1. Data from the network environment will be stored in the proposed IoT-Based evidence repository through the FMP [5] [8]. The investigators are needed to analyze the evidence from the data repository. For that reason, different types of network forensic tools will be needed such as network analysis tools, vulnerability assessment tools, network sniffing and packet analyzing tools, network scanning tools, and Network monitoring tools [17] running on the repository outside the environment.

3) Device-level Forensics: IoT-based evidence can be collected from physical devices like memory (RAM, ROM, or various secondary device), graphics, audio, video, image, files, and other IoT devices. But, data extraction and analysis are very difficult from the device environment because of lacking in data integrity, data diversity, data duplication, data extraction location, data privacy and, etc.

When a crime has occurred in a cloud, network, and device-level scenarios, an investigator can directly access (with secure logging) in the trusted evidence repository with user credentials and collect the pieces of evidence. Various types of Forensic tools are conducting in the cloud, network and, device-level when an attack occurs in the environment and finally, it collects the forensic images from the environment and stores in the evidence repository. In this paper, We are considering a secure evidence preservation module for evidence storage, as shown in Fig. 1. While evidence is stored on the module, it separates the evidence based on the IoT-based devices and its owner. In that way, we can separate the multiple user's data. This module stores the evidence by using public-private key based encryption (RSA, AES) [18] so that only investigator can access this module with secure logging and can examine or analyze the evidence. But it is difficult to manage very large data-sets. Hence, we are proposing a Hadoop Distributed File System (HDFS) [8] as the trusted IoT-based evidence repository, as shown in Fig. 1. This is Google's proprietary Map-Reduce framework, which is designed to solve problems involving big amounts of data sets computationally efficient. For big datasets, HDFS provides better performance than any other conventional repository system. Moreover, any hardware failures in the system will be automatically handled by this framework. We are using another module named Secure Provenance Module (SPM), which is used to store the access history of digital evidence. Finally, we are using the Application Programming Interface (API). An investigator can access (with secure logging) the trusted repository by using these APIs.

C. Initialization Process

Initialization Process(IP) including incident detection, first response, planning and preparation processes [11].

- **Incident Detection:** This is the first procedure of the initialization process. The procedures can define where the incident might occur.
- **Initial Response:** The initial response procedure should be included when the initial response to be detected IoT-based incident. Based on the incident types, that will disconnect the materials from the network environment and will detect the attacked equipment's.

- **Planning:** In this procedure, the investigator plans about the IoT-based Forensics Investigation. Planning should be included about the development of the relevant procedure such as procedure methodology, tools, technology human resource, etc.
- **Preparation:** Preparation activities should be included about the IoT-based forensics investigation. This should be included, but there are no limitations of preparation. IP Preparation including hardware, software, documents, training etc.

D. Acquisitive Process

The acquisitive process is closely related to the physical investigation [11]. It is purposed to uncover Evidence (DE) that are related to IoT. This process insists on the following procedures:

- **Potential IoT Evidence Identification:** This is the first procedure of the acquisitive process, the aim of this procedure is to identify the potential IoT-based evidence. But It is a very difficult and challenging task to identify the IoT pieces of evidence from the incident place in the cloud environment because the cloud environment deals with an exceptionally large amount of data.
- **Potential IoT Evidence Collection:** After identifying the IoT-based evidence from the incident scene, this evidence will be used for analysis in the later procedure. So, anyhow evidence should be collected from the crime scene for analyzing purposes.
- **Potential IoT Evidence Transportation:** During this procedure, after collection of the IoT-based evidence, it should be transferred from one place to another secure place for storing purposes that we can easily analyze next.
- **Storage of Potential IoT Evidence:** This is the last procedure of evidence acquisitive process. For examining and analyzing purposes, the potential evidence is needed to be stored. In this time extra care is needed to avoid the damage of digital devices. IoT evidence can be lost and damaged because of shocked by electricity, dead heat, cold, dirtiness, sudden power loss, function failure, and etc.

E. Investigation process

Investigation process consists of six procedures e.g. IoT Evidence Examination and Analysis, Reporting, Presentation, Proof & Defense, Archive & Storage and Investigation Closure [11]. In the beginning, evidence from the IoT devices is

examined and analyzed. After examining and analyzing the seized evidence, a report is needed to be created for presenting to all stakeholders. The stakeholder includes the judge, jury, accused, lawyers, prosecutors etc. The process is needed to be proofed based on all IoT-based evidence that is collected from an incident scene. Investigation process also checks the validity of the evidence for the investigation process. Deciding on the court, evidence could be accepted or rejected. Investigation closure concludes the investigation. After concluding the evidence documents it is needed to be archived & stored in a secure physical disk.

F. Concurrent Process

The concurrent process has been introduced by Valjarevic & Venter [11]. This process can improve the acceptability of IoT environments without any difficulty. Authorization is involved with the whole process of DFI framework which contains authorities, users, owners information. Moreover, the chain of custody is used to enhance the proficiency which stores the information related to the DFI. It also used to identify the information flow and secured the DFI in IoT-based environment. Furthermore, preserving the evidence of forensics is an important part of DFI. After collecting the evidence you should preserve and check the integrity of original evidence with a secure lock and must ensure the evidence will be unchanged. These process must confirm that the original IoT-based evidence is not altered. Sometimes, evidence needs to be transferred to the third parties. For these reasons, evidence should be stored in a physical device that also ensures the protection of evidence and easily handed to the trusted person. The whole concurrent process is used to conduct the DFI process properly with secure integration with IoT environment.

V. CONCLUSION

Even though IoT environments are immature; the standards of security and service are still evolving. Day by day, various research challenges have been arising on IoT forensic and some researchers are trying to solve the difficulties. However, The difficulties and problems that this paper has addressed previously are stated as follows: there is no global or international DFI method or framework which can facilitate the IoT environment. Based on the above analysis, we are introducing a comprehensive DFI process framework for the IoT environment that is able to enable more efficient and effective for DFI. The primary aim of our research is to conduct useful DFI for investigators and experts. In this paper, we are systematically analyzing and explaining the opportunities and try to solve some of the problems for IoT forensics but solving all the challenges are still very difficult. So, there are many aspects that need improvement. Moreover, the proposed framework reduces the dependency on CSP or cloud logs for acquiring evidence from the cloud. Moreover also reduces the dependency on ISP or network logs for acquiring evidence from the network. In the future, the proposed framework should also be included in more procedures and techniques for DFI.

***Abstract* – Internet of Things (IoT) is the network of the huge number of resource-personated nodes whose main feature is the reliable communication and fast data exchange among devices in any network topology. In the upcoming world of internet, proper selection of desire or appropriate destination node and finding the optimized path from the huge number of the activated nodes is a very important task. Here many nodes are available in one or more hop distance and each node has various network parameters in the IoT world, so the selection of best path and nodes is quite complex. For this reason, we need to develop an algorithm to find out the best path towards the destination node considering significant network parameters. This paper proposes a general algorithm considering any network topology for discovering the path towards the destination node from the source node and give a solution to the contradiction which may arise if there is more than one consonant path. The proposed algorithm considers the node property of all node for calculating the behavior value, path influence behavior value and finally discover the optimized path from source node to destination node. The proposed algorithm is also evaluated by simulation to determine the impact of parameters in path determination.**

Key words- Node, Path and Partner selection, Path Influence Behavior, Node Parameter, IoT.

I. INTRODUCTION

In a cooperative service scenario like IoT, where many nodes are present in the IoT field, the most appropriate node selection can be a complex task for transmission of data [1]. Nowadays, IoT is the rising technology in scenarios such as smart city, smart home, eHealth, service, etc. Information is generally carried over by lossy networks and low power consists of smart nodes, many of those have limited power capacity and processing capability, and over very dynamic IP-based connections [1]. IoT operation depends on the identification, automatic management and use of a huge number of diverse physical and virtual objects (i.e. both physical and virtual representation), connected to the Internet [2], [3]. Additionally, the identification of a particular object and its addressing scheme ability to dynamically configure their addresses is also an open issue [4].

Because of many available nodes in network topology, proper selection of nodes and path is an important decision for data exchange between nodes to nodes. Therefore, the behavior of nodes may be changed after a certain time period. Also, the influence behavior of nodes may differ depends on specific communication service requirements. In IoT research field, the behavior of path and node selection is still in the initial stage. If a node wants to start communication, there may be a destination node is defined or not. Another case is that destination partner can be far away one or more than one hop distance. Some research work has been done on node discovery, node interpretation, and established the connections among available nodes in the world of IoT [5], [6].

A representation for the discovery and selection of a node in large-scale, resource-constrained environments in the context of service and application requirements was proposed and assessed [5], [6]. This representation relies on a fundamental mathematical approach which describes and predicts the positive outcome of human interactions and communications in terms of long-term relationships and recognizes various key variables in resource-constrained environments [5], [6]. The methodology is used to develop this model adopted from [7]. The mathematical model of the network parameters, such as Device Class, Influence function and Influence behavior are shown in [5], [6]. Three network architectures are proposed for

data storage and reliable communication in the context of IoT [5]. An algorithm named "choosing a partner" is proposed in [6] and extended in [5]. An algorithm named "the behavior of a whole path" is proposed in [5], but there are some limitations. Also, a new priority of node called Emergency Priority and a new parameter called Reliability & service type properties proposed and performed simulations on behavior parameters and convergence of the behavior value [5].

The following paper proposes an algorithm for node selection and path evaluation based on path influence behavior, behavior value, node parameters, which is applicable for any kind of network topology either destination node is one hop or more hop distance and help us to find the optimized path. There was no such algorithm for path and partner selection in [5], [6].

The rest of the paper organized as follows: Section II addresses the related works. Proposed Methodology is represented in Section III. Section IV describes our experimental evaluation, Section V provides the conclusion of the proposed paper and Section VI suggests some future work over the algorithm.

II. BACKGROUND

A.Node Parameters:

Here we consider some IoT node parameters which help us to evaluate the fastest and best path to communicate among nodes [5] [6]. The Node parameters are shortly described here:

Device Class: Device Class is a number which indicates the potentiality of the node. It is composed of resource parameters (device speed, processing power, data storage, battery life, digression from the power efficiency defined by the throughput, manufacturer). The range of Device Class is [4; 20] where 4 means low power device and 20 means high power device.

Free Resources: Free resources is another node parameter which discloses the actual free resources present in that node. The range of free resources is [0; 0.9] where 0 means 100% of the resources are occupied and 0.9 means 100% of the resources are free.

Reliability Score: Before any communication, the source node needs to know how reliable the candidate nodes. The *Reliability* is another IoT node parameter which gives information that how reliable a node is. For IoT node, we use reliability instead of security. The range of Reliability parameter is between [1; 10] where 1 means least reliable and 10 means most reliable.

Influence Function: Another most important node parameter is Influence function. It is a function of Influence Behavior which indicates the influence of one node has on its partner. It is also used in the evaluation process of communication is described in [5], [6] with its score and description.

B. Modelling Node Interaction:

In [5] [6], the authors introduced a mathematical model which is used to define the *Influenced Behavior* scores. It is a score showing the strength of a node depending on its available resources and the demands it has to meet. The relationship equation of this mathematical model is given below:

$$N_{1(t+1)} = I_{N_2 N_1}(N_2)t + r_1 N_{1\,t} + a \quad (1)$$

$$N_{2(t+1)} = I_{N_1 N_2}(N_1)t + r_2 N_{2\,t} + b \quad (2)$$

Where N_1 is the Influence behavior of Node 1 and N_2 is the behavior score of Node 2. The details of the above equations are described in [5], [6]. Behavior has an only positive value and this value is used in connection establishment among nodes.

C. Algorithm for choosing a partner:

An algorithm for choosing a new partner in IoT topology was proposed in [6] which was extended in [5] including Reliability parameter. When a node wants to communicate with another node away from one hop distance and there is no fixed destination node, this algorithm is used to find out the appropriate partner node from the available nodes. At first, the source node calculates its uninfluenced behavior score and then sends the application requirements to its all neighbor nodes in one hop interval. The neighbor nodes receive the requirements and send back their own Device Class and influence behavior score to the source node. Then the source nodes choose the best partner node considering the Behavior value, Device Class and Reliability score.

D. The Behavior of a whole path:

A procedure for establishing an entire path and calculate behavior score named "Behavior of a Whole Path" was described in [5]. By this mechanism, we can calculate the Behavior value of the node to node communication and used it in the further calculation. For a specific proposed scenario, source node broadcast its requirements towards all its neighbors. Neighbor nodes of the source node modified the requirements and broadcast to their neighbors and so on. When the destination node receives the requirements it calculates its own behavior value and sends this value towards the node of the previous path. Then, a node of the downstream path calculates the path influence behavior.

The weak points of this algorithm are:

- This mechanism is only applicable to the proposed scenario shown in [5]
- There is no exact algorithm without only a scenario model.
- If there is more than one candidate path, this algorithm can't give any solution.

III. PROPOSED METHODOLOGY

A. SYSTEM ARCHITECTURE:

The proposed methodology is applicable for any kind of network topology. Here, we consider the following network topology, for example,

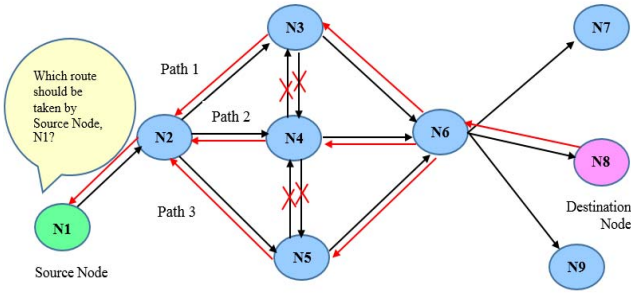

Figure: Sample Network Topology

Fig. 1: A network topology contains 9 nodes

In the scenario, Source node N_1 wants to find a reliable path towards Destination node N_8.

There are three possible paths -

1. $N_1 \rightarrow N_2 \rightarrow N_3 \rightarrow N_6 \rightarrow N_8$
2. $N_1 \rightarrow N_2 \rightarrow N_4 \rightarrow N_6 \rightarrow N_8$
3. $N_1 \rightarrow N_2 \rightarrow N_5 \rightarrow N_6 \rightarrow N_8$

We propose the following algorithm to choose an optimal path by the Source node to communicate with the Destination node for exchanging the data.

B. PROPOSED ALGORITHM:

The proposed algorithm Path and Partner Selection in Unstructured Resource-Constrained Environments Based on Node Psychology in the Context of IoT is applicable for any kind of network topology. This algorithm is applicable for one hop or more hop distance and also can give an exact solution if there is more than one candidate path.

The steps of the algorithm are as follows:

1. Appended the network parameters with the nodes present in Network Topology.

2. Define the Source node (N_s) and the Destination node (N_D) among all the nodes.

3. Setup Quality of service (QoS) requirements for the Source node. Quality of service means application requirements which are essential for any application. Suppose, for a certain application, source node needs Delay 500ms, Throughput 1.5Gbps.

4. Source Node (N_s) wants to find a path to the Destination node (N_D) (n hop distance).

5. N_S sends a package including its application requirements, the name of destination node as header to its neighbors.

6. Neighbor nodes modify requirements and forward packets to their neighbors and continue.

7. N_D receives requirements and identifies itself as a final destination, calculates its influenced behavior based on the modified requirements and replies the packets along with the previous path.

8. Every node in the path calculates the path influence behavior, an average of its influence behavior and the influence behavior of the previous neighbor node.

9. N_D receives feedback.

10. It checks whether there is one path having the highest Influenced Behavior or not:
a. If Yes, a path is found;
The source node can communicate with the destination node through this path.
b. If No, continue to Step 11;

11. The node analyzes whether the nodes with an equal highest value of the Influenced Behaviors are from the same Device Class or not:
a. If Yes, continue to Step 13;
b. If No, continue to Step 12;

12. The capable partners with the highest scores for the Influenced Behaviors and with the highest value for the Device Class among all potential partners are saved. Continue to Step 10;

13. Choose the potential partner(s) with the highest value of the Reliability score
14. The node checks whether there is only one potential partner left or not:
a. If Yes, a partner is found;
b. If No, a partner is picked randomly from the remaining pool of partners.

C. REQUIRED EQUATIONS:

Influence Behavior Score:

$$N_{1(t+1)} = I_{N2\to N1}(N_{2t}) + r_1 N_{1t} + a \quad (3)$$

$$N_{2(t+1)} = I_{N1\to N2}(N_{1t}) + r_2 N_{2t} + b \quad (4)$$

Uninfluenced Behavior:

$$B_{UB} = \frac{Device\ Class}{1 - Free\ Resources} \quad (5)$$

Influence Function:

$$I = \alpha I_L + \beta I_D + \gamma I_{PE} + \delta I_S + \varepsilon I_T + \zeta I_R + \eta I_{PDR} + \theta I_{BS} + \iota I_J + \kappa I_{CP} + \lambda I_{EP} + \mu I_{IC} + \nu I_{DC} \quad (6)$$

Path Influence behaviour:

$$PIB = \frac{I_{Current\ Node} + I_{Adjacent\ Node}}{2} \quad (7)$$

IV. Experimental Evaluation

A. Sample Input:

The network topology contains 8 nodes. N_1 is the source node and N_8 is the destination node. The node parameter (Device Class, Free resources, Reliability score and Influence behavior) are given for all 8 nodes. The Quality of Service (Delay time, Latency, Throughput, packet delivery ratio, etc.) are attached to the source node. It is not obvious that all quality of services is required for any communication. Only the interested parameters are set up for distinct communication. The requirements for any service is delivered from source node towards all the nodes in the network topology. The proposed algorithm is applied to the network topology [Fig. 1] and we will get the best path for communication.

B. Numerical Example:

Influence Function,

$$= \alpha I_L + \beta I_D + \gamma I_{PE} + \delta I_S + \varepsilon I_T + \zeta I_R + \eta I_{PDR} + \theta I_{BS} + \iota I_J + \kappa I_C + \mu I_{IC} + \nu I_{DC}$$

```
Node 8 IB : 60
Node 6 PIB : 40
Node 3 PIB : 65
Node 2 PIB : 44.5
Path THREE Selected : Final Influence Factor : 44.5
```

C. Sample Output:

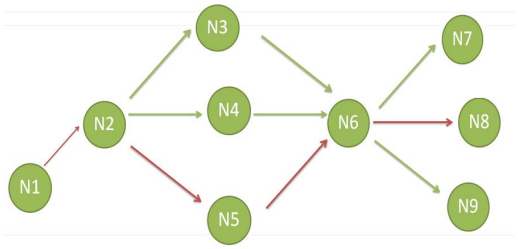

Fig. 2: Simulation output of sample network topology

D. Accuracy Measure

The accuracy of the system can be observed from the theoretical and experimental result. We have tested seven samples for all the network parameters range. The performances of the proposed system are listed here-

Subscript a, b, c, d, e, f for node number n= 4, 5, 6, 7, 8, 9 respectively.

Average accuracy, A_{averge} =∑Ai

$$= \frac{A_{a1} + A_{a2} + A_{b1} + A_{b2} + A_{c1} + A_{c2} + A_{d1} + A_{d2} + A_{e1} + A_{e2} + A_{e3} + A_{e4} + A_{f2}}{14}$$

$$= \frac{100 + 99.99 + 99.99 + 100 + 99.99 + 100 + 99.99 + 100 + 100 + 100 + 99.99 + 100 + 100 + 99.98}{14}$$

$$= 99.995\%$$

We can see that, the accuracy of the performance doesn't depend on the number of nodes. But if the number of node in a path increase the value of path influence behavior will also increase.

E. Simulation Result

a. Relationship between Device Class and Path Influence Behavior

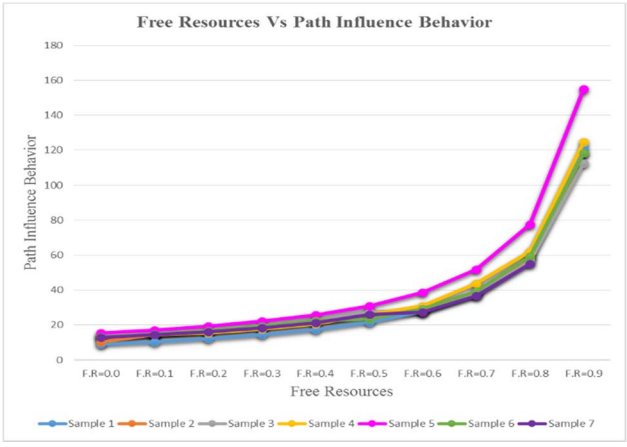

Fig.3: Device Class vs. Path Influence Behavior

In Fig. 3, X-axis shows the Device Class [4; 20], where 4 indicates the less powerful device and 20 indicates the most powerful device and Y-axis shows the Path Influence Behavior.

Observations:

- From Fig. 3, we can see that increasing the value of Device Class will increase the value of path influence behavior which means that powerful device has the highest influence value and prefer for communication among device.
- The lower the value of Device Class, the lower the value of path influence behavior.
- The Path Influence Behavior value doesn't depend on the number of nodes, but depends on the value of Device Class.
- The lower the Device Class, the free resources play a significant role in the value of path influence behaviour.

b. Relationship between Free Resources and Path Influence Behavior:

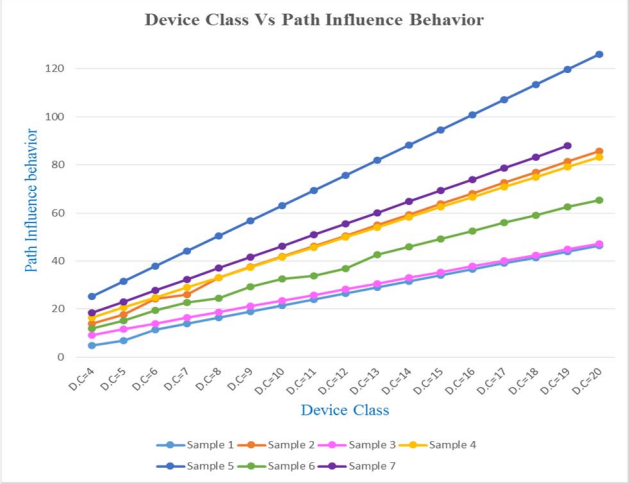

Fig. 4: Free Resources vs. Path Influence Behavior

In Fig. 4, X-axis shows the Free Resources [0.0; 0.9], where 0.0 means 100% resources are occupied and 0.9 means 100% resources are free and Y-axis shows the Path Influence Behavior.

Observation:

- From the figure, we can see that increasing the value of Free Resources will increase the value of path influence behavior that means device contains free resources to get chance first for communication.
- The lower the value of free resources, the lower the value of path influence behavior.
- The Path Influence Behavior value doesn't depend on the number of nodes but depends on the value of free resources.
- Here, we can see an exponential relationship between the Path influence behaviors and free resources.

From the range [0.6; 0.7] of free resources, the value of path influence behavior increases extremely fast.

Based on the figures and simulation result, the following conclusion can be drawn:

- The greater the value of Device Class the greater the possibility for the value of the Behavior to be with higher value. That means that more powerful device can perform well comparing low powerful device. For example, if any device has high processing power, RAM speed, battery life will show the high behavior value and get a chance than a low power device for communication.
- The greater the value of Free Resources the greater the possibility for the value of the Behavior to be with higher value. That means that the device which contains more free resources easily occupied for data communication.
- There is a linear relationship between Device Class and Path Influence Behavior which means that increasing the device class will increase the path influence value and may be capable of communication.
- There is an exponential relationship between Free Resources and Path Influence behavior which means that for any communication we need to increase the free resource value.

c. Comparison with Existing Algorithm

"Behavior of whole path" algorithm which is proposed in [1] is applicable for one topology contains 5 nodes. The proposed algorithm has removed this limitation. The proposed system is built to analyze any network topology for finding out an optimized path in order to node-to-node data communication.

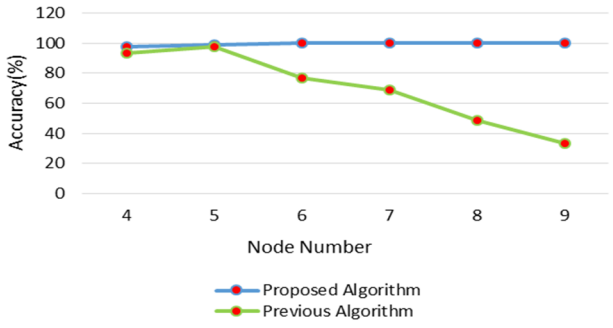

Fig. 5: Comparison of previous and proposed algorithm in respect of Node number

We have tested both previous [1] and proposed algorithm for 7 network topology samples contains several nodes. In Fig 5, X-axis shows the node number and Y-axis shows the accuracy of successful path and partner selection based on Path Influence Behavior. We can see that the accuracy of the previous algorithm is decreasing when we increase the number of nodes, but the accuracy of the proposed algorithm is near to constant that case.

V. CONCLUSION

In IoT network topology, path and partner selection for data communication is a very important and essential part. The proposed Path and Partner selection algorithm in Unstructured Resource Constrained Environment solved the path and partner selection problem when the destination node is more than one hop away from the source node in the hybrid flexible architecture. This algorithm can enable to discover the most suitable route for the need for a complete source-to-destination connection establishment. The proposed algorithm can also solve the contradiction when the Path influence behavior of two or more route is the same. Here, we examined seven samples including a variable number of node and evaluate the system by using a large set of data range. The performance is also measured by using summation and average calculation. In the end, we analyzed the relationship between Network parameters such as Device Class and Path Influence Behaviour from simulation result to validate the proposed algorithm.

VI. FUTURE WORK

The following enhancements can be further looked into:

- The Device Class and Free Resources parameter should be further researched and should increase the range.
- Should reduce the exponential time for decision making into logarithmic or linear time when a number of node are huge.
- Can introduce more network parameter, security mechanism and different priorities such as Emergency Priority which can classify the service type.

***Abstract*— Bridges are expensive and important constituents in the transportation network and any failure associated with it results in a huge loss of money, time and sometimes, lives. Bridges are important structures considering its use and purpose-serving. It may fail due to aging, loading conditions and natural disasters. Every bridge construction specifies a limit of weight of the vehicles that can ride it. However, still there is a very large record of bridge failures due to overloading. The proposed system is a wireless sensor network which monitors the weight of the vehicles on the bridge and provides immediate protection when the failure of the structure is nearly estimated due to excessive load. This design uses embedded sensors (piezoelectric sensors and accelerometers) over the bridge deck and its girder for the continuous governance of the bridge conditions. Data collected from the sensors are sent to a database server connected to the internet (forming an advanced wireless technology called Internet of things (IoT)) to activate traffic control when the limit crosses in order to eliminate high losses which would've occurred if the bridge have collapsed.**

Keywords—accelerometer, piezoelectric sensor, wireless sensor network, internet of things.

I. INTRODUCTION

Strength and Stability of a bridge are indications of the prosperity of a society and the safety of lives and properties of its dwellers. This makes the proper monitoring of bridges to preserve its strength an important issue. Strength to Weight ratio is a measure of a structures efficiency. It is the ratio of the structures weight to the weight it carries. A ratio>1 indicates stability of the structure. The proposed system ensures this ratio to be above 1 to prevent the bridge from collapsing. It employs a wireless sensor network (WSN) over the bridge that reports the state of the bridge to a remote data acquisition center. Due to all the inconveniences associated with the inspection of the health of such huge structure of a bridge, the development of effective and automated damage diagnosis techniques has been made possible through Wireless Sensor Networks. Based on the data collected simultaneously, the engineer will be able to estimate the state of fatigue or other limit states and provide forecasts of the probable stake of the bridges health and with modern technology, real time control of structures is accomplished. A WSN system consists of 3 units, a sensor unit (also known as sensor nodes), a remote data processing unit and an evaluation system. There are different methods for building up a WSN, which are discussed in the following literature review. This paper designs an IoT platform for monitoring the bridge state (both deck and girder) with automatic control action using arms barriers and spike barriers in case of any emergency. So the authority doesn't have to be at the bridge itself to ensure safety. Moreover, considering the cost of the system due to its great size, the cost can be minimized by cutting off the cost of power supplies i.e self-powering the sensor nodes. The system can thus be divided into 5 subsystems- energy harvesting, data collection, data transmission, data monitoring and control.

II. LITRTATURE REVIEW

Monitoring the strength of a bridge falls within the fields of Structural Health Monitoring of bridges. SHM aims to give, at every moment during the life of a structure, a diagnosis of the "state" of the constituent materials, of the different parts, and of the full assembly of these parts constituting the structure as a whole [1]. The SHM process involves the observation of a system over time using periodically sampled dynamic response measurements from an array of sensors. The basis of different structural health monitoring systems may be damage detection, loading condition, vibration based etc. Some commonly used sensors in SHM systems are mentioned briefly below,

A. Accelerometers

Accelerometers used for SHM are either piezoelectric or spring-mass accelerometers. Piezoelectric accelerometers are light, small, and operate over wide acceleration and frequency ranges [2]. On the contrary spring-mass accelerometers are heavier and requires large area and also operates over a limited range of frequencies.

B. Strain Sensors

Strain sensors used for SHM can be classified as piezo resistive or embedment strain gauge based. Cement-based strain sensors are typically piezo resistive and are capable of measuring strain. These sensors generate signals with an incredibly low frequency (< 1 Hz). Embedment strain gauges can be used for measuring strains inside concrete structures [3].

C. Corroision sensors

Strain Corrosion sensors typically measure the change in resistance introduced by the erosion of the sensor corrosion wafer. These sensors typically measure a structure's overall corrosion [11, 12].

D. Optical Fiber Sensors

The most common type of optical fiber sensor is the fiber Bragg grating sensor [13, 14]. These sensors can be used to measure parameters such as strain, temperature, pressure, and other quantities by modifying a fiber so that the quantity to be measured modulates the intensity, phase, polarization, and wavelength or transit time of light in the fiber. [15]

This project is based only on the general matrices i.e vibration, load, tilt or slope etc. There are different approaches

of implementing SHM of bridges starting from centralized approaches to distributed ones. The concept of distributed approach began with the development of wireless sensor networks. Besides data sensing, tracking and transmitting data is a challenge in SHM systems. With the advancement in technology, Internet of Things (IoT) has made it possible to integrate SHM with the Internet to track data anytime anywhere. In order to connect the sensors to the gateway wirelessly there are many protocols available such as Bluetooth, Zigbee, SIGFOX, Snow, Weightless, LoRaWAN etc. From comparative studies of these protocols it is clear that Bluetooth and Zigbee are compatible with small range IoT applications while SIGFOX, Snow and LoRaWAN are for large scale IoT applications requiring coverage area of few kilometers such as which we are working on. So far, the existing SHM systems are only monitoring which gives a record of the structures behavior for further studies or decisions such as one given in ref. [4]. However, none of them has an immediate protection. Adding an immediate protection feature would double its usefulness. The ability to prevent the breakdown of the bridge and loss of lives will give a clearer image of the importance of an SHM system. Also repairing the bridge before it collapses would decrease the maintenance cost to a greater extent. This implies the need of a bidirectional communication. However SIGFOX and Weightless are unidirectional. Snow is a network architecture that makes use of TV white spaces (allocated but unused TV channels) to operate. This makes a long communication range possible because VHF and UHF have excellent propagation characteristics over long distances and also a nice obstacle penetration, making communications in urban scenarios more reliable. This technology offers the possibility of deploying thousands of sensors and connecting them to the base station without the need to use either a multi-hop network or gateways[9]. Snow can cover large distances over 1.5km with relatively low transmission power, enabling longer life of batteries used in the sensor nodes. However, Snow is still under development and modules are not available yet. The advantages offered by Snow is also offered by LoRaWAN. The LoRa end device communicates with gateways that employ LoRa with LoRaWAN. LoRa gateways pass raw LoRaWAN packets from the end devices to a LoRa network server with a high throughput based on the backhaul interface, which is typically 3G or Ethernet. Accordingly, LoRa gateways act as a bidirectional communication or protocol adapter with the LoRa network server [10].

III. Internet of Things Platform for Bridge Strength Monitoring

At present the most efficient way to implement an SHM system is using IoT in order to monitor the structure from any location. The internet of things is a system of interrelated computing devices, mechanical and digital machines or objects that are provided with unique identifiers and the ability to transfer data over a network without requiring human-to-human or human-to-computer interaction [5]. It is a rising trend where enormous devices (things) are connected to the internet. To implement an SHM system using IoT, the required hardware components fall within 4 categories; sensors, microcontroller, transceiver and gateway. This design uses Accelerometers and Piezoelectric sensors at the sensor nodes to collect information about the state of the bridge (both deck and girders) and send it to a database server. The data is fetched and displayed on the web application for monitoring. In this design, we propose to ensure safety as data reaches the threshold by closing the entrance of the bridge immediately using automatic barriers or spike barriers which is discussed in section IV.

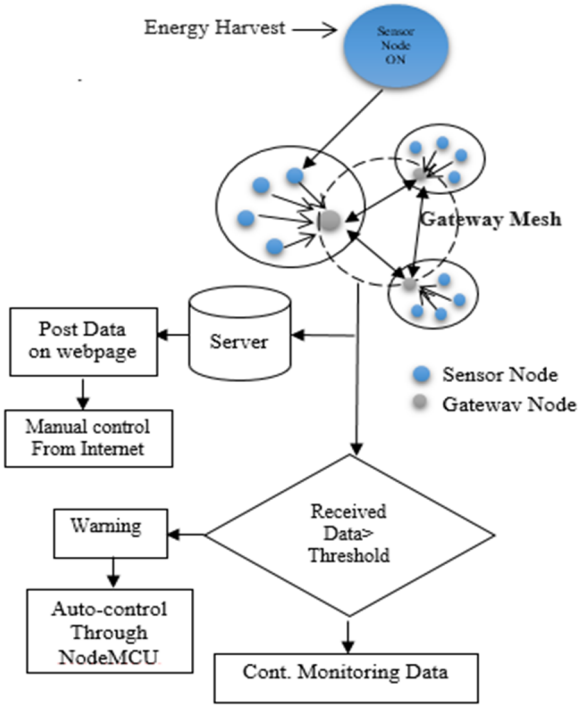

Fig. 1. Overall architecture

A. Sensors

1) Piezoelectric Vibration Sensor

Piezoelectric transducers respond to deflection, strain, vibration, flex, mechanical stress etc. by generating electrical charge proportional to the applied forces. Piezoelectric Vibration Sensors operate on the piezoelectric effect. A voltage is generated as the sensor is vibrated which is applied to the data pin of the microcontroller to be processed prior to transmission over the LoRaWAN network.

2) PiezoelectricPressure Sensor

Piezoelectric effect occurs not only due to vibration of the piezo material but also occurs when we pressurize the material. Besides piezoelectric vibration sensors we have used piezoelectric pressure sensors integrated in series which together, will measure the force on the bridge per unit area (pressure) by the vehicles to assure the pressure to be below the threshold value. The voltage that the sensor gives is proportional to the applied force, and by numerous calibration the resulting relationship between pressure and voltage for 2mm piezoelectric plate was found to be,

$$Y=0.02011X \quad (1)$$

Where, Y is the generated voltage (V) and X is the applied force (N). [7] The pressure created by the vehicles passing through the piezo sensor sheet (a sheet prepared by connecting a large number of piezo sensors in series to cover up a wider space to increase accuracy in measurement of the force applied) is measured by the given formula.

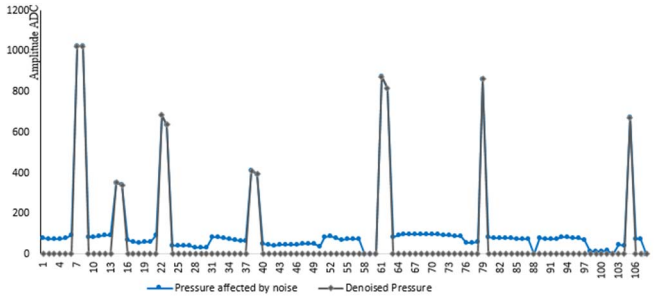

Fig. 2. Vibrational noise compensation using microcontroller

The vibration of the bridge will also affect these piezo sheets. However the voltage generated due to vibration has very small amplitudes compared to those generated due to mechanical force. The compensation to this low amplitude noise is performed by the microcontroller used. The blue lines in Fig. 2 shows noise due to bridge vibration. These low amplitudes are clamped down to 0 level by the microcontroller. The resulting undisturbed response of the piezoelectric pressure sensor is represented by the grey lines. Upon filtering out the noise, the voltage is converted to pressure and transmitted over the LoRaWAN network and received in the gateway to pass it to the database server. Readings from all the sheets within the unit area are integrated and compared simultaneously with a threshold value.

3) ADXL335 Accelerometer

On a bridge, not only the deck gets damaged but also the girder, on which the bridge stands, may get damaged especially in cases where the bridge is built over a river. The angles at which the girders are built is fixed and any deterioration suspects a collapse of the bridge**.** ADXL335 has been chosen to detect this in this design. It is a small, thin, low power, complete 3 axis accelerometer with signal conditioned voltage outputs. It can measure the static acceleration of gravity in tilt sensing applications, as well as dynamic acceleration resulting from motion, shock or vibration [6]. Acceleration is measured by ADXL335 in g unit. Max voltage for 0g is 1.65V. From the X_{out}, Y_{out}, Z_{out} output of the module, we calculate the angle of inclination.

$$A_{xout} = \frac{\frac{X_{out} \times V_{ref}}{1024} - 1.65V}{.330V} \quad (2)$$

Similarly we calculate for A_{yout} and A_{zout}.

The angle of Inclinations are calculated from the formula,

$$\theta = \operatorname{atan}\left(\frac{A_{xout}}{\sqrt{A_{yout}{}^2 + A_{zout}{}^2}}\right) \quad (3)$$

Similarly we calculate for angles ϕ, ψ. As an inclination is detected on any girder, immediately the entrance of the bridge will be closed.

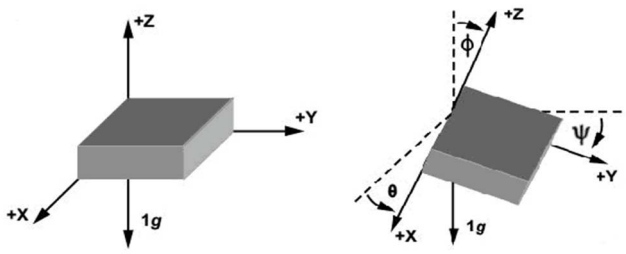

Fig. 3. Illustration of angle of inclination [17]

B. Microcontroller

Microcontrollers processes the data before transmitting it, For IoT applications, to exchange data between web server and web applications, the data collected is converted to JSON format by the microcontroller and fed to the web application from the server. There are 3 different typical microcontrollers which are used in WSN application. They are Microchips, AVR series and MSP430 series. More of which can be known from the reference [8]. For prototyping, one of the most successful and most popular microcontrollers is the Arduino platform. Arduino is a development board that houses a microcontroller on it. To make the nodes as small as possible, Arduino Nano can be used to implement the sensor nodes

C. Transiever

Each node transmits and receives data over the WSN via a transceiver. The right transceiver to be employed is chosen depending on the size of the network. LoRa (Long Range wireless data telemetry) technology is the most exciting technology for longer range communication. LoRa technology offers a 20dB link budget advantage compared to existing solutions, which significantly extends the range of the application while delivering the lowest current consumption to maximize battery life [Semtech], fulfilling all the requirements of the transceiver an SHM system for bridges might require.

D. Gateway

The topology of the nodes and the gateways is an important issue considering the huge size of the structure. ESP8266 is a low cost Wi-Fi module chip that can be configured to connect to the internet for IoT applications. However it has been designed without any holes for pin headers, it is meant to be mounted on a PCB. ESP8266 NodeMCU is preferable for easy bread-boarding and can directly be connected to a computer to start writing programs and connect to the Wi-Fi network.

In case of designing a large scale IoT system such as that one for monitoring a bridge, the availability of the gateway, without crashing or any security breaches is important. A peer-to-peer connectivity between a large numbers of gateways can be employed. This constitutes a number of gateways connected to one another via a mesh network and clusters of sensor nodes to each gateway as shown in Fig. 1. If one goes down, the redundancy of that network ensures reliability and the continuity of the cloud communication for commands and storage of data. During a failure, IoT gateways can transfer their applications and device connections to one another.

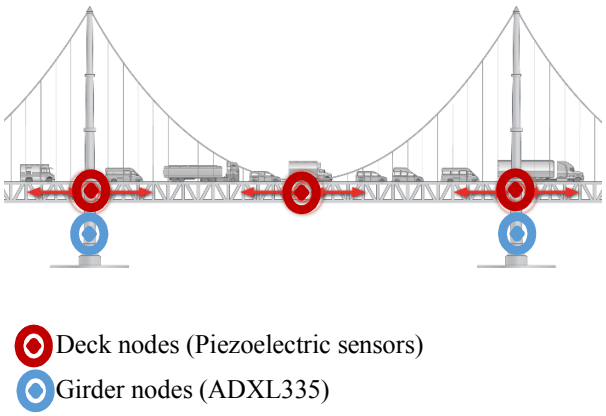

Fig. 4. Distribution of sensor nodes

E. Self Powered Sensor Nodes

IoT applications faces a puzzle to solve the issue of limited energy resources. A solution to this is adding energy harvesters. IoT and energy harvesting is a perfect match for monitoring applications. As energy harvester Solar panel is the best choice as solar power is certainly the cleanest form of renewable energy available. The solar panel must provide sufficient current to power the Arduino and also charge the battery pack during the day. So only connecting it to a charging circuit won't do any good as eventually the charge won't be sufficient for the entire day if the sensors consumes very high power. In most cases of SHM using WSN, the Arduino read the sensors periodically and transmit their values then it usually enters sleep mode until it reaches the next sampling time. During this idle time, instead of putting the Arduino into sleep, which won't save much power as other peripherals (sensors and communication modules) keep working, we can employ a timer circuit, which turns the power on/off periodically. When the Arduino is ON the sensors will read and transceiver will transmit the data. After that the timer circuit turn the Arduino OFF for few minutes and then restart the entire process again.

A 555 timer circuit operating in the astable mode can be used for this operation. In astable mode, the 555 timers output voltage alternates between Vcc (+5V) (high state) and GND (0V) (low state). The frequency of the wave can be adjusted by changing the values of 2 resistors and a capacitor connected to the chip. The timer circuit is shown in the Fig. 5. It consists of a 555 timer, resistors, capacitors and a diode. By changing values for R1, R2 and C1, the frequency can be altered (the length of ON time and OFF time. Increasing C1 or R2 will increase both the ON time and OFF time which Increasing R1 will increase the ON time without affecting the OFF time.

Mathematically, this is represented as,

$$Ton = 0.69 \times C1 \times (R1+R2) \quad (4)$$

$$Toff = 0.69 \times C1 \times R2 \quad (5)$$

Where,

Ton is the time (seconds) during which o/p pulse is high

Toff is the time (seconds) during which o/p pulse is low

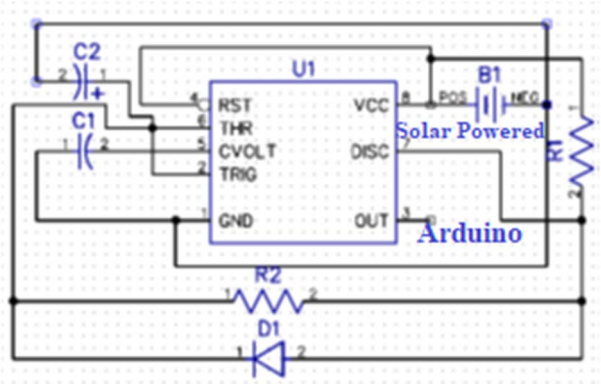

Fig. 5. Timer Circuit Schematics

Minimum duty cycle for this kind of circuit is 50% (Half time ON and half time OFF). To increase the OFF time beyond the ON time, a simple logical inverter method at the output of the timer is employed. This way the values of R1, R2 and C1 is chosen (2 MΩ, 1 MΩ and 47 µF respectively) so that the duty cycle is close to 75% (before the logical inverter). After the inverter output it is ON only for 25% of the time (32.57 seconds ON and 97.71 seconds OFF, resulting duty cycle is 25%). The inversion is performed by using a diode parallel to R2.This extends the battery charge to power the nodes up to few consecutive days which is an advantage really needed during non-sunny seasons.

IV. Experimental Results

For initial testing, ThingSpeak was used as our database. ThingSpeak is an open source Internet of Things (IoT) application and API to store and retrieve data from things using the HTTP protocol over the internet or via a Local Area Network [16]. Data is fetched from ThingSpeak and enrolled on the logger section of our designed webpage in which the bridge state is monitored and controlled. The control strategy is divided into 2 categories. One is control via spike barriers and the other is through arm barrier. The entire bridge is divided into regions of 0.5km, each region separated by a spike barrier (inactivated). The data collected are compared against a threshold value in the NodeMCU gateway serving the corresponding region and if it reaches the threshold point, the NodeMCU automatically sends a command via the LoRaWAN network to the control node to activate a spike barrier to stop vehicles approaching the overloaded region. A warning is given to the drivers on board prior to activating the spike barriers. Tilt of the girder is also monitored and when it reaches the threshold the entrance of the bridge is closed by an arm barrier in the same way. The authority can also close the entrance through the internet only by a click on the webpage provided suspicious behavior in the bridge. As this is done through the internet, the authority can take immediate step from any location. An image of our logger for deck monitoring is provided in fig. 6. This displays the data transmitted by the sensor node 100.

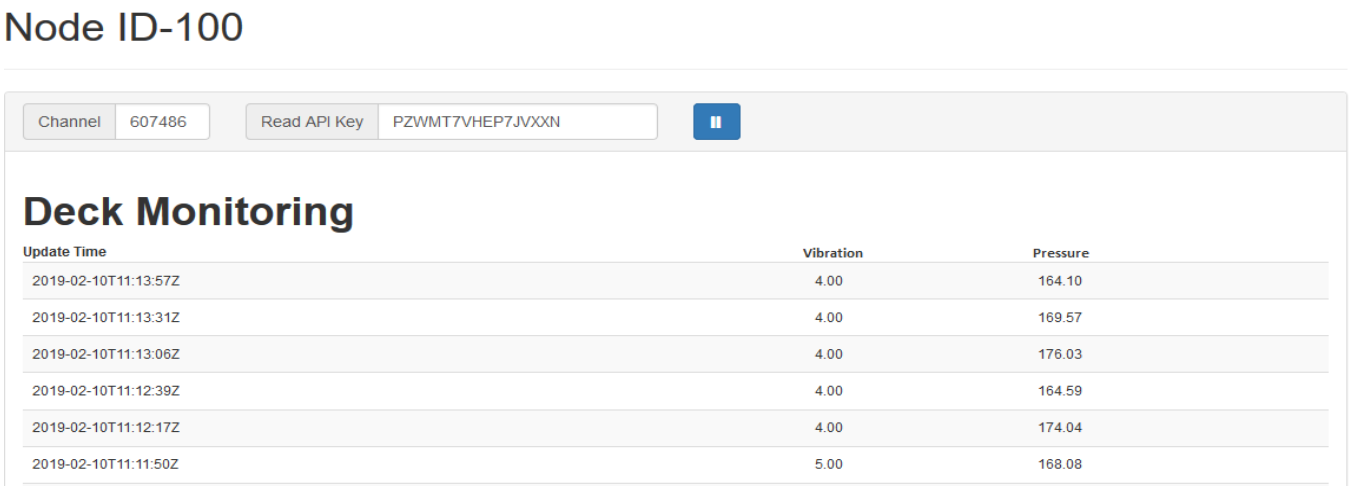

Fig. 6. Deck Monitoring logger for NODE 100

V. Conclusion

Every year breakdown of bridges cause a huge loss of lives and properties. Thus preservation of the strength of a bridge has become a paramount mission. Our proposed system not only decreases the stake of lives but also decreases the cost of maintenance of the Bridge by taking preventive moves. Undoubtedly, the maintenance of a bridge before it collapses is a lot lesser than that of a bridge that has already collapsed .

***Abstract*— Agriculture represents a significant index in the evaluation of rural areas of Bangladesh. In order to increase the productivity of crops, a smart irrigation system is needed. Using GSM and IoT technologies, the proposed system makes the agricultural cultivation process more automated. The IoT technology makes the irrigation system capable of monitoring the field and taking the decision to irrigate automatically. The power generated from the solar PV system is the main power source of the proposed system. The sensor is installed on the agricultural field which is frequently sensing the water level. Without visiting the agricultural field, farmers can get information about the water level. When low moisture is detected, then motor is turned on and when moisture is normal then motor is turned off. After that, it sends data to GSM module sim900A which gets information about the motor in the farmer's cellular phone. To transmit and receive the sensor information, Message Queuing Telemetry Transport (MQTT) system is used in the project. By detecting the status of Soil Moisture Content, GSM module controls the water pump status and displays the condition of Soil Moisture Content through a server or mobile application.**

Keywords— Smart irrigation, GSM module SIM 900A, The Internet of Things, MQTT, A Solar photovoltaic system, The Moisture sensor

I. INTRODUCTION

Agriculture is the largest employment sector in Bangladesh. Most of the Bangladeshi people earn their living from agriculture [1]. Farming stands the basic factor of Bangladesh economy, contributing 19.6% to the national GDP and giving employment for 60% of the total population [2].Farmers rely on the monsoon because of water needed, which is insufficient. So the proposed system is concerned, which automatically irrigate the plants depends on the soil moisture condition and atmosphere type [3]. Reducing the waste of water is an important concern. The IoT based automated irrigation system increases the efficiency of cultivation. The moisture sensor is used which observes the plants condition & level of water from distance. To reduce the waste of water and monitor the irrigation system, IoT gets the best results using innovative techniques. MQTT protocol is used in the system. So the proposed GSM and IOT based irrigation design is energy saving and also cost effective [4]. In this paper the system is designed for a remote area like Charandeep, Chakaria, Cox's Bazar. Most of the people in this area are dependent on agriculture, but this area has no grid connection. Petrol, diesel, kerosene etc are used as the fuel source of plant irrigation. This type of sources is not environment-friendly, because of the carbon dioxide emission. The proposed MQTT based smart system presents an idea to use the sunlight as the power source which can fulfill the demands of irrigation in this area. The source is environment friendly and also cost effective.

II. LITERATURE REVIEW

Reduction of waste of water and consumption of nonrenewable energy sources are confirmed by using multiple craftsmanship and technology [5]. If its' energy sources are low cost, then the system is useful to the area (Charandeep) and using GSM Technology for observing and controlling the cultivation method except farmer visiting [6]. Using renewable energy sources like sunlight, the wind has been utilized power consumption [7]. Agricultural sector is improved rapidly using smart technologies [8]. Different types of IoT equipment are available in the market which makes smart irrigation process more automated [9, 15]. The rural area like Charandeep, 80% of the farmers still improvised. So the high cost of equipment buying is not economically viable [10]. Automatic irrigation techniques irrigate using a wireless sensor network, i.e. Zigbee and internet technology [11].To improve the productivity of the crop, there is an immediate change of the manual method from automatic method [12]. The accurate observing of the field data and controlling the cultivation process is being automated through IoT and GSM technologies by taking real time data from the field [13, 17]. The literature review represents that difference between the previous, present and proposed system. The previous state represents that manual based ordinary pump is used where the power sources are diesel, petrol and kerosene. So the system is not suitable for the environment and also costly. The present state has used the power of a source of conventional and renewable energy which energy is cost effective and energy efficient. The proposed system is based on solar driven irrigation system to accumulate GSM technology, MQTT and solar power. So this system is not only energy efficient by using solar power

but also serving the fastest communication on agriculture field. The proposed system also developed an agriculture farm which has different types of crops such as tomato, chilies, brinjal and paddy etc. So, different types of crops need different water level. The analogue pin of Arduino and the moisture sensor probes detect different types of crop water level, which turned on/off the motor. Using sensors in a field area with four sites of corners which supply the water in the field is balanced.

III. PROPOSED SYSTEM

In Fig: 1 represents the block diagram of proposed system. Photovoltaic (PV) cell converts sunlight into electricity directly. Solar power is the main source to drive the whole system. This power will be stored in a dc battery which is used as the backup when solar irradiance is not appropriate for the system. The moisture sensor, Arduino, GSM sim900A and cell phone interface are driven by dc power. The moisture sensor senses the level of water. When sensor senses the low/high moisture, the motor turns on/off automatically. This condition of the field will notify farmer's cellular phone through GSM sim900A. A Jason format links the motor status (On/Off) automatically to the server via MQTT broker. The server can view the motor condition of the field. The MQTT protocol system is observed by the computer system using internet. However DC pump is driven by the dc power through the motor driver circuit. The user can see the motor turn on/off condition and field moisture dry/wet condition in smooth TFT display.

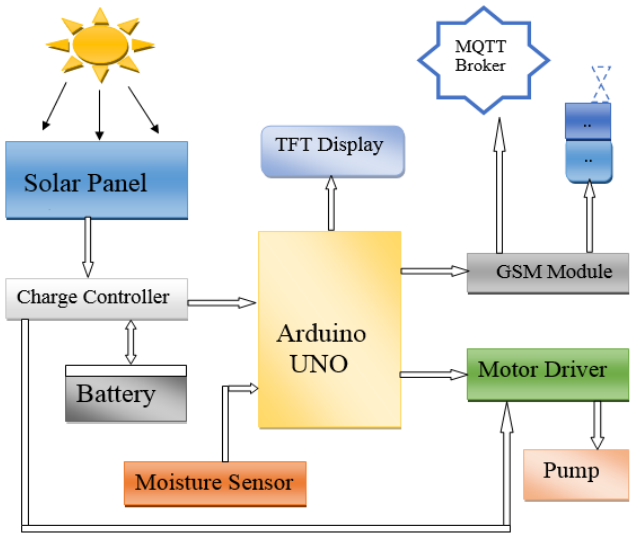

Fig.1. Block Diagram of Proposed Model.

The solar irradiance and clearness index play a vital rule for solar energy conversion. The proposed system designed for Charandeep, Chakaria, Cox's Bazar is encouraged by following NASA solar irradiance and clearness index Fig: 2 and fig. 3.

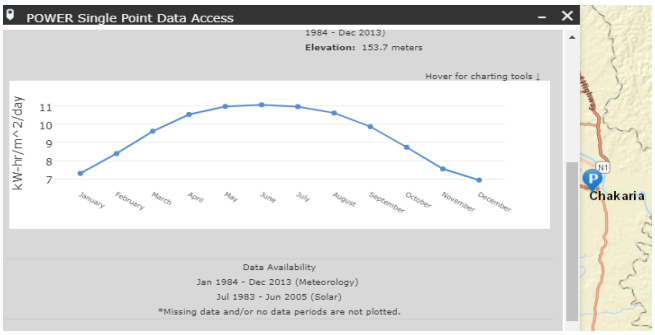

Fig.2. NASA solar irradiance for Chakaria zone [14]

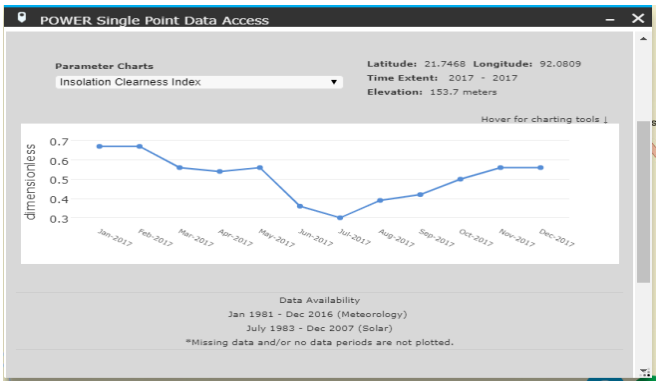

Fig.3. NASA clearness index for Chakaria zone [14].

So this nonconventional source of energy is appropriate for this rural area.

IV. HARDWARE COMPONENTS

Solar Panel:

The solar energy comes from resources which are continuously replenished such as sunlight. Solar cells operate by converting sunlight directly into electricity. This energy will improve the quality of our environment. It's the main source of power in the proposed system.

TABLE I. Specification of solar panel.

Name	Specification
Power	20W
Voltage	17.46V
Current	1.15A
V_{oc}	21.16V
I_{sc}	1.28
Operating Temperature	-40^0C to $+85^0$C

GSM MODULE SIM900A :

GSM uses variation of time division multiple access (TDMA).GSM module sim900A controls the overall system. This module need minimum (1.5A =2A) power source.

TABLE II. Specification of GSM Module SIM 900A.

Name:	Specification
GSM Module	SIM 900A
Frequency	900MHz/1800MHz
VCC5	5V
VCC4	3.3V - 4.5V
Rated Current	1.5A < 2A
Size	(5.6 cm x 4.9 cm x 2.8 cm)
Weight	23g

MQTT PROTOCOL

It is a simple messaging protocol and a perfect solution for internet of things application. It allows to sends command to monitor and controls the output and communicates among multiple devices.

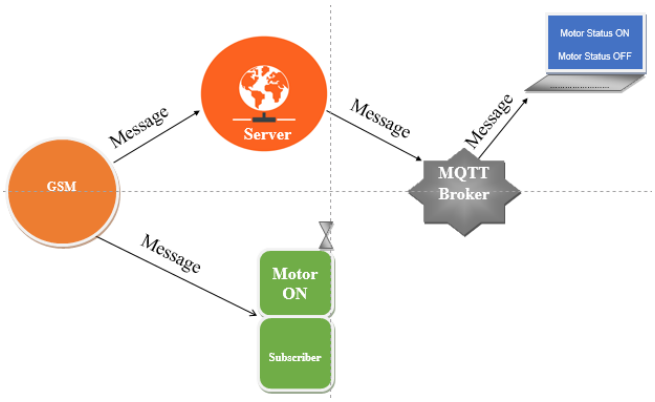

Fig .4. MQTT protocol system.

Message Queuing Telemetry Transport (MQTT) VS Hyper Text Transfer Protocol (HTTP).

- MQTT is data centric whereas HTTP is document centric.
- HTTP is request-response protocol for client-server computing and not always optimized for mobile devices whereas MQTT provides publish/subscribe model clients with independent existence from one another and enhance the reliability of the whole system.
- According to measurements in 3G networks, throughput of MQTT is 93 times faster than HTTP's.
- MQTT uses low bandwidth whereas HTTP uses comparatively high bandwidth.

So MQTT is better than HTTP for IoT development [16].
MOISTURE SENSOR:

The moisture sensors identify the water level of agricultural field. When the water level of farming field is become dry/wet then the moisture sensor's digital output is low/high.

TABLE III. Specification of soil moisture sensor.

Name	Specification
Power indicator	Red color Led
Digital Switch indicator	Green color led
Operating voltage	3.3-5V
Digital output interface (0 and 1)	DO
Analog output interface	AO

V. DESCRIPTION OF PROPOSSED MODEL

A. Flow Diagram of proposed model :

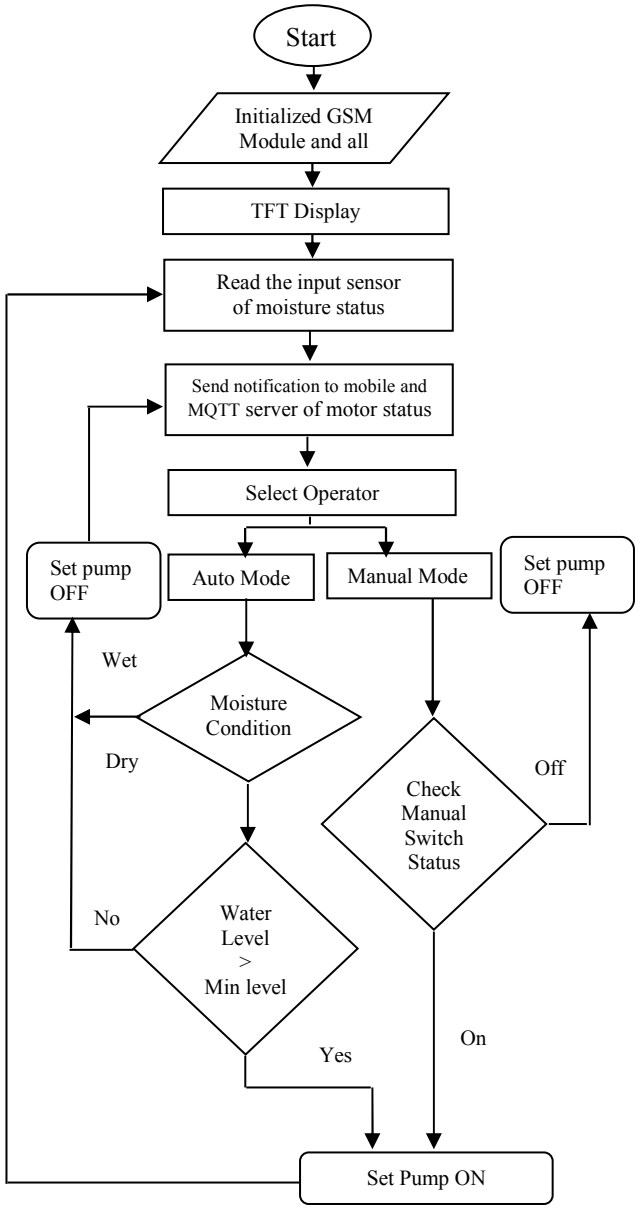

Fig.5. Flow Chart of Proposed Model.

Description of flow chart proposed system:

The following steps involved are working on a system are mentioned below:

Step 1: Power is supplied to the proposed system which initializes GSM and all.
Step 2: After initializing the system, the TFT display shows "MOISTURE BASED PROJECT".
Step 3: The input module moisture sensor senses the moisture condition of farming field and transmits a digital data to the Arduino.
Step 4: Arduino checks the mode operation. If the mode is manual then it cannot operate automatically. Then it depends on farmer's feedback.
Step 5: When the mode is auto then it will operate from step 6 to step 12.
Step 6: The moisture sensor senses two types of moisture condition. I,e (wet/ dry).
Step 7: If the moisture is wet, the moisture sensor sends a digital data to the arduino.
Step 8: Arduino receives this digital data and checks the logic. If the logic is low moisture then the motor is "ON" through the motor driver circuit and also transmits a data to the GSM SIM 900A.
Step 9: The GSM SIM 900A receives this data and sends a notification to the farmer's cell phone " Low soil moisture detected. Motor turned ON" and at the same time sends a notification to the server through MQTT protocol.
Step 10: If the moisture condition is dry then the module transmit a digital data to the Arduino and check this data.
Step 11: If the condition "Water level > Min level" is true, then the pump is turned off through motor driver circuit and also sends a signal to the GSM module SIM 900A.
Step 12: The GSM sends a notification to the farmer's cell phone "Soil moisture is normal. Motor turned OFF" and at a time sends a notification to the server through MQTT protocol.

B.CIRCUIT EXPLANATION

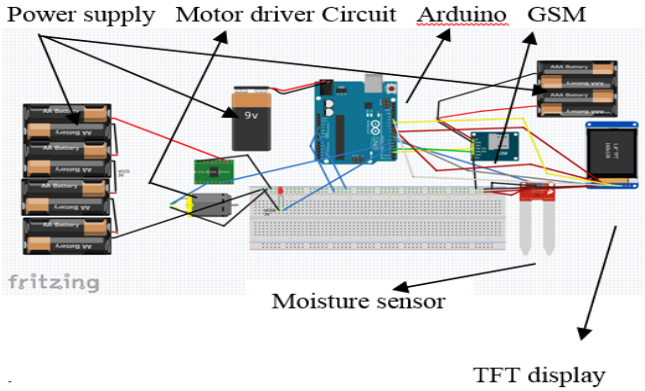

Fig.6. Circuit Diagram of Proposed Model

Power supply:

The power is supplied from the solar power. The solar power voltage is not a uniform voltage. Solar charge controller is used for supplying uniform voltage to the load and control system. To store the power, a 12V DC battery is used. The battery supplies the power when solar power does not work at adverse condition.
Charge Controller Connection:

Solar voltage output is connected to the charge controller input terminal. Battery is connected to the storage terminal and motor system is connected to the load number 1 or load number 2.

Motor connection:

The output of the Charge controller is 12V which is connected to the motor driver input 12V. The motor driver output 12V is connected to the pump and ground terminal is connected to the ground. The pump is controlled by the Arduino digital output through the motor driver circuit.

Moisture sensor connection:

- The moisture sensor Vcc pin connects to the 5V power supply.
- GND pin is connected to the ground.
- Digital input, output pin (D_0) is connected to the Arduino digital pin D_6.

GSM Connection:

- GSM module 900A is power supply takes from 5V, 2A circuit for a dedicated power supply.
- GSM SIM module 900A TX pin is connected to the Arduino digital pin D_2.
- RX pin is connected to the Arduino digital pin D_3.
- GND pin is connected to the ground.

Display connection:

- The 1.8 TFT display module RST pin is connected to the Arduino digital pin D_7 through the 1K resistor.
- CS pin is connected to the Arduino digital pin D_9 through the 1K resistor.
- D/C pin is connected to the Arduino digital pin D_8 through the 1k resistor.
- DIN pin is connected to the Arduino digital pin D_{11} through the 1k resistor.
- CLK pin is connected to the Arduino digital pin D_{13} through the 1k resistor.
- Vcc/BL is connected to the 5V supply.
- GND pin is connected to the ground.

EXPERIMETAL SETUP OF PROPOSED SYSTEM

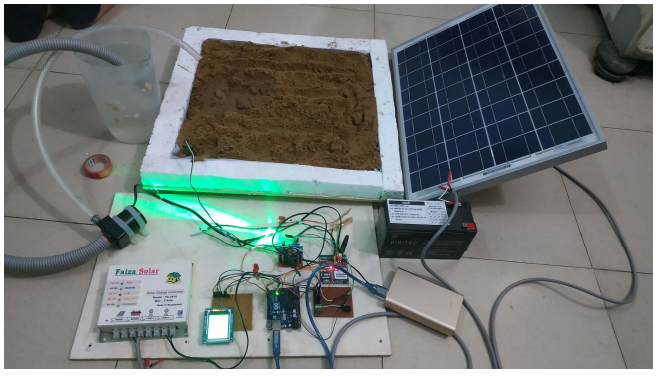

Fig.7. Experimental setup of proposed system

VI. RESULT PART

The screenshot of the moisture condition in the TFT display as bellows:

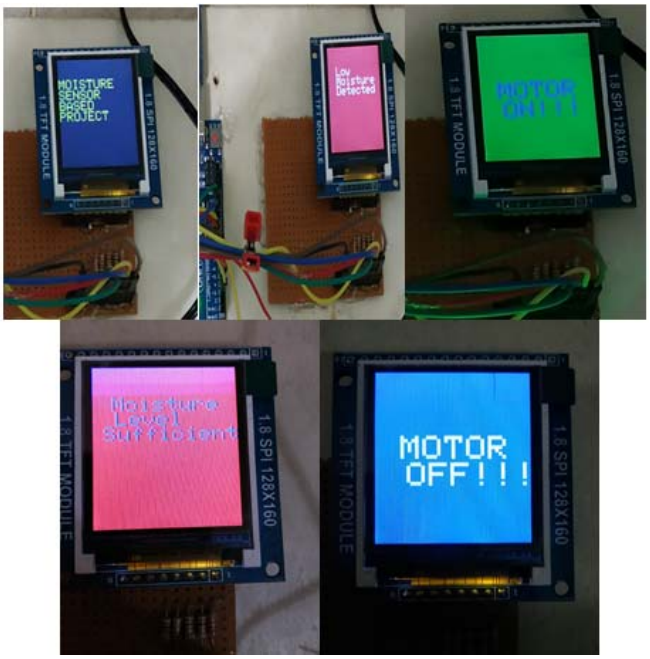

Fig.8. Pump status in TFT display.

The following fig: 8 and fig: 9 of pump status is sent to the farmer's mobile phone via GSM technology. When the moisture sensors detect the low moisture, then it sends a notification to the farmer's mobile phone as "MOTOR ON". Whenever the moisture sensor detects the moisture is normal, then send the notification "MOTOR OFF".

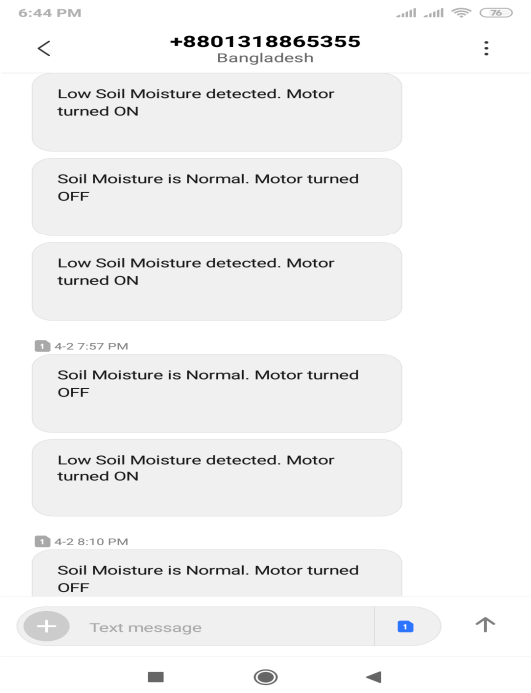

Fig.9. Pump status in farmer mobile phone

MQTT broker system carries the JASON format link to the subscriber's web server of Motor status to monitor and control the system as Following fig: 10 and fig: 11.

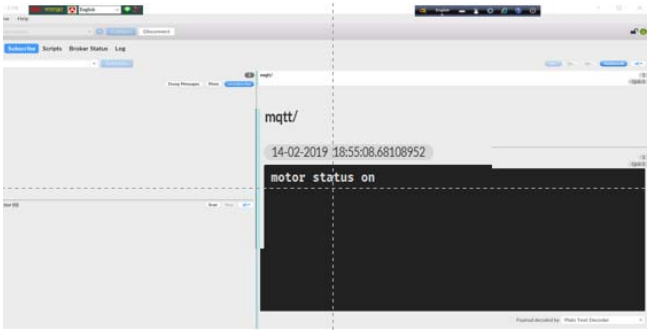

Fig.10. Pump "ON" status monitoring in the server.

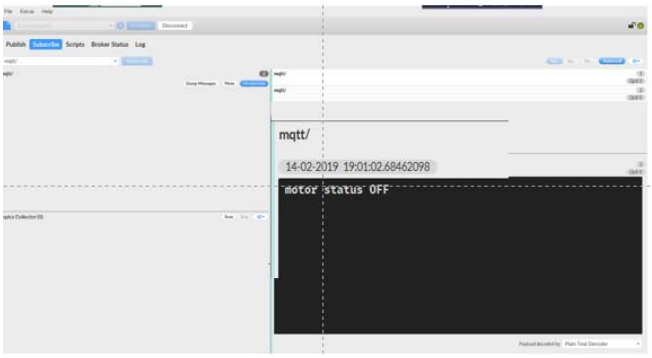

Fig.11. Pump OFF status monitoring in the server.s

VII. CONCLUSION

To increase the productivity of crops, farmers need automatic and IoT technology in the irrigation system which provides more comfort to farmers. To require less human intervention and minimum maintenance for agricultural fields, the system is feasible to use conveniently for all farmers. Moreover time is saved and water is used accurately without wasting. MQTT is used which communicates with multiple devices. It's lower bandwidth and low power consumption makes the proposed system cost effective. This project can be a suitable alternative to overcome the necessity of uninterrupted supply of electricity in irrigation system of our farmers. The system can be implemented in rural areas (Charandeep, Chakaria) with a lower investment.

***Abstract*—The amount of death rate in Bangladesh because of different types of non-communicable cardiac diseases are rapidly increasing every year. These non-communicable diseases are long-term and slowly progressive and become so severe that the condition of a patient is too critical to handle. As a result, most of the people getting a sudden heart attack or learn about their disease when it is too late. Thus, in this paper, we propose an IoT and Machine Learning derived cardiac status prediction method that can collect necessary data from human body using IoT devices (sensors) and transfer those data to the cloud where the data are stored with user authentication. The data which are received from the human body are then to be normalized before machine learning algorithms are applied to them to calculate and predict the overall condition of a patients heart. To-date we could collect heart rate, ECG signal, and cholesterol through IoT devices from the human body. The results we have received of heart rate and cholesterol are quite satisfactory. There are still some issues with the interpretation of the ECG signal which we are working on.**

***Index Terms*—IoT, Machine Learning (ML), Cardiovascular Disease (CVD), ECG, Cholesterol, Heart Rate.**

I. Introduction

Cardiovascular Disease (CVD) and Coronary Artery Disease are two increasing cause of mortality nowadays in Bangladesh. Over the last few decades, the main reason for death has dramatically shifted from communicable disease e.g.Cholera, Smallpox to non-communicable e.g. Cardiovascular disease, Cancer, Blood pressure, Diabetes disease. Previously from a statistics of 1986, the morbidity and mortality for the communicable disease were 52% and for the non-communicable disease, it was 8% [1]. But according to some studies done in 2014, it has been found that the main cause of death has dramatically shifted to non-communicable disease from communicable disease, which is quite severe in the sense because non-communicable disease like Cardiovascular disease is the most fatal reason of death bearing the statistics of 17% alone [1]. The effect is higher in urban areas although the available treatment for the cardiac disease is quite costly. So looking through different aspects of CVDs in our country it is safe to say that, this side needs some attention and some measures have to be taken to monitor the cardiac condition as well as to get useful suggestions or alerts for upcoming anomalies of a person's cardiac condition.

Thus, in this paper, we describe a prototype which will automate the whole task of data collection and transferring the data with the help of IoT devices to an application running a Machine Learning algorithm on the cloud, which will then calculate the result based on the inputs collected from different IoT devices and sensors connected to the patient or user-end in real time. The ML algorithm is provided with 12 parameters to get a prediction about the possible cardiac anomalies.

Cardiac diseases are highly prevalent in Bangladesh. The death rate is increasing rapidly due to the rising amount of heart attacks, Coronary Artery Disease, Cardiovascular Disease (CVD). According to the Global Health Observatory data of the World Health Organization in 2017 Bangladesh is ranked 104 in the world with 14.31% of total deaths.

According to the recent Non-communicable Diseases Country Profiles of Bangladesh provided by WHO, the number of people who are taking drug therapy to prevent heart attacks and strokes is negligible. People are barely conscious of non-communicable diseases but these long-term and slowly progressive diseases are so severe in future that condition of the patient becomes too critical to handle. According to Bangladesh criteria, people hardly follow a regular checkup or feel the necessity to counsel a doctor even once a month. As a result, most of the people got a sudden heart attack or get to know about their disease when it is too late. So all of these situations motivated us to come up with IoT devices based on ML driven heart condition monitoring system. A device that will take all the necessary sensitive and private data from human body such as Cholesterol, Heart rate, ECG, Blood sugar and Blood pressure and so forth with the help of IoT devices and our Machine Learning algorithm will calculate the result

and provide the overall heart condition of the patient.

Blood pressure monitor, glucose meter devices are popular and useful among people as these devices measure blood pressure, blood sugar level which let people know their current health status within a minute. This service is not available yet for non-communicable disease patients. Hence, a device that can let people learn about their current heart condition will be helpful to take the necessary preventive steps at the right time.

The rest of the article is organized as follows. Section II provides a review on existed works related to IoT based health monitoring systems. Section III presents our proposed methodology on cardiac diseases detection and Section IV demonstrates our experimental analysis and results. Finally, Section V is the conclusion including our future progress and improvement.

II. Related Work

In this section, we have reviewed the existing works related to cardiac issues that already have been done or people still are working on.

A. Blood Pressure and Heart Rate

There is a paper by Snehal Sanjay Kale et al. in [2] where they introduced BSN technology, which is consisted of low-power and lightweight wireless sensor nodes, such as temperature sensor, heart rate sensor to collect blood pressure and heart rate of a patient. These devices are placed on the human body to monitor the health condition of a patient at home and all of these collected health-related parameters will be sent to their physician's server using a long-range wireless technology.

We-Care [3] is an IoT based health care system which introduced We-watch wristband using a SensorTag from Texas Instruments. This wristband is for elderly people which collects blood pressure, humidity from the human body. It can also detect a sudden fall of the patient. The Fall Detection system is implemented by reading the accelerometer data which is used to detect sudden movements, like falls, and also to track any movement activity performed by the elderly person.

A paper by P.Gupta [4] presented an IoT based system which provides emergency medical service by collecting data information through health status monitors including heart rate, blood pressure, and ECG. These pieces of information are sent to the patient's doctor as an emergency alert with full medication information.

In paper [5], Johan Bhurney et al. used the photoplethysmography method via the PPG sensor to detect the variations in blood volume and blood flow in the body.

B. Electrocardiography

In paper [6] the authors have proposed a health monitoring and measurement system by inexpensive wearable sensors. The sensor will collect some physiological parameters and will transmit the data to a gateway server via Bluetooth. The physiological biomarkers that are taken into consideration are ECG, Respiratory rate, Skin temperature, and EMG muscle movement.

Paper [7] mainly focuses on electrocardiogram of a patient through IoT enabled sensors. Despite conventional clinical ECG equipment has 12-lead system, this proposed system implements 3-lead placement in a triangular fashion around the heart. The data is processed through an MCU and sent to the cloud with wireless access points.

In work [8] the researchers mainly worked on developing a software infrastructure that supports ECG signal analysis for feature extraction and classification for diagnosing the heart condition. The features space extracted for the ECG signal led to an accuracy of 98.7%. They also made it clear that ECG analysis and classification can be done in real time.

Paper [9] describes the way of measuring physiological ECG data using a single board computer with the help of e-health sensor platform. The ECG data is processed to get the Heart Rate(HR) and Heart Rate Variability (HRV) which later on will be used to diagnose major diseases.

C. Glucose and Cholesterol

In the work by Meghana Chandrashekar et al. a Near-infrared sensor is used to measure the glucose level of a person which can measure the glucose level without the blood samples from the human body. Another used sensor is BMI sensor which can measure the cholesterol level of a person. In this process, a signal is passed through the human body and the sensor waits for the receiving time of the signal on the other side and then the cholesterol level is calculated based on that time. There are two parts - software and hardware. The software application will monitor a persons health by measuring the blood glucose level and cholesterol level of the human body. The hardware kit is made of Infrared sensor and BMI sensor which helps to measure glucose and cholesterol level to monitor a persons health.

In the work of Mr. Li et al. [10] consider some parameters as the vital element of heart condition prediction e.g. (Blood pressure, ECG, SpO2, Heart rate, Pulse Rate, Blood glucose, Blood fat). For intermediate communication Bluetooth and long distance communication Cellular network, Wireless network is used.

In the paper of Mr. Gomez et al. [11] described the statistics of the mortality of patients suffering from different chronic disease. It appears to be that, most of the patients dying from heart failure have been suffering from Overweight 2.6M, Elevated Cholesterol 4.4M, Blood Pressure 7.1M. Therefore, detecting these vital of the patients on a regular basis and sending them for monitoring to a specialist was their main objective. But they described that due to technological limitations these devices are not smaller quite yet. Although some devices e.g. Glucometer, Wrist blood pressure cuff, HRM including electrocardiogram is available today.

III. Methodology

In this section, we have described our proposed method including the list of parameters required in our work. An overview of the entire prototype design and our implementation so far on 3 parameters (heart rate, ECG, cholesterol) are also explained.

A. Parameters

Our main concern is the cardiac issues of patients so, we would need to collect data-set of patients related to cardiac disease. From the previous study done on the field of cardiac disease, there are actually a total of 75 numbers of parameters. Among them, researchers have worked on 14 parameters with Cleveland data-set till now and the result for the 14 parameters have proven to be accurate enough to continue the research on 14 parameters only. Furthermore, we have seen 12 parameters also provides a similar result. So, these 12 parameters mentioned below would be sufficient enough to provide us with an accurate prediction of a patient's cardiac condition. The parameters below given are associated with their respected available sensors.

Parameters through manual input:

1) **Age:** According to this paper, at age 40 the lifetime risk of developing heart disease is one out of two for men and for women it is one out of three. If we consider age as 70 the statistics suggest that it is one out of three for men and for women it is one out of four [12].
2) **Gender:** Heart disease is more seen among the middle-aged people especially it is two to five times more common in men than it is in women [13].
3) **Chest pain type:** Chest pains are the most common symptoms indicating different Cardiovascular disorders. So that's why it is chosen as one of the parameters.

Parameters through IoT devices:

4) **Resting blood pressure:** From the paper of J.Gomez [11] and C. Li et al. [10], we get the numbers from which it appears that most of the patients dying from heart failure have been suffering from Overweight 2.6M 4.4M, Blood Pressure 7.1M. Which leads us to choose RBP (Resting Blood Pressure) as one of the parameters.
5) **Cholesterol:** Elevated cholesterol is one of the major cause of death among people having heart condition said by J. Gomez et al. in [11].
6) **Fasting blood sugar:** Fasting leads to loss of weight and reduction of blood sugar whereas it is considered a level of less than 100 mg/dL is normal. Which is why it was chosen as a parameter for generating the cardiac prediction of the patient.
7) **Resting ECG:** ECG stands for Electrocardiograms. ECG is used for detecting cardiac arrhythmia [8]. Which is essential because we need to observe the condition of the heart of a patient and detect different anomalies. ECG helps us to do that. Besides we can calculate the hear BPM with ECG.
8) **Max heart rate:** Maximum heart rate is almost equivalent to heart rate although it would help us to observe the heart condition throughout the day.

Future design and implementation using IoT devices:

9) **Exercise included angina:** Angina is a type of chest pain that causes due to the lack of oxygen flow to the heart. It is a symptom of Coronary heart disease.
10) **Old peak:** ST depression induced by exercise relative to rest which is measured by the vertical distance between the iso-electric line and the patient's trace.
11) **Slope:** The slope of the peak exercise ST segment which is a predictive value of coronary disease.
12) **CA:** A number of major vessels colored by fluoroscope which is a predictive value within 0 to 3.

According to the study, these 12 parameters are adequate enough to calculate and predict the overall heart condition of a patient but due to some limitations, we are working on the first 8 parameters and leaving Exercise included angina, Old peak, Slope and CA for future work.

B. Overview of the Design

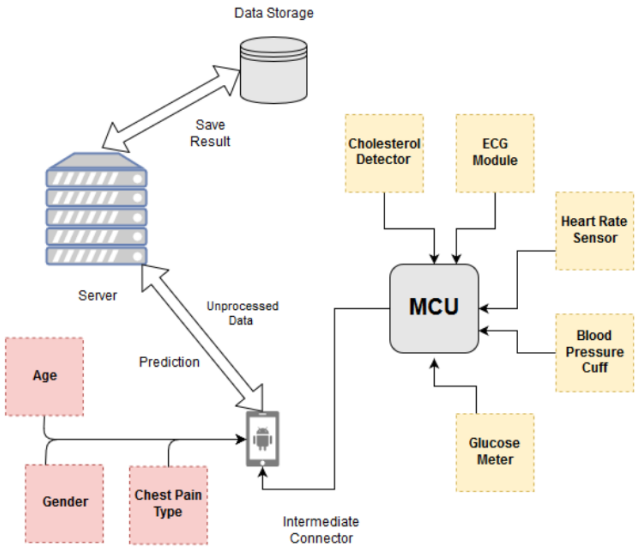

Fig. 1: Block diagram of combined prototype.

This is a simplified block diagram (Fig. 1) of the proposed prototype that we want to implement. We have proposed to use a Micro Controller Unit (MCU). The MCU will be connected to the required hardware sensors and modules. After acquiring all the data from the hardware components it will transmit the data to the smartphone via Bluetooth. The smartphone will also be used to collect the rest 3 parameters. Then all the 8 parameters will be combined and sent to the cloud running the Machine Learning algorithm which will provide the output to the user.

C. Prototype

1) Heart Rate Sensor Module

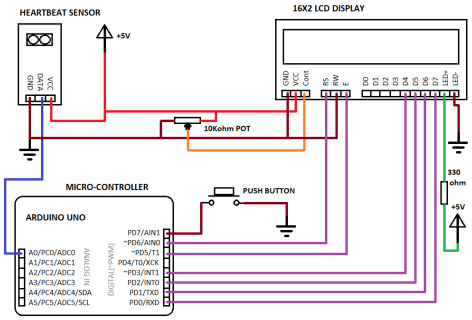

Fig. 2: Circuit diagram of heart rate sensor module.

We have implemented the heartbeat sensor to get the maximum heart rate of a patient. The circuit implementation (Fig. 2) is given which provides us the data of heartbeat of the subject. Heart Rate Module (LM358), Arduino UNO and LCD display are some of the components which have been used in this implementation.

2) ECG Module

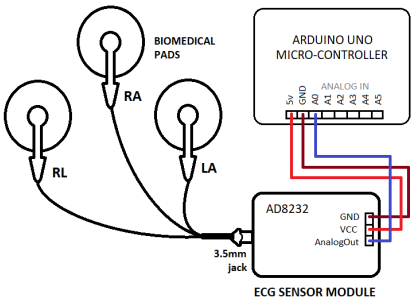

Fig. 3: Circuit diagram of ECG module (AD8232).

We have worked on patient Resting ECG where we used ECG sensor module - AD8232 to get ECG graph and corresponding data. We implemented the module with the existing Arduino UNO micro-controller as it has available peripherals which are required to implement that module (Fig. 3). AD8232 is a single lead ECG module. The sensitive pads are attached to the left hand, right hand and right leg. The output pin of the module is connected to an analog pin of the micro-controller. The output is converted by Arduino then the value is observable in the serial monitor as well as the LCD display.

3) Cholesterol

The non-invasive cholesterol detector (Fig. 4) works by transmitting infrared along the skin of the subject and measuring the received signal reflected back. This circuit contains a photodiode which responses to the infrared light source and converts the optical power into electrical current. The electrical current is then converted into a voltage by using a load resistor which varies between 0-5 V [14].

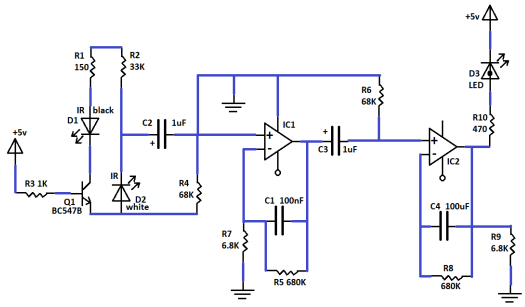

Fig. 4: Block diagram of Near-infrared sensor.

IV. Experimental Results

In this section, we have demonstrated our implemented circuits with the explanation of its working process and visualized the results we have received from different IoT devices.

A. Heart Rate Sensor Module

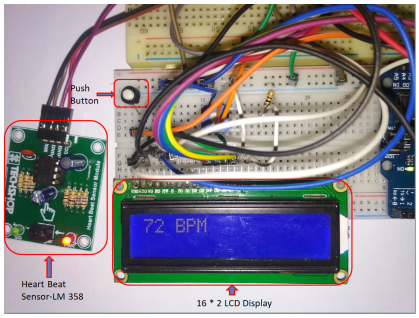

Fig. 5: Implementation of heart rate module sensor (LM358).

Here is the actual implementation of Heart Rate Sensor module (Fig. 5) which is connected to the MCU. The module measures the input for 10 seconds and provides the analog output to the Arduino which is then multiplied with 6 to get the Beats Per Minute (BPM) of the patient.

TABLE I: Sample data of heart rate sensor module

Subject No.	Beats Per Min	Physical Condition
1	66	Normal
2	72	Normal
3	62	Normal
4	90	Increased Respiratory Rate
5	110	Increased Respiratory Rate

Frequent changes in heart rate or regularity of pulse can signify the heart condition of a patient. So in our implemented module, the calculated Beats Per Minute (BPM) of a patient determines whether the physical condition of the patient is normal or the respiratory rate is high. See the table (Table I) providing some sample data of our module for more details.

B. ECG Module

Fig. 6: Output of ECG Module (AD8232).

A single lead ECG module is used which uses 3 electrodes to measure the electrocardiogram. At first, we connected the output pin to an oscilloscope where we found a signal. We have compared our received signal with real ECG signal by studying a paper [15] where we have found some similarities. Then we also visualized the output in the serial plotter where the output waveform was very promising. The main complex part of an ECG signal is the QRS complex (peak value), Q segment and S segment which we have found in our signal output. Still, there are a lot of issues with the ECG signal output on which we are working to improve and find out a much better result.

C. Cholesterol

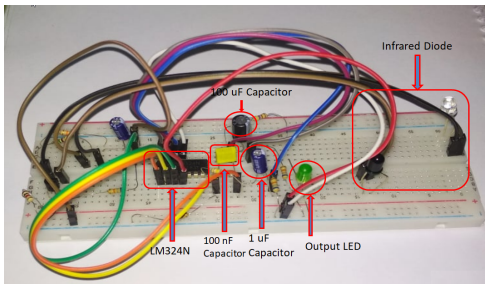

Fig. 7: Circuit diagram of near-infrared sensor.

The near-infrared sensor (Fig. 7) sends a signal through the human body and measures cholesterol without taking blood samples [14]. In the basis of each second, we are continuing the detection process for 30 seconds with 30 different samples taken on each of the seconds. Afterward, we are taking the average value of the voltage drop along the output terminal. We are taking 5.2 mm/L as the standard value of cholesterol in a healthy person.

$$\text{Correction Factor (X)} = 5.2 \,/\, \text{Voltage Drop}$$

(For standard value the Correction Factor is = 9.11)

Finally, we tuned all the output with respect to the value of (X). Which provided us the values similar to expectation. Further study and research are needed in this process.

TABLE II: Sample data of cholesterol in near-infrared sensor

Subject No.	Result	Reference	High
1	4.46		
2	4.56		
3	6.65	4-5 mm/L	>6 mm/L
4	5.10		
5	4.74		

According to the National Cholesterol Education Program (NCEP), a total cholesterol level of 4-5.17 mmol/L is considered normal and greater than 6 mmol/L is considered high. After testing our implemented module on 5 different subjects we found some data. The table (Table II) shows our findings compared to the biological reference.

D. Combined Prototype: Heart Rate and ECG

The H/W implementation (Fig. 8) we did so far is the combination of Heart Rate Sensor module and AD8232 ECG module where both modules work with a single Arduino UNO microcontroller using 9V DC battery. The required components are given below:

- Arduino UNO x 1
- 16 x 2 LCD Display x 1
- 10K Potentiometer
- 330 Resistor (Optional for LCD back light)
- Push Button
- Heartbeat Sensor Module with Probe (finger based)
- Mini Breadboard
- AD8232 ECG module
- 9V DC battery

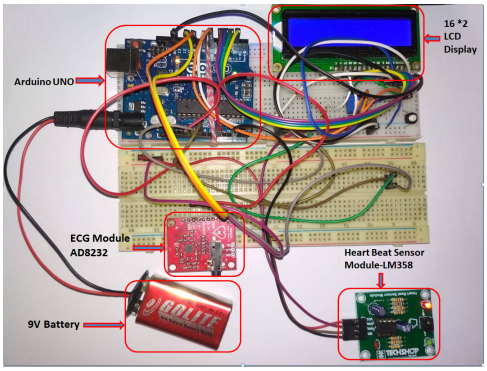

Fig. 8: Combined prototype of Heartbeat sensor module and ECG module.

E. Mobile Application

We have an application (Fig. 9) that is designed to control the complete hardware module. The application is designed for an android platform supporting from android 4.2 to upward versions.

At first, Bluetooth communication has to be made between the hardware module and application. From there we have

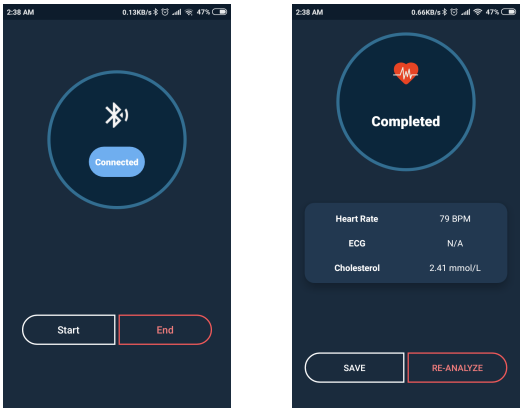

Fig. 9: Sample screen-shots from mobile application

to start the measurement procedure. When the start button is pressed, initially the heartbeat module will be activated and it will calculate the heart rate of a patient for 10 seconds. The final result will be saved for further usage. Secondly, the cholesterol module will start working. Finally, the data generated from the cholesterol module and heart rate module will be combined together and sent to the mobile application and the user will be able to see the final output. Then the user can choose to send the overall output to a cloud-based server where it will be saved in a database for further observation in a sequential way. The ECG module is yet to be connected to be operated from the mobile application.

V. Conclusion and Future Work

In this work, we have proposed a method to collect 8 parameters from the human body that are related to the heart using IoT devices to predict and prevent different severe cardiac diseases. The output of heart rate and cholesterol are quite satisfactory, however, there is still a lot of room to improve the results.

During the implementation phase, we have faced some difficulties. It was challenging to find the actual IoT devices for the implementation of our required parameters because of the lack of supplies in our country. While implementing the near-infrared sensor to collect cholesterol from the human body, receiving the input through a photodiode was tough. After putting much effort, we come up with an electrical current received by the photodiode and converted it into voltage. We tried our device on some subjects and after comparing with the real cholesterol values, we managed to find out the final results of the cholesterol of a patient. Getting the ECG signal from the human body was another challenge. The outputs that we were getting at first were not compatible with our needs. As a result, the ECG output signal was very different from the actual one. Finally, we used oscilloscope which provided us the output signal which was very similar to the actual signal. Also changing the module provided us with a satisfying result. Besides placing the electrodes correctly was quite challenging because it was not obvious which spot would provide the most accurate signal.

In future, we plan to combine all of our modules and circuits to build a complete prototype where after collecting the data, the data will be transferred to a server that runs a machine learning algorithm to predict the current cardiac status. The final results are to be visualized through a mobile application.

***Abstract*—The lack of credibility of data acquired through traditional means from a conventional metering system has reduced the efficacy of the energy management system. For overcoming the drawbacks of the conventional metering system, this paper proposes a smart IoT based energy management system (EMS), which not only ensures transparency and credibility of data but also offers flexibility to the consumers by offering the facility of remotely controlling their home appliances. Electricity consumption and its corresponding cost is calculated automatically and then the data is sent to a server in a periodic manner. For carrying out the task, NodeMCU has been utilized, which has the combined functionality of both microcontroller and Wi-Fi modules. By means of its microcontroller function, constant readings of energy meter are collected and saved in NodeMCU; then the data is transferred to a remote server on the internet via Wi-Fi. Consumers can observe real-time data on the server to gain a clear idea of electricity usage, therefore, they can reduce or increase the consumption as per their budget. This proposed system also provides the functionality of controlling the home appliances remotely over the Internet. Furthermore, electricity suppliers can produce bills from the server data automatically, making it a feasible solution. This paper also proposes and analyzes individual sub-metering of home appliances of high rating to observe and control their energy consumption. A detailed cost analysis of the system has been performed for ensuring its cost-effectiveness. According to the analysis, the total cost associated with the system is BDT 1064, which is fairly economical compared with existing systems. The add-ons of this proposed system can be also integrated with the existing prepaid meters of the market, eradicating its major drawbacks by providing added functionality.**

Keywords— IoT, Smart meter, Energy management, Home automation, Residential tariff.

I. INTRODUCTION

Bangladesh being a developing country, the energy demand is increasing by leaps and bounds. In order to meet with this rising energy demand, there has been a prolific increase in the implementation of alternative energy sources for generating more electricity, however, this is proving to be insufficient due to system energy loss. Therefore, a smart energy management system (SEMS) is necessary to ensure proper electrical power management, which will reduce the system energy losses. Furthermore, the integration of the SEMS with the internet enables the consumers to observe their consumption of electricity and take action according to their budget by remotely controlling the electrical equipment. It also provides a feasible mean to the electric suppliers for producing bills with minimal error.

With the advancement of technology, the accessibility of the internet is increasing day by day. Apart from being used for communication and entertainment purposes, the internet also provides a bunch of scopes in power system management, development, control, etc. Internet of things (IoT) is a cutting-edge technology that interconnects the 'things' over the internet [1]. These ‘things’ incorporate everything we can perceive of connecting-goods, buildings, appliances, machines, vehicles, plants, animals, and even human beings. It is estimated that the number of objects connected to the internet will reach 50 billion by 2020 [2]. IoT is a bidirectional approach, where objects export data to a distant server and the users can control the objects through the server by software programs and it is mainly done over Wi-Fi networks. The traditional electric power network has many limitations, however, by integrating with IoT it can be transformed into an intelligent power network [3]. The application of IoT can effectively improve the accuracy of real-time monitoring and control of smart grid [4, 5]. The informatization of power grid system can be sped up by utilizing IoT and thus is beneficial for effective management of the power grid infrastructure [6]. It can also be used for precise and accurate estimation of energy consumption [7]. Recent studies show that IoT can also be integrated with smart energy meters and can increase their accuracy [8-10]. IoT based smart energy meter has been proposed in [11-13]. However, it does not have the functionality of remotely controlling the home appliances. An efficient billing system can also be developed using IoT [14, 15]. It also possesses great potentiality in its application in the control system of smart homes [16-18].

This paper proposes a SEMS based on IoT, which ensures the credibility of smart meter data as well as provides the facility for controlling home electrical appliances remotely. The energy usage data of the consumer is stored in NodeMCU, which is then transferred to a remote server on the internet using Wi-Fi. NodeMCU is an open-source development kit composed of microcontroller and ESP8266 Wi-Fi module, where microcontroller part does the necessary calculations and control and ESP8266 helps in communication over Wi-Fi. The corresponding cost of the

consumed electricity is automatically updated, reducing the errors that occur in the conventional energy meter system. This proposed method also reduces the complexity of bill payment and the consumer can check his/her energy usage at any time. Furthermore, it gives consumers the ability to remotely control any home appliance. Hardware implementation of the system along with necessary software configuration has been carried out in this research. Additionally, a comparative cost analysis with the existing energy meters available in the market has also been shown in this paper.

The remaining part of the paper is organized as follows: in section II, the present condition of energy metering system in Bangladesh is represented. The tools and apparatus required for the proposed system and its working principle are discussed in section III. The problems that occur during the operation of the proposed smart energy meter and corresponding solutions are presented in section IV, which is followed by a cost analysis in section V. Finally, in section VI, the key features along with future scope are described as a conclusion.

II. Present Condition of Energy Metering System in Bangladesh

A common practice in Bangladesh is that a person from utility services goes to individual consumers to collect the energy meter data. The bill is prepared using those data and the bill paper, which contains all the information about the usage of electricity in that month, is sent to individual consumers for payment. Finally, consumers pay their bill according to the bill paper, which was sent to them by going to a particular station or a bank. Therefore, this process is very much hassling and requires a lot of time and steps, and since there is direct involvement of human in collecting the meter data, the credibility of this system is compromised.

There are system losses occurring in the power network due to technical and non-technical aspects [19, 20]. Technical reasons include losses in power generation equipment, transmission lines, distribution lines, etc.; whereas non-technical losses occur mainly due to customer level meter tampering. In order to reduce the losses occurring at the customer level, the prepaid meter has been introduced in some cities and the rest are on the way. Although the prepaid metering system offers more advantages than the conventional meter system, it also has some major drawbacks. The customers need to purchase a card to refill the account but purchasing the card is quite troublesome sometimes. The consumers also need to predict the monthly bill and recharge accordingly, which can create a situation of uncertainty. Furthermore, prepaid energy meters do not provide the consumer with the ability to control electrical appliances remotely.

III. IoT Based Smart Energy Meter

IoT-based smart energy meter solves the issues of prepaid energy metering by minimizing the complexities and mitigates the non-technical losses by ensuring the credibility of data. It also brings new important features, such as real-time viewing of consumption data and remote controlling of home appliances. A single phase static watt-hour meter is used to calculate the consumed energy and these data are extracted from the meter through a LED. Table 1 shows the specification of the watt meter used in this paper.

TABLE I. Specification of The Single Phase Static Watt Hour Meter

Supply System	Range
Voltage	0 to 240V (Phase to neutral)
Current	5A to 30 A
Frequency	50Hz ± 5%
Temperature	$-10°C\ to\ 50°C$

In order to perform IoT operation, a microcontroller along with Wi-Fi module is needed. The microcontroller sends the data to predefined internet server using Wi-Fi. NodeMCU is such a development board that provides combining the functionality of having both I/O ports like microcontroller and Wi-Fi module. This kit is based on the ESP8266 Wi-Fi module. It is programmed in an Arduino environment. Here, the microcontroller does all the calculations necessary, whereas ESP8266 provides the functionality of communication via Wi-Fi. The pin diagram of the NodeMCU is shown in Fig. 1.

Another required apparatus for the proposed system is the optocoupler, which provides isolation between relatively high voltage energy meter side and low voltage microcontroller circuit. The electrical signal from two isolated circuits is transferred using an optocoupler. Data from power circuit is fed to optocoupler and then microcontroller extracts the data from the optocoupler. The model used in this work is optocoupler – 4N25. Other components used for the proposed IoT-based smart energy meter are a 220V – 9V transformer to step down the supply voltage, IC 7805 to regulate dc voltage, diodes for rectification purpose, capacitors for smoothing the rectified dc, and some light emitting diodes (LED) to emulate the home appliances.

Fig. 2 shows the functional block diagram of the whole system. In the functional block diagram of a conventional meter, only the ac power supply, energy meter, and loads block exist. However, some additional blocks are needed to be added here to realize the IoT and energy management features. The energy consumption data is taken from the energy meter through the optocoupler. There is a LED in the energy meter named 'Cal', which blinks a certain fixed times per Kilo Watt

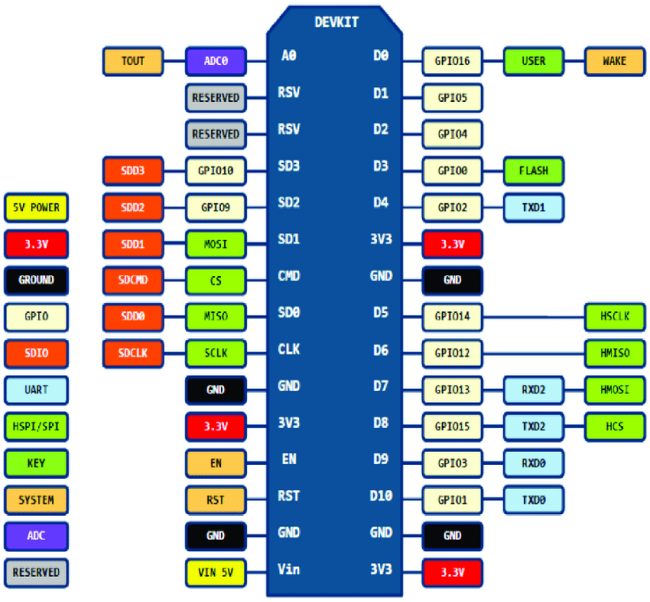

Fig. 1. Pin diagram of NodeMCU.

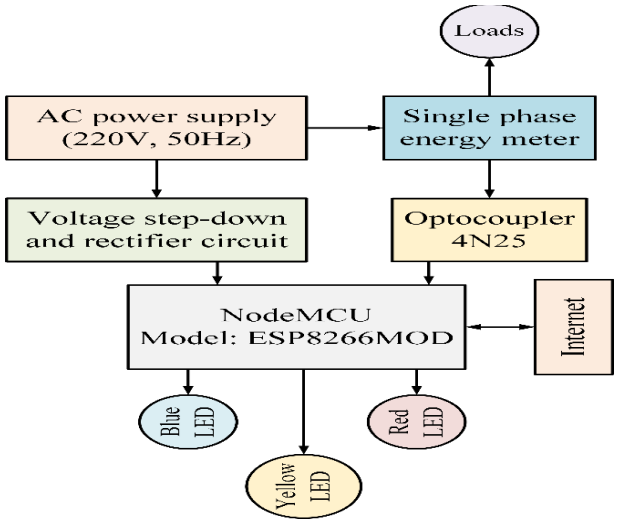

Fig. 2. Block diagram of the IoT based smart energy management.

Hour (kWh) for a particular energy meter. The meter used in this project has such a functionality, where the 'Cal' LED blinks 3200 times per kWh. This LED data is then fed to a microcontroller through the optocoupler. The number of blinking is observed by microcontroller programming and by using this data, the total electricity units consumed and associated cost are calculated.

The main feature of this system is to collect data over the internet. Therefore, the consumed unit of electricity and associated cost data need to be transmitted over the internet. This is done by writing the required Arduino code in the NodeMCU. In order to practically implement this system, NodeMCU needs internet connectivity and to store data on the internet, hence, a website domain is needed. However, in this prototype, the website is hosted locally and Wi-Fi hotspot connection is given to the NodeMCU to simulate the prototype. The Wi-Fi service set identifier (SSID) and password are written in the Arduino script. Therefore, NodeMCU gets connected to local Wi-Fi whenever Wi-Fi is available. The updated data are transmitted at a certain time interval.

The power supply of NodeMCU is taken from the main AC power supply. In order to use the 220V AC supply as 5V DC supply, voltage step down transformer and a rectifier circuit are used, which is shown in Fig. 3. In this circuitry, a step-down transformer is used to convert 220V AC to 9V AC. This 9V AC is then transformed into 9V DC by a full bridge rectifier circuit. The DC produced in the output of full bridge rectifier has a significant amount of ripples and in order to

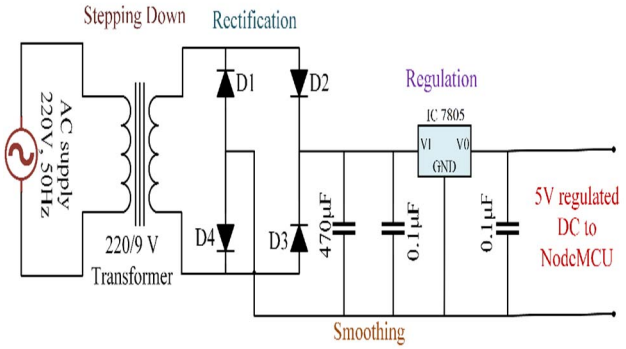

Fig. 3. Rectifier circuit to convert 220V AC to 5V DC.

reduce it, a smoothing capacitor is used in parallel. Finally, this 9V DC is transformed into 5V DC by using the 7805 regulator IC that is fed to the NodeMCU. The hardware implementation of the prototype is shown in Fig. 4.

Another important feature of this system is the control of home appliances over the Internet. A user of this proposed system can check the status of his home appliances and can take any action as he wants; that means he can turn on or off any home appliance remotely using the internet. In order to simulate this, three LED's are connected to NodeMCU and can be controlled over the Internet. The LEDs are connected to the general purpose input/output (GPIO) pins. Some predefined commands have been configured in the Arduino script to make the LED either on or off. When those commands are transmitted to the NodeMCU from the website, the LEDs will respond according to the specified commands and thus, they can be controlled easily. In real life application, this feature can be implemented by using a relay circuit. By controlling the relay, electrical appliances like fan, light etc. can be turned on or off as required.

When a user logs in to his account, he will see a webpage, which is shown in Fig. 5. This webpage has been developed using the basic HTML and bootstrap library which are open-source resources. Consumed unit of electricity and associated cost are shown on the webpage. The consumer can remotely

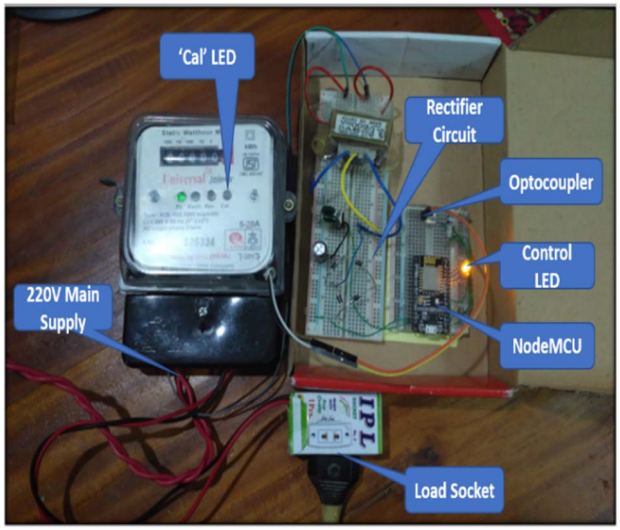

Fig. 4. Hardware implementation of the prototype of IoT based smart energy management system.

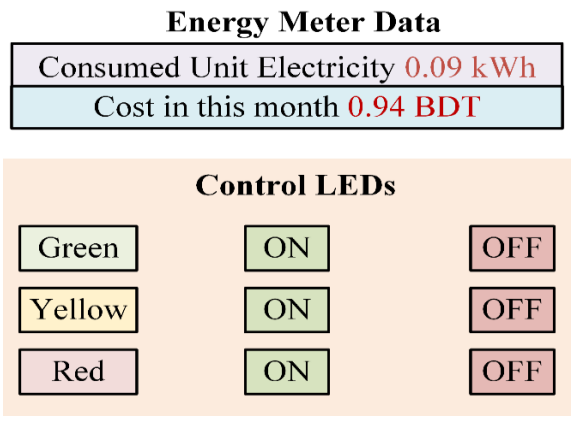

Fig. 5. Webpage showing the consumed electricity and their associated cost along with the feature of controlling the appliances remotely.

control any home appliance using this webpage. For this instance, in order to control the green, yellow, and red LEDs over the Internet, two buttons have been configured as ON or OFF for each LED and they can be turned on or off individually just by clicking on the corresponding buttons. A comparative analysis of the proposed system with existing works is tabulated in table II. The proposed system does not require any additional microcontroller as the NodeMCU has the dual functionality of microcontroller and a Wi-Fi module. Furthermore, the proposed system also has the feature of controlling home appliance remotely.

TABLE II. COMPARISON OF PROPOSED METHOD WITH EXISTING WORKS

Authors	**Microcontroller**	**Optocoupler**	**Functionality of controlling of home appliance remotely**
Abate *et al.* [11]	STM32F205RB	Not used	Not available
Sahani *et al.* [12]	ATMega328	MOC3071	Not available
Singh *et al.* [13]	ATMega328 and PIC16F877P	Not used	Not available
Proposed	Built-in microcontroller in NodeMCU	4N25	Available

The proposed system has been designed to determine the electricity consumption and calculate the corresponding cost for residential consumers only. Let us consider b is number of blinks of the 'Cal' LED in a month. As the 'Cal' LED blinks 3200 times per kWh, the total energy consumption (kWh) is

$$a = \frac{b}{3200} \quad (1)$$

If s and d are the service charge and demand charge per month in Bangladeshi Taka (BDT), respectively, then the associated cost of that month c can be calculated using the following equation

$$c = (a \times k) + s + d \quad (2)$$

Here, k is per unit price of energy in (BDT), whose value depends on a. According to Dhaka Power Distribution Company (DPDC), the value of k for different consumed unit (a) is shown in table III [21].

TABLE III. TARIFF RATE FOR RESIDENTIAL CONSUMERS

Consumed Unit (a)	**Per Unit Rate of Energy (k)**
0-75	3.80 BDT
76-200	5.14 BDT
201-300	5.36 BDT
301-400	5.63 BDT
401-600	8.70 BDT
601-above	9.98 BDT

The existing tariff rates in Bangladesh for different categories according to DPDC [21], is shown in Fig. 6. The variation of service charge s and demand charge according to DPDC [20] is presented in Figure 7.

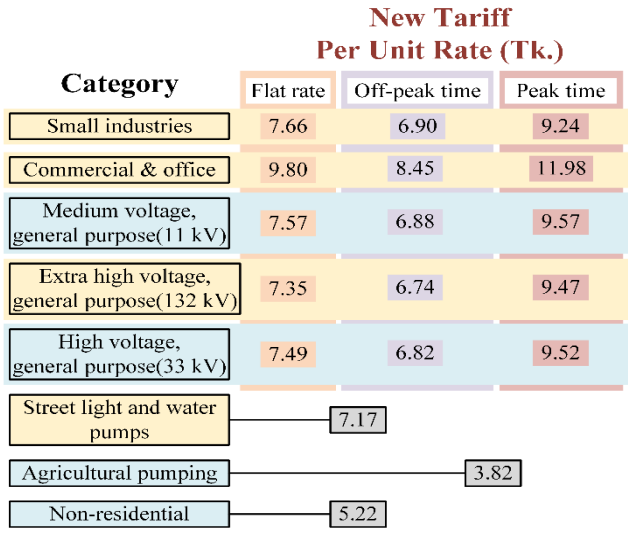

Fig. 6. Existing tariff rates in Bangladesh [21].

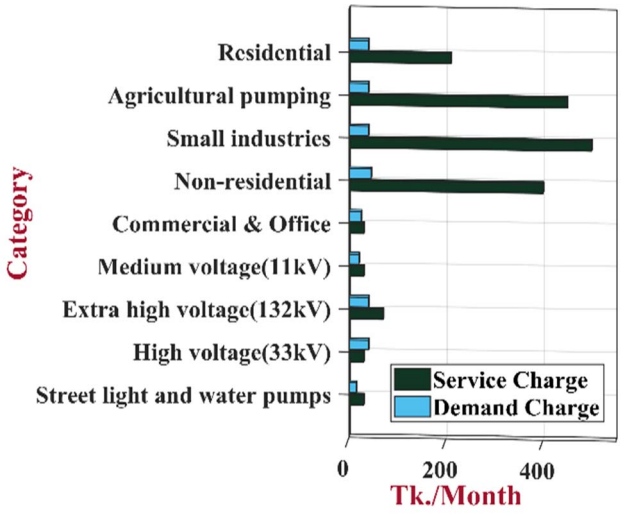

Fig. 7. Variation of demand charges and service charges in Bangladesh [21].

IV. PROBLEMS AND SOLUTION

NodeMCU needs power from the main supply to operate; thus when power interruptions occur, it will be turned off. However, there is no possibility of data loss as the data is stored periodically in the internal memory of the NodeMCU. Each time the NodeMCU starts, it extracts the most recently updated data from the memory. This system needs an Internet connection to send data to the web server and there might be the possibility of having no internet connection at a certain time. However, this problem is solved as NodeMCU sends the updated data whenever it regains internet connectivity. Data are always updated and stored in the internal memory of NodeMCU and is sent to the server whenever the internet is available. Therefore, there is no possibility of data loss. The exchange of data over the public domain such as the Internet is very much susceptible to unauthorized access [22]. Therefore, the system will be synchronized to a distant server and it can be programmed so that any undesirable attempt will

inform the consumer as well as the electricity provider. In this way, the risk of data theft can be reduced to a minimum.

V. Cost Analysis

There are various types of energy meters available in the market, their price ranging from BDT 2000 to 10000. Different prepaid energy meters available in the market and their corresponding prices are shown in table IV.

TABLE IV. Price of Available Prepaid Meters In Market

Product Title	Market Price
Liberty Prepaid Energy Meter	BDT 9880
Techno Prepaid Energy Meter Class 1.0	BDT 5070
Elmeasure Prepaid Energy Meter	BDT 5000
Meter by Yueqing Haixin Electronic Company	BDT 2540

Cost of different equipment required for the proposed system and the overall cost is shown in Table V. In our proposed design we used the Universal Energy Meter which is a conventional energy meter. Additional equipment such as, NodeMCU, optocoupler, and voltage step down circuitry are used as add-ons so that this conventional energy meter can function as IoT based smart energy meter. Furthermore, it has the facility to provide the consumers the ability to control their home appliance remotely. The aforementioned add-ons are also compatible with the existing prepaid meters available in the market. Therefore, the consumers are able to pay their bills without having to predict their monthly consumption of electricity with the added facility of remotely controlling their home appliance. From data presented in table III and IV, it can be said as the add-ons cost is very cheap, therefore, it is very much cost-effective integrate them with conventional or prepaid energy meters.

TABLE V. Costing of Different Equipments of The IoT Based Energy Mangement System

Equipment		Market Price
Universal Energy Meter		BDT 430
Add-ons	NodeMCU V-3 Development Kit	BDT 500
	4N25 Photo Transistor Optocoupler	BDT 15
	Voltage Step Down Circuitry	BDT 120
Total		**BDT 1065**

VI. Conclusion

In this paper, integration of IoT with energy management system has been demonstrated to make a more effective and reliable system compared with the conventional energy management system. Instead of collecting data from door to door, the key feature of the proposed system offers a more accessible way of collecting data from a server through internet, which is automatically updated after a short time interval via Wi-Fi. The NodeMCU used in this system has the dual functionality of a microcontroller and a Wi-Fi module, which eliminates the need for an additional microcontroller. Furthermore, remote control of domestic appliances has also been made possible through this system. The total hardware implementation along with interfacing with the internet has been presented in detail. For ensuring the cost effectiveness, a detailed cost analysis has been conducted. The overall cost of the proposed IoT based smart energy management system is BDT 1065 and add-ons cost is BDT 635. Hence, the proposed system is cost effective and the add-ons can be also integrated with the existing prepaid meters, which can expunge its major drawbacks by providing added functionality. Therefore, the presented design in this paper, possesses high potentiality in its application in energy metering system of Bangladesh.

***Abstract*—Sudden and unexpected death due to heart failure is a major cause of mortality among middle aged and elderly people. An efficient heart monitoring system can find out the malformation of heart conditions and that can also be helpful in diagnose at critical ambience. Sometimes the distance between patients and doctors is the main barrier that people do not have access to quality health services and thus having trouble for their regular health examine. IoT-based healthcare monitoring system is one of the manifested application areas in medical science. As a significant access in diagnose heart disease ECG observing system is widely used. In this paper, a progressive method for ECG monitoring system based on Internet of Things (IoT) has been proposed. In this study, a system is designed to frequently monitor the Electrocardiogram (ECG) signal collected from patient's body using wearable sensors and the data is stored into the database which can be accessed by authorized personnel only. When any malformation is found an automatic email is sent to the users and doctors for analyzing about the critical conditions of the patients and provides emergency health assistances. In order to verify the authenticity of this system tests have been implemented on several patients and the report shows that, this system is dependable and efficient for collecting real time ECG data which can be very helpful in diagnose heart diseases. This IoT-based low cost device can be reliably used to reduce the risk of disability and mortality rate due to cardiovascular diseases.**

Keywords—Internet of Things (IoT), Smart Healthcare, ECG Module, IoT Cloud, Graphical User Interface (GUI).

I. INTRODUCTION

The Internet of Things (IoT) has many purposes in medical areas such as distant patient monitoring, dietary program, testimony of chronic diseases, elderly people care etc. The elderly population is rising continually both in rural and urban areas, so observing their health regularly with the desire of staying at home and at low cost is one of the basic appeal. Healthcare personnel can assess, diagnose and prescribe elderly people by gathering medical information from remote regions by using IoT. The significant part of IoT can be used in so many medical equipment, sensors and imaging devices to primarily determine the patient's health statuses and to deliver them proper care in a shortest possible time. IoT-based healthcare services can be implemented at low cost hereby maximizing the user contentment. Thus, the main purpose of IoT-based healthcare system is its cost effectiveness and secures interconnection for individuals, clinics and different healthcare institutions.

Health conditions of aged people needed to be checked in regular basis which is a greater challenge both in medical research and hospitals [1].In medical institutes or hospitals, conventional 12 leads systems are used to collect ECG signals from patient's body. This device is too expensive to use at home or personal use and cannot be used as portable. It takes huge amount of time for routine checkup during each visit to hospitals and manual recording can also cause human made error. In such a manner, a low cost portable system for continuous ECG monitoring is highly required. Most of the available ECG monitoring devices use smart phones for secondary data processing [2]. The uses of smart phones in data transfer and processing have great consequences on regular use due to its limitations of power and computational effectiveness.

In our study, a wearable ECG monitoring system has been proposed and implemented occupying Internet of Things (IoT). This customized device can directly sent ECG data collected from patient's body to IoT cloud using *Wi-Fi*. *Wi-Fi* has wider coverage areas and higher data transfer rate than Bluetooth or ZigBee. The whole work is done by connecting Raspberry Pi with internet. Here, ECG sensor AD8232 has been used for ECG monitoring. Data have been processed in Raspberry Pi which uses processing software and a band pass filter is used for eliminating different noises to form an electrocardiogram (ECG) graph. An automatic email will be sent to the users and authorized doctors in case of abnormalities found in patient's body. This device is hazard free and cost effective for the remote patients as they do not need to visit the doctors regularly. We have compared our customized device with standard 12 lead ECG modular in generating heart rates and waveforms and the result shows that, our system can be used reliably.

The rest of the paper is organized in following sections. In section II, background and related works is discussed. In section III, system architecture of IoT based ECG monitoring system has been proposed and being explained. In section IV, shows the flowchart and implementation of IoT based ECG monitoring system. We conduct several tests on patients in order to verify the reliability of the system and it is discussed as experimental results and analysis in section finally we conclude the paper in section VI and also

discussed about the future scopes in the field of medical science using Internet of Things (IoT).

II. Background and Related Works

Internet of Things (IoT) has come into view as an important technology for health monitoring system. In professional medical institute ECG data is collected employing 12 electrodes due to their good performance in short term calibrating. But these devices are unlikely to be portable and patients often have to visit medical institutes for regular checkup which is also very expensive. Thus, there is a great demand in the domain of health care to support elderly people to care at home. So we have recommended allow cost ECG monitoring system and implement it so the elderly people can get precise care without travelling the hospitals frequently.

Spine, Pascoli, Iannaccone,et al. developed a low power wearable ECG monitoring system for multiple patient remote monitoring [3].The authors developed low-power ECG monitoring system with a wearable facility ZigBee protocol for data transfer from sensor but there was no real time notification in this system. Sneha and others [4] proposed an architectural framework using mobile to monitor the ECG of cardiac patients. The main drawback of the system was it cannot be controlled without a mobile application. But our device can be controlled by IoT.

An integrated wireless system was proposed for heart failure patients who can detect ECG signal, Heart Rate Variability (HRV) continuously using software based algorithm [1]. IoT can be used in identifying human diseases, since heart failure is a major problem now-a – days; ECG monitoring is necessary both in homes and hospitals [5]. In hospitals ECG data is collected using 12 electrodes. Basically the ECG instrument measures the difference in voltage potential between each of the electrodes. In medical equipment which consist 12 electrodes waveforms only 8 waveforms can be measured and rest of the 4 is extrapolated by measured waveforms. The equipment which is used in hospitals is not portable and also expensive for regularly use in home. So patients need to go to hospitals for their regular checkup. A low cost ECG monitoring system for home and hospital uses is highly needed. A low power mixed signal SOC for portable ECG monitoring using Bluetooth protocol has been introduced. This system is portable because electrodes are usually less than traditional methods [6].

Electrocardiography (ECG) for heart disease using medical e-services patients is a crying need for development countries. Because in traditional ECG monitoring process the collected data is saved and simultaneously sent to the doctors for further analysis. It might cause delay in emergency time and sudden heart failure cannot be detected from this system. In this paper sensor based system architecture is proposed for ECG monitoring based on Internet of Things. Finally based on the architecture we design an ECG based heart rate monitoring system .The collected ECG data will be directly sent to the database server using ***Wi-Fi*** module. ***Wi-Fi*** has been used here because it can provide larger cover areas and higher data rates. Wi-Fi is used here that it can send email to the doctors or relatives in case of patient's emergency health conditions. The proposed system is successfully developed and tested to examine the effectiveness and reliability of the system. This is a low cost smart device which can be used for patient's health monitoring so that doctors can take precautions at proper time to avoid sudden death due to cardiovascular diseases.

III. System Architecture of IOT Based ECG Monitoring System

The architecture of the IoT-based ECG monitoring system is illustrated in "Fig.1", which mainly consists of three parts, i.e., the ECG sensing network, IoT cloud, and GUI. The components used in ECG Sensing network are: ECG AD8232 Sensor, Raspberry Pi Model 2, and Arduino Uno.

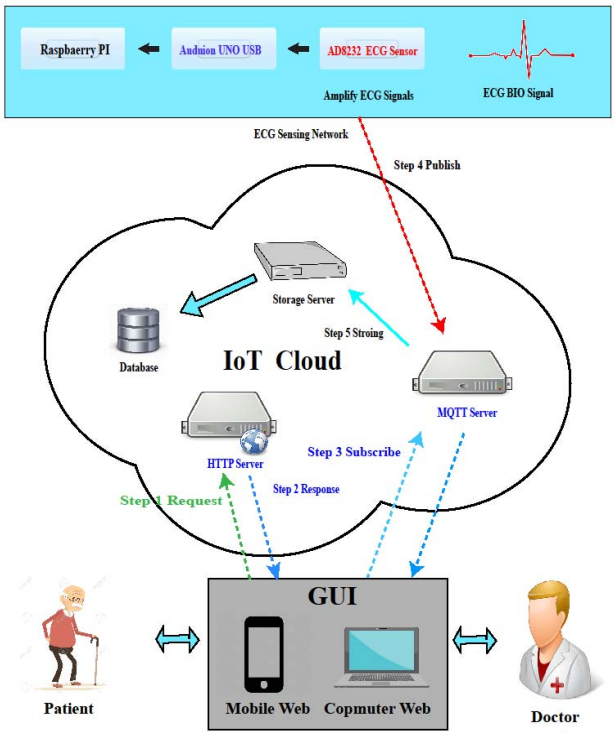

Fig. 1 Proposed Architecture of the IoT-based ECG monitoring systems.

A. ECG Sensing Network: ECG sensing network is set for assembling physiological data from the body surface and pass on these data to IoT cloud through a wireless channel. In our equipment wearable ECG sensor has used to gather data from patients body over long hours. Then the ECG signals are processed through amplification and filtering etc. to improve the signal quality. The ECG data gathered from sensors are transmitted to the IoT cloud via a specific wireless protocol such as Bluetooth, ***Wi-Fi***, ZigBee etc. [7]. With satisfying energy consumption all these three protocols can transfer enough data rates for transmitting ECG signals. Moreover, due to limited communication

ranges of Bluetooth and ZigBee,***Wi-Fi*** is used in our proposed system .Comparisons among various types of ECG sensing networks are given in Table I.

TABLE I.
COMPARISONS AMONG TYPICAL ECG SENSING NETWORKS SUCH AS ***WI-FI***, BLUETOOTH AND ZIGBEE.

Standards	***Wi-Fi* based ECG sensing network**	**Bluetooth based ECG sensing network**	**ZigBee-based ECG sensing network**
Protocol	IEEE 802.11	IEEE 802.15.1	IEEE 802.15.4
Coverage	20-200 m	20-30 m	2-20 m
Data rates	11-54 Mbps	3-24 Mbps	10-250 kbps
Power consumption	Medium	Low	Low
Terminal dependency	Data collection is independent of smart terminals	Smart terminals are needed for receiving and forwarding sensed data.	Smart terminals are needed for receiving and forwarding sensed data.

I. Raspberry Pi: Raspberry Pi is a low cost, small sized, powerful minicomputer which can interface with many devices. Here we used Raspberry pi model-3b.In this system we use Raspbian operating system which is Linux based. ***Wi-Fi*** is a built in characteristics in Raspberry- Pi. So we need not to connect Wi-Fi module for data sending.

II. Arduino Uno: Arduino Uno is a microcontroller board on ATmega328P (datasheet). It is used in this system for detecting ECG signals from AD8232.

III. ECG Sensor: ECG sensor AD8232 shown in "Fig. 2" is used for collecting ECG data from human body by using electrodes on the patient's skin. We collected signals from human body via AD8232 using Arduino Uno; it sent the collected signals to raspberry pi. Raspberry pi then processed the signal by using Processing 3.0 and shows the image finally on display.

Fig. 2. AD8232 ECG Sensor

B. IoT Cloud: With the help of IoT cloud in ECG monitoring system we can store data, modify data and all the patients information's are saved here. It can also send disease warning and protecting patients from getting injured.

C. GUI: Graphical User Interface (GUI) is used for data imagination management. It contributes easy entry of the data in the IoT cloud. Users can log onto the cloud to acquire visualized ECG data in real time. Generally mobile applications and web pages are the two kinds of GUI's are available for users to visualize ECG data. Although mobile app can ensure immediate response but web pages are the best options in terms of protection and up-gradation.

IV. FLOWCHART AND IMPLEMENTATION OF IOT BASED ECG MONITORING SYSTEM

"Fig.3," shows the flow chart of our proposed system. At first the user switch 'on' the device and the device will check whether all the modular are 'on' or 'off'. If the modular is 'off' then the system will remain 'off'. Otherwise, when the modular is on so the system will run and start to collect data from human body. After that, these data will be saved automatically in local database, when internet connection is found it will be analyzed the data in cloud database and show results for abnormal condition and send it to the users via ***Wi-Fi***. The system proposed and implemented in this paper take ECG data from patients' body and at any case of abnormalities an email is sent to the doctors so that, they can take necessary initiatives to prevent damages due to cardiovascular diseases.

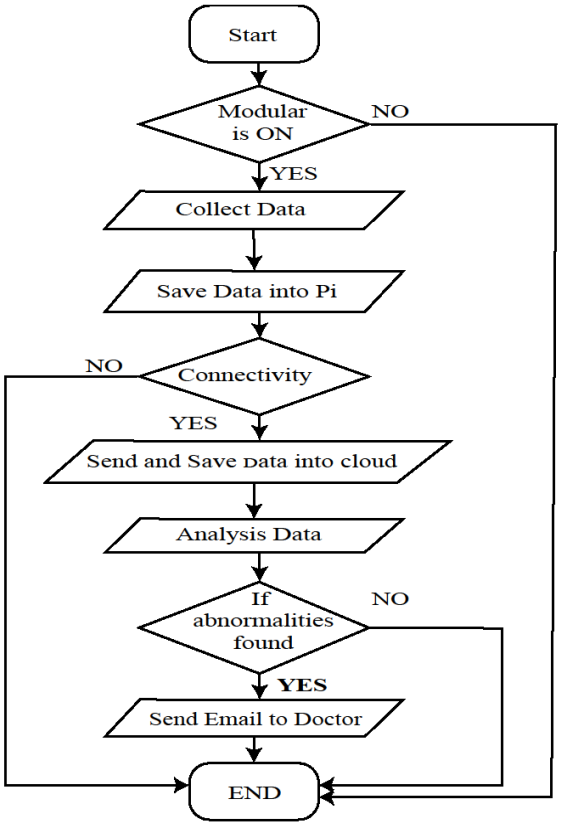

Fig. 3. Flowchart of the IoT -based ECG monitoring system

In medical institutes or hospitals conventional 12 leads systems are used to collect ECG signals from patient's body. This system cannot be used as portable. But for sudden analysis of patient's condition 3-lead system is

sufficient [8]. "Fig.4". shows the physical appearance of our ECG monitoring system using 3-lead system.

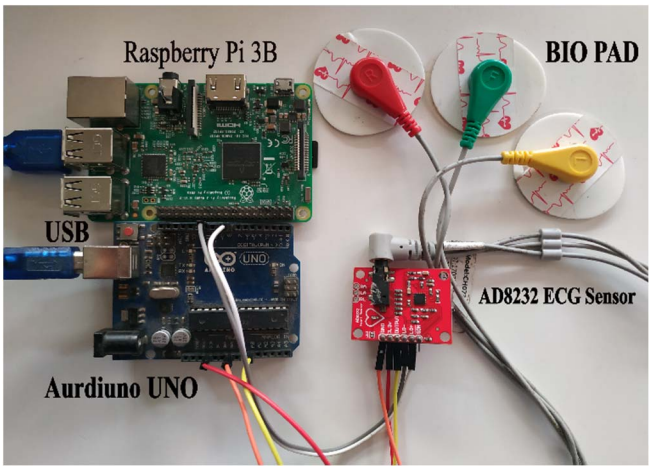

Fig. 4. Physical appearance of ECG monitoring system

IV. EXPERIMENTAL RESULTS AND ANALYSIS

A 3-lead placement is adequate to analysis the primary features of ECG signal [9] compared to conventional 12-lead ECG monitoring device used in hospitals. In order to best sample the ECG signal, the electrodes need to be placed around the heart and form a triangle. In order to justify the performance of our system we have conducted several tests on some patients.

Typical ECG signals mainly consist of five type of waves such as the P wave, T wave, Q wave, R wave, and S wave, as shown in "Fig. 5". The intervals of these waves are used to diagnose several of heart diseases.

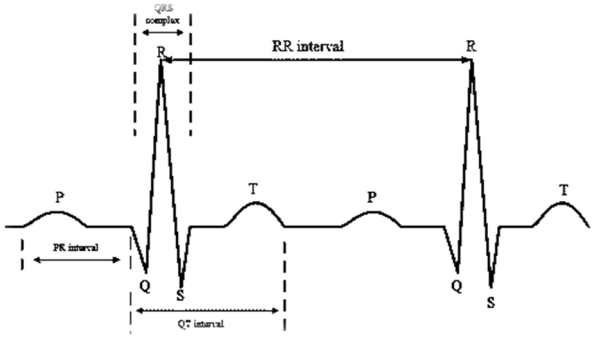

Fig. 5. Standard ECG Signal

- **RR** interval: As one of the most conspicuous characteristics, the R wave is often used to identify the period of an ECG signal. RR interval indicates the time interval between two adjacent R waves, which may become irregular in the event of some heart diseases, for example, the arrhythmia.
- **PR** interval: The PR interval measures the time between the beginning of the P wave and that of the QRS complex. It indicates the time the impulse takes to reach the ventricles from the sinus node.
- **QT** interval: QT interval represents the time between the start of the Q wave and the end of the T wave, which is related to the ventricular depolarization and repolarization. There is an increased risk of ventricular fibrillation or even sudden cardiac death if the QT interval exceeds the normal value.
- **QRS** complex: QRS complex is mainly associated with the Ventricular depolarization, which consists of three important waves, i.e., Q wave, R wave and S wave. By analyzing the QRS complex, certain diseases are likely to be detected such as drug toxicity and electrolyte imbalance.

According to [9] [10], the normal values of ECG parameters are listed in Table II.

TABLE II.
NORMAL VALUES OF KEY ECG PARAMETERS.

Features	Normal Range (Second)
RR Interval	0.6- 1
PR Interval	0.12- 0.20
QT Interval	0.32- 0.44
QRS Complex	< 0.12

Abnormalities are found when the two conditions are not valid. Finally, if any disorders are found then an emergency email has been sent to the users or doctors that, they can take emergency steps to prevent severe damage of the patients. This can reduce mortality rate and any kind of damages that causes due to heart failure.

To get the most proper data for sudden analysis of patient's condition 3 lead electrodes are placed in a triangular shape around the heart. "Fig.6", shows, the ECG data collected from a 40 years old healthy person. It is evident that the intervals between adjacent R waves (RR interval) are nearly the same, which shows no risk of developing arrhythmias.

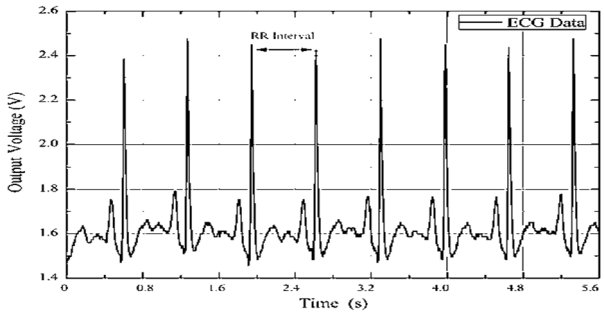

Fig. 6. Real time ECG signal of a healthy volunteer.

In order to analyze the key features of the measured ECG signal, two cycles of the signal are chosen as examples, which are shown in "Fig. 7".

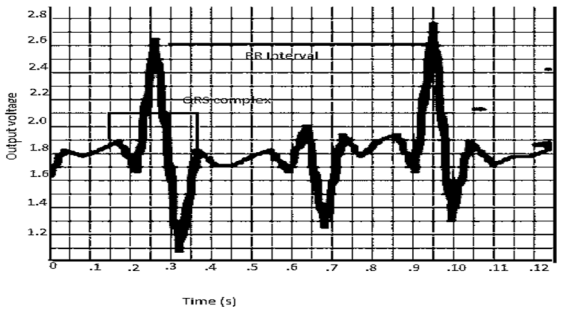

Fig. 7. Key features of the measured ECG signal.

In “Fig. 7”, it can be observed that, QRS complex is also regular indicating no abnormality in the processes of ventricular depolarization and repolarization. QT interval is also normal. Finally, the PR interval is also within the normal range, which implies that the process of atria depolarization is normal as well. So this person is not suffering from any heart diseases.

We have developed a prototype system and tested our device with a 12-lead ECG machine and the experimental result shows the reliability of our system

Percent Difference in “Equation (1)” is used to determine the relative difference between 12 lead and 3 lead portable ECG system.

$$\% \text{ difference} = \left| \frac{Expected - Actual}{\frac{Expected + Actual}{2}} \right| * 100\% \qquad (1)$$

Where, Expected = ECG value gained from 12-lead ECG machine and Actual = ECG value gained from ECG device prototype.

TABLE III.
SUMMARY OF PERCENT DIFFERENCE OF ECG PARAMETERS

ECG Parameter	Data of 12 lead ECG Device	Data of 3 lead ECG Prototype Device	Percentage Difference (%)
RR Interval	0.7709	0.7785	0.98
PR Interval	0.1232	0.1544	20.2
QT Interval	0.3496	0.3507	0.31
QRS Complex	0.0959	0.1040	8.104

From the Table III, we can observe that, the value of our prototype is quite similar with expected value collected from 12-lead ECG device.

To determine the efficiency rate of our device "Equation 2" is used to test the number of successful attempts vs. the total number of attempts.

$$\% \text{ reliability} = \left| \frac{number\ of\ successful\ attempts}{total\ number\ of\ attempts} \right| * 100\% \qquad (2)$$

We have tested our prototype device on 10 patients at the cardiology department of Delta Medical College and Hospital and we got 80% efficiency in detecting ECG conditions. From the samples collected from our prototype four trials (4, 8, 9, and 10) did not match with the 12-lead machine. The results have been shown below in Table IV.

TABLE IV.
TABULATED SUMMARY OF COMPARISON BETWEEN TWO DEVICES

Trial	Trial 12-lead ECG Device	Trial 3-lead ECG Device
1	Normal Sinus Rhythm	Normal Sinus Rhythm
2	Normal Sinus Rhythm	Normal Sinus Rhythm
3	Normal Sinus Rhythm	Normal Sinus Rhythm
4	Normal Sinus Rhythm	Sinus Bradycardia
5	Normal Sinus Rhythm	Normal Sinus Rhythm
6	Normal Sinus Rhythm	Normal Sinus Rhythm
7	Normal Sinus Rhythm	Normal Sinus Rhythm
8	Normal Sinus Rhythm	Sinus Bradycardia
9	Sinus Bradycardia	Normal Sinus Rhythm
10	Normal Sinus Rhythm	Sinus Tachycardia

V. CONCLUSION AND FUTUTRE WORKS

The implemented prototype of our IoT-based ECG monitoring system is highly efficient, low cost device and it reduces the time and cost for regularly visiting the doctors at healthcare institutions. We have collected data from different ages’ patients by using three electrodes placements in their body and achieved 80% accuracy in our system. The data collected from our device has been directly sent to IoT cloud using ***Wi-Fi***. The IoT cloud has been used for visualizing the data to users and store it for future analysis. By using the system ECG signal can be monitored continuously. The regular use of device is very helpful for preliminary detection of heart diseases and to reduce severe damage and mortality rate due to cardiovascular diseases. Similar to this user-friendly ECG monitoring System, additional health monitoring systems such as temperature measurement, Blood Pressure, Diabetes, etc., can be developed using IoT that will greatly help decrease existing health care problems to a certain amount.

***Abstract*—In this paper, a customized clock and alarming system is developed, which can manage time and call the candidates sequentially during important viva-voice or presentation. The main purpose of this work is to free the intricacy of viva-voce or presentation time and to make it captivating to both the examiners and the examinees. To perform this action, we have utilized microcontroller, 32X8 LED dot matrix display, 6 digit multiplex seven segment display, radio frequency (RF) transmitter-receiver (Tx-Rx) pair, IR receiver, IR remote and buzzer. Seven segment display unit is used to show time, group number and also to produce an alarm to alert the presenter about the time during the presentation. User can set time and group number, start countdown and control other functions of seven segment display unit by an IR remote. Dot matrix display unit shows group number and other information to the waiting candidates which communicate with 7-segment display unit by RF Tx-Rx pair. By using this system only the examiner of the viva-voce or academic presentation can smoothly conduct the session without the help of an assistant.**

Keywords—matrix display, microcontroller, digital learning, wireless control, RF Tx-Rx; EUSART

I. INTRODUCTION

In the age of technology, people are utilizing technology to make their lives more comfortable and accessible. Every aspect of life is deeply dependent on technology [1]. Technology can be used to make the academic viva broad or presentation easy. The current method is not a convenient way, because the utilizer needs adscititious human resources and effort to manage the overall process, which lags the whole process.

Consequently, it would be more convenient if we can control the electronic contrivance instead of any other utilizer utilizing a remote unit [2]. An apparatus which can deal with time management and calling someone is different from each other. The time management system is a vital part in all over the world. Whenever in time management system it requires some exhibit where the time can be exhibited. Additionally, in the calling process, it can be an intercom bell or another contrivance is needed. Whenever we require both the device as a single contrivance, it's not available. But the method is the most frugal mode of consuming time over all other designates. Much related work has been reported for the same function by different groups with different approaches. Many home contrivances can be controlled with a designed system utilizing a microcontroller as the heart of the circuit with an android predicated mobile phone. Here the mode of controlling inventions is by sending command wirelessly through Bluetooth [3].

IR remote control has an extensive application in the field of electronics. IR predicated remote control for controlling multiple home appliances with the microcontroller is additionally reported for the same function [4], [5]. Another approach is by GSM-predicated for home automation. This is done by sending a short SMS code from a mobile handset. Here it has a broader coverage area. So to control any household appliances from a distance place within the network area coverage sending a short SMS code will either ON or OFF the contrivances at home [6], [7]. N. Sriskanthan, F. Tan, A. Karande [8] exhibited show for home mechanization utilizing Bluetooth utilizing PC. This use of Bluetooth innovation in home computerization and systems administration condition. They propose a method, which contains a remote, versatile host controller and a few customer modules (home apparatuses). The customer modules speak with the host controller through Bluetooth devices. Moreover, Bhawna Saini proposed Smart LED Display Boards which is aimed at the colleges and universities for displaying a day to day information continuously or at regular intervals during the working hours [9]. Additionally, Most of the previous works are individual devices. But in our project, it is the combination of all other project and also customized countdown clock is shown where user can set any time value, which is not explained by any previous projects.

This paper represents a system, where the user can control various electrical appliances by IR unit. A real-time watch has been added to select the time for each candidate. If it is necessary to add extra time, it may be possible. The clock display shows the decremented count per second and min. If the minute reaches within three minutes, a warning signal comes through the market. If minutes and seconds are empty, the final warning sound comes up. Alert is consistent with the sound time, and this word appears with Buzzer. Another unit can be kept outside the room, where the candidate has his seat. This unit is also controlled by the IR remote which is placed in the hands of the examiner. 8x4 dot matrix displays the number of specific candidates, each change in the display, and the lightning must raise a sound. The external unit can be controlled by the IR remote, but it can communicate with the

clock display within RF communication. Here, an 8-bit microcontroller ATmega328P is used, and the program "ARDUINO" software is written [12]. In this way, they maintain the fearless schedule, proper sequence, and alarming protocol to conduct a viva or presentation. This will make their exam enjoyable and productive along with the examiner. So the primary motivation of this project is to develop a comparatively low cost and more reliable system to conduct viva or any presentation.

II. System Overview

The system mainly consists of two parts: the remote controller and two display units. The microcontroller of the remote control unit detects a press in a push button. If the time is pressed for management, the clock display unit is ready. Besides, with the external unit operating, it sends a specific 8-bit code for the RF transmitter for each push button. The microcontroller of the display unit receives the code sent through the RF receiver through the refreshing controller[11]and accordingly controls the display accordingly shown in Fig 1.

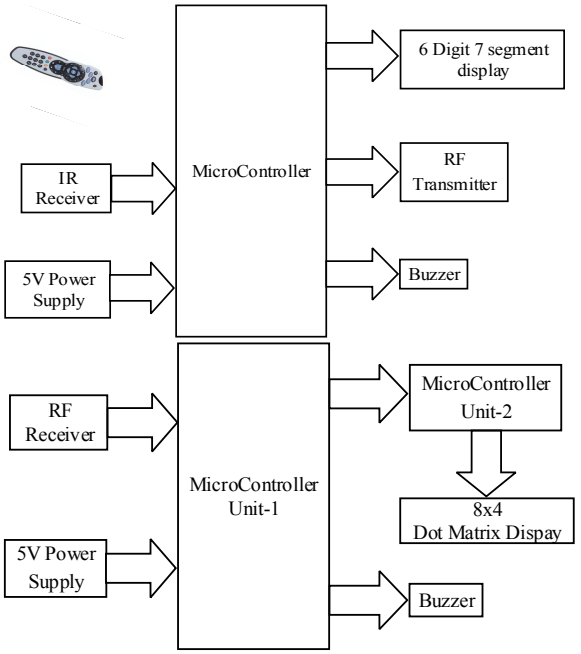

Fig. 1. Block diagram of the System.

III. System Desing

The methodology of developing the system is described in this section. The development process includes Interfacing 7 segment displays, receiving data from IR remote, Data transmission & receiving through the RF module, scrolling process in a dot matrix display and finally the complete circuit diagram of the system[9].

A. Interfacing 7 segment displays

At the very beginning, we have to convert BCD numbers into the 7-segment format and generate the respective decimal value for every BCD number. Then we create masking to separate the bits. After separate the bits, it sends to the appropriate output pin as the desired segments. The process of masking is the AND operation between two decimal codes, where we can separate each Binary value for the respective layers. For BCD value is 0000, the Decimal value is126 and for BCD 0001, Decimal value 48 are shown in "Table. 1".

TABLE I. CONVERTING BCD TO 7 SEGMENT FORMATS

Decimal Digit	BCD	g	f	e	d	c	b	a	Binary to Decimal
0	0000	0	1	1	1	1	1	1	126
1	0001	0	0	0	0	1	1	0	48

At first, we check the test value to light on the b segment only. So, we create AND operation between the Decimal value of 48 & 32. After AND operation, appropriate amount sends to the appropriate output pin as the desire segments are shown in "Table. 2". Then we need to select the display to show the desired value. In clock display unit we have 6 seven segment displays. When we need to show the value, these display selection line needs to high, and the rest of them goes to low. To show 1 in the first 7 segment display out of six 7 segments, data is a mask in the segment pin as 0110000 and selection pin S6 needs to high, others selection line goes to low at that time.

TABLE II. MASKING TO SEPARATE BITS

Segment	a	b	c	d	e	f	g
48	0	1	1	0	0	0	0
32	0	1	0	0	0	0	0
AND operation	0	1	0	0	0	0	0

B. Receiving data from IR remote

Here TV remote, an IR LED is utilized to transmit information to the contrivance. IR receiver in at clock exhibit picks out signals from remote through modulation. A mundane modulation scheme for IR communication is something called 38 kHz modulation. When we hit a key on our remote, the transmitting IR LED will blink very expeditiously for a fraction of a second, transmitting encoded data to the contrivances. The data word is reiterated as long as a key is pressed. In a data word which consists with 2 start bit, 1 toggle bit, 5 address bit, 6 data bits. In our remote panel utilize a space-coding method in which the length of the spaces between pulses of light represents a one or a zero which displays in Fig 2.

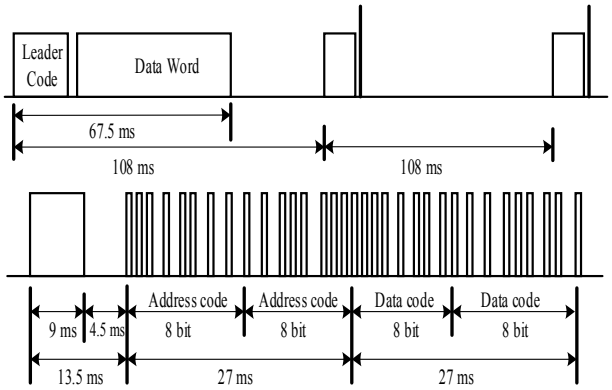

Fig. 2. Data format of IR remote.

C. *Data transmission & receiving through RF module*

Data transmission through the RF module, depends on the three units in Fig 3, which are Start bit, Clock bit and a Data bit. In Start bit occurs with every interruption. When an interrupt occurred, then the clock bit generated. Defines no of bit transferred for each code and synchronize the transmission between receiver and transmitter. In the time of the clock, a bit data bit can be sent to the receiver. The Status of each data bit d3d2d1d0. Same as Data transmission, Data receiving through RF module depends on the three units. When an interrupt occurs receiver unit start collecting data for a pulse. In clock bit, for the rising edge of the clock data is read in the data pin after that mask operation is used for separate the data value and sends the value to the specific data pins.

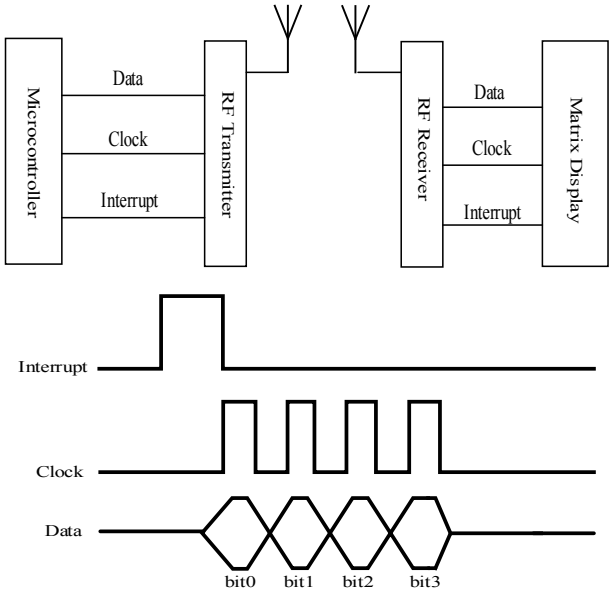

Fig. 3. Data transmission & receiving through RF.

D. *Scrolling process in dot matrix display*

We want to display the digit 1. We will first select the row as R1 data is required to scan the first row as 00011000 and deselect other rows by blocking their ground paths. Now, the first row is active. Next, select the row R2 and so on. Therefore, by scanning across the row quickly (> 100 times per second) and turning on the respective LEDs in each row of that column. In that way 64 bit required to show a character. For the scrolling process, we have used Max7219 display driver for left shifting. The persistence of vision comes in to play, and we perceive the display image as still. In Max7219, depends on the three units, Data IN, Clock and load. Data is required for the scanning process. The clock is used to receive the input data, and load pin requires loading the data to the device.

E. *Complete circuit diagram of the system*

The complete circuit diagram of the system is shown in Fig 4. Arduino Uno board is used here which has Atmega328 microcontroller. The OUT pin of IR receiver is connected with digital I/O pin 0 of Arduino Uno. The digital output pins 3-14 control the Clock display unit, digital output pins 10-13 controls the RF transmitter unit and finally digital output pin 2 controls the Buzzer unit. In receiving circuit, the OUT pin of RF receiver is connected with digital I/O pins 2-4 of Arduino Uno. The digital output pins 10-13 control cascade microcontroller unit and pin 8 controls the Buzzer unit. In cascade microcontroller used for controlling the Matrix display unit in digital I/O pins of 10-13. Logic HIGH in such a pin executes the specific operation. This is the principle to create a closed path in the load circuits: a single press in the reset button, both the display unit ready for the initial stages. The user can adjust the timer and calling the specific candidates by up and down button. When click the start button both the display units run perfectly.

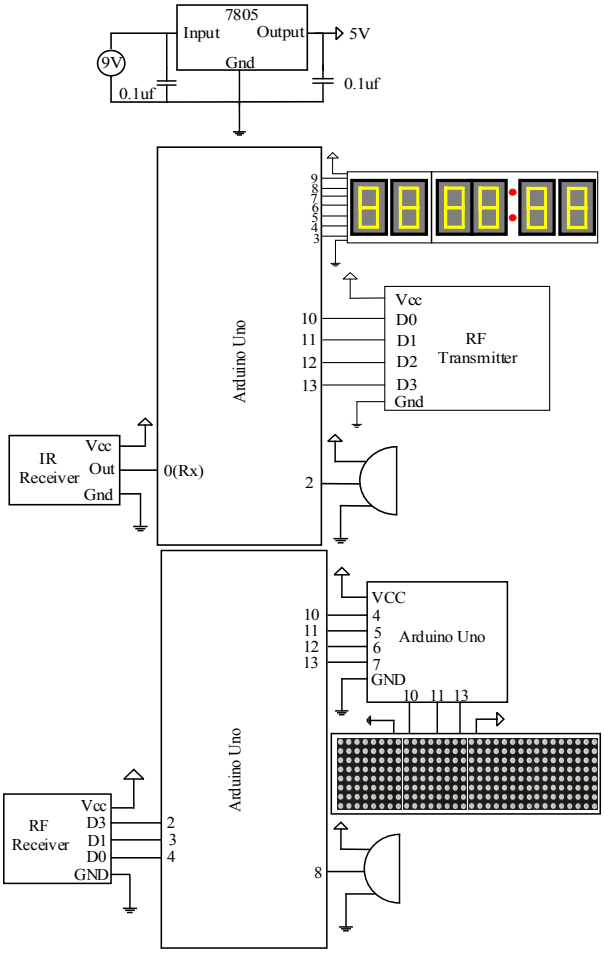

Fig. 4. Complete circuit diagram of the system.

F. *Flow Chart*

The flow chart of the whole system is shown in Fig. 5. it is divided into two parts. The first one is the sender and the second part is the receiver. In the transmitter part, after starting of the program data from IR receiver will be taken. If the data of the IR transmitter is 0x38863BE0, it active the clock system as 1min. Along with 0x38863BD0 as 2min and 0x38863BF0 as 3min. After that, it waits for starting the timer. If the data is 948321234, the countdown timer will start. When minutes & seconds close to zero or minute=3, the buzzer is active. If the data is 948321242, it will reset the clock display. If the data is 948321266 or 948321274, it transmitted increment or decrement logic state to the receiver part via RF communication. In receiver part Fig 6 and 7, after receiving the data from a transmitter, the system will be activated. If received data is greater than zero, the text of the group number is incremented than it will decrement the group number with the decremented logic state. In every new group

number, a buzzer will remain active and give the sound of the alarm.

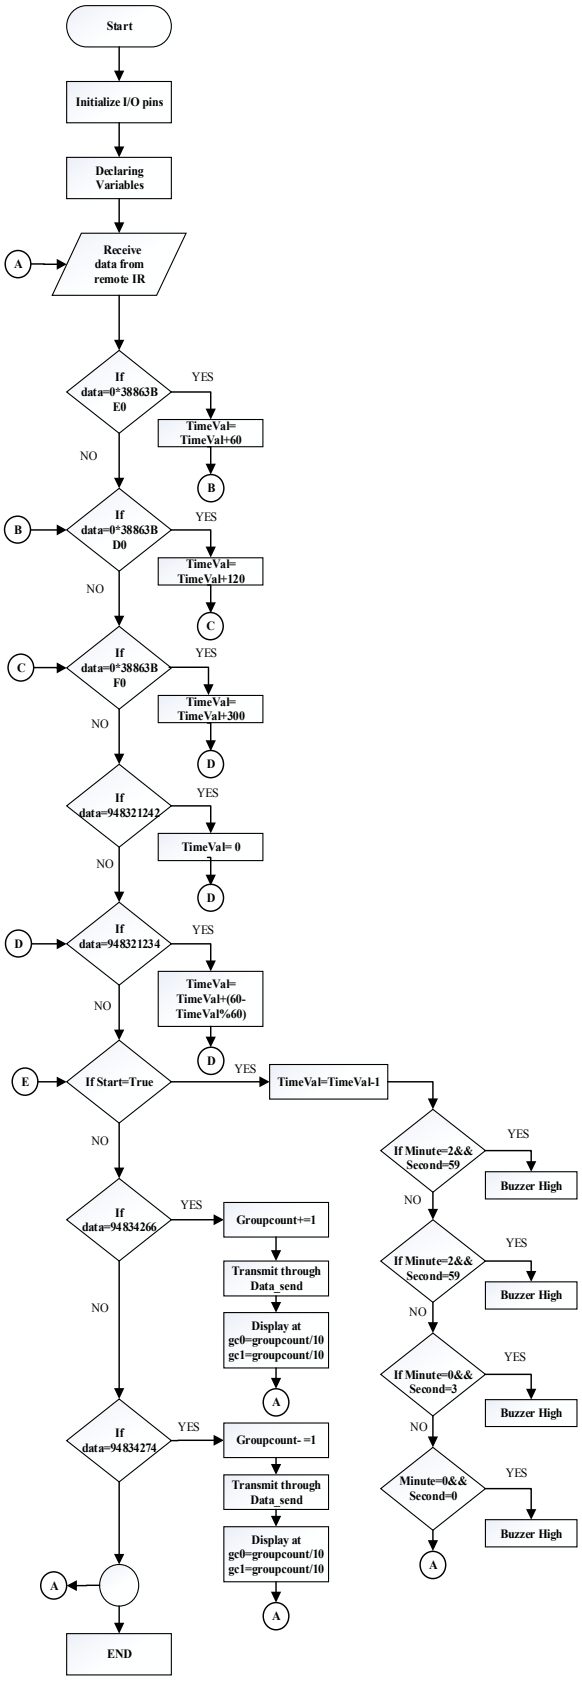

Fig. 5. Flow Chart of the system Transmitter.

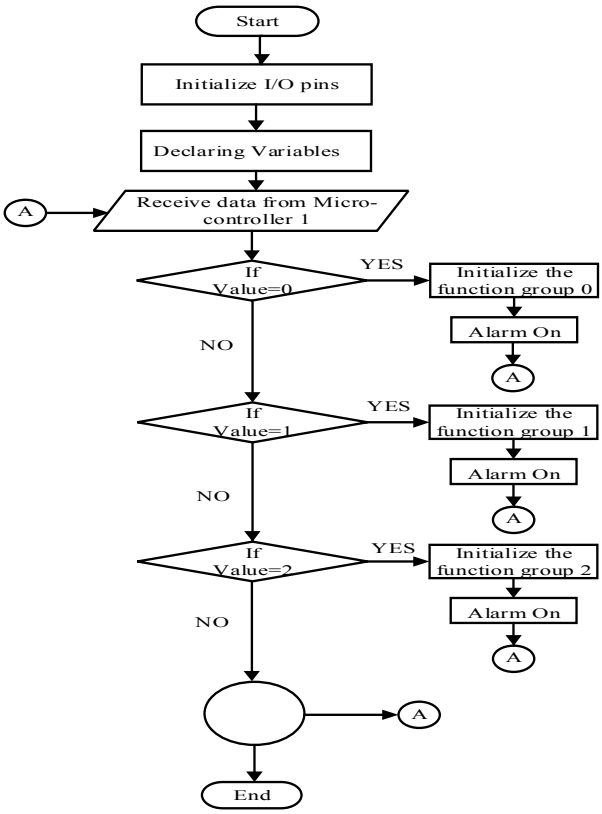

Fig. 6. Flow Chart of the system Receiver-1.

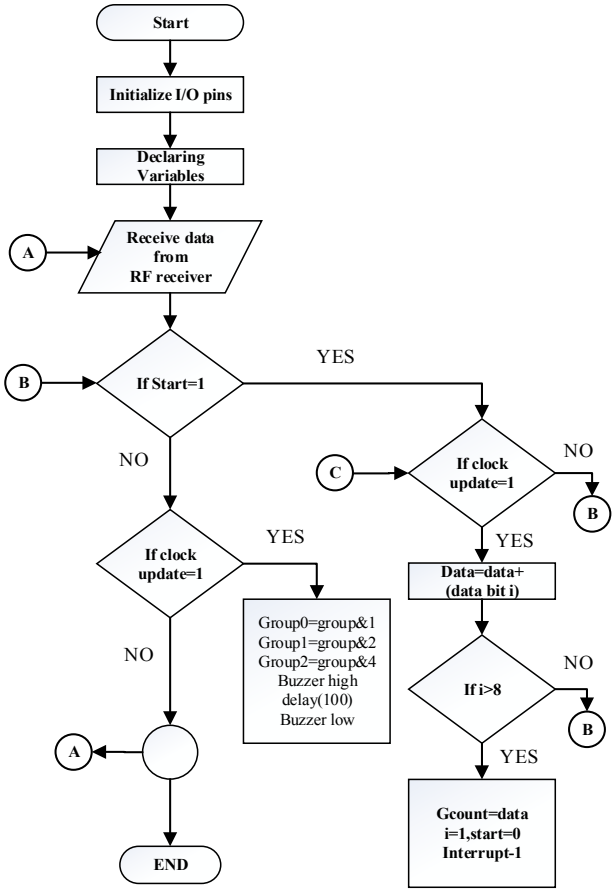

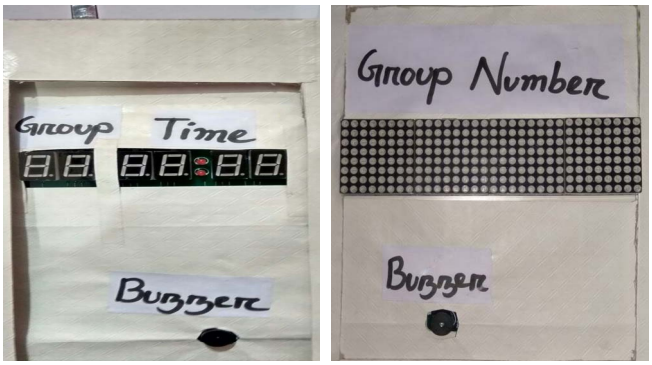

Fig. 7. Flow Chart of the system Receiver-2.

IV. Result and Implementation

The system is implemented as a prototype to check its eminence. Fig. 8, Fig. 9and Fig. 10, shows some images of the prototype. As the system is a wireless controlled system so it works for the IR & RF communication within a limited distance. The prototype of the system can work for the IR remote within 7m distance and the RF transmitter inside the room & receiver outside the room within 11-meter distance. The device can take power from a 9V battery providing current up to 1 amp or, it can be connected directly 220V supply through a 9V adaptor. In the prototype of the system, two display unit named as clock display and another one is group display unit. The buzzer is connected in each display unit. Initially, the system needs to reset. In this state, the reset command needs of the clock display and group display unit showing welcome text.

Fig. 10. Hardware implementation of the system.

V. Conclusion

The system has a unique advantage over other the conventional process. Controlling electronic appliances by RF or IR remote is exciting and enjoyable for all. Anyone can operate this device, and the total process executes in sequentially. Another advantage of this system is that user can manually adjust time and every time ends an alert sound reminds for the timing and also this is low power consumption electronic device. So there is no risk of short circuit or fire. If we replace any human through by our device, we can save more time in interview and presentation. Moreover, there have some limitation such as here start button is required to double press for starting the clock display and the maximum limit to operate the transmitter and receiver device is approximately 11 meter. Furthermore, Though RF-based communication has many desirable capabilities, it has some drawbacks too such as Antenna installation should be careful. Future work can be done adopting an extension of this other language besides English.

***Abstract*—Water is a vital element of nature. People would not think of a single day without it. Water becomes more important when there is scarcity of it. Mostly developing countries are facing this issue. Moreover, the people of these countries are not aware of wasting waters. Safety of water is one of the important solutions to this problem. A smart water management system is presented in this paper to remove the water wastage and energy loss at house. In this system, there are two motors. One motor is controlled by Arduino Uno to fill the water tank and another motor is managed by C# (c sharp) desktop application to distribute water to the users through an optimal way. To recognize water level, the research has not implemented any sensor. Instead, wires are used to sense the level. Water tank automatically starts to fill up with ground water by the first motor when water reaches down to a certain level, 2) the motor will be switched off and alarm goes on to notify the owner when the water gets up to a fixed upper level and 3) the owner gets notification that tank is full on the desktop and later he can switch on the 2nd motor to provide water to the users and to control usage of water through desktop application sitting in his home whenever users need. Moreover, application will show that on a single day how many times 2nd motor is set on. Thus this approach gives an automated and hassle-free model for the people in order to control the home water system and provides optimal water consumption.**

***Keywords*—Smart water system, Arduino, Automated system, Desktop application, Without sensor**

I. Introduction

Fresh water is generally used for drinking, household works, industrial uses, irrigation, and livestock and aquaculture etc. all over the world. These uses are increasing rapidly as the temperature changes and the population is growing. On the other hand, climate change puts a huge impact on water shortage. In this situation, water wastage can bring a biggest fall in the environment. It can be wasted on water supply system at home, plant-irrigation, industrial works etc. Many researches have been done to eliminate this problem. Authors of [1] proposed a system for saving water in plant irrigation. A system, designed for physical disable patients, had a good impact on saving water [2]. Another automated plant-irrigation system was proposed in [3].

This paper focuses only on the wastage of water at human houses. Today one of the problems is people have no idea when their water tanks gets filled up. Sometimes there are situations where the pump keeps on pumping water to the tank and the water starts spilling out from the tank. This makes wastage of energy as well as wastage of water. To reduce the wastage of water at house, the target of this paper is to build a smart and automated system where the owner of the house can monitor the system in his desktop application. The water tank will be automatically filled up with ground water. When the tank becomes full, the motor will be shut down and the owners get notified by the alarm as well as notification on his application. Later, he can provide the water when the users need by switching buttons on the application. Supplying water to the tank is occurred according to the water surface in the tank. The desktop application interface is easily operated. Detection of water is prime matter in this part. It can be carried out by sensors. But usage of sensor is expensive. To accomplish the identification of water level, wires are used. When wires get touches with these water, they send HIGH signal to the Arduino. This approach is less costly, user friendly, automated and fully controlled. It can be added to smart home automation system with a view to saving water and energy.

II. Related Works

Most researches on smart water system are proposed for water-irrigation and smart home technology. An IoT based automated system was discussed for water monitoring in [4]. By this model, user can monitor the water usage and wastage through mobile. M. Asadullah et al. presented a home automation model using sensors, Arduino, smartphone and bluetooth [5]. To track household water supply and billing, in [6] an automated model was showed. Their model had features of switching motor based on the water level and billing system. Arduino mega 2560 and sensors were used in this system. T. Mantoro et al. [7] proposed a saving water system for smart home bathtub according to the water level. They also used sensor for water level detection. In [8], authors

had a method to watch and estimate the consumption of the water through a web server. They used Hall Effect sensor for measuring water flow rate. Previous researches in this field rarely discussed about the water wastage at household tank (which supplies water to the users). It can make a huge loss of water and energy. Again most of the papers implemented sensors for detection of water and other related works which is quite costly. Therefore, there must be a system which is less expensive, automated and monitored by computer for ideal water consumption at house. Proposed approach is having these working features.

III. Proposed Model Description

The system has been implemented using Arduino Uno, DC motor, 100k resistors, wires, buzzer and computer. In this process, there are two motors, one motor is used for pulling water out of the ground and store water in the tank which is situated at the top of the house. Another motor is for providing water to the users. So this system consists of two parts.

- The tank is automatically filled by Arduino Uno based on the water level using the 1st motor
- Desktop application controls the water distribution through the 2nd motor

The system flow diagram is presented in figure 1.

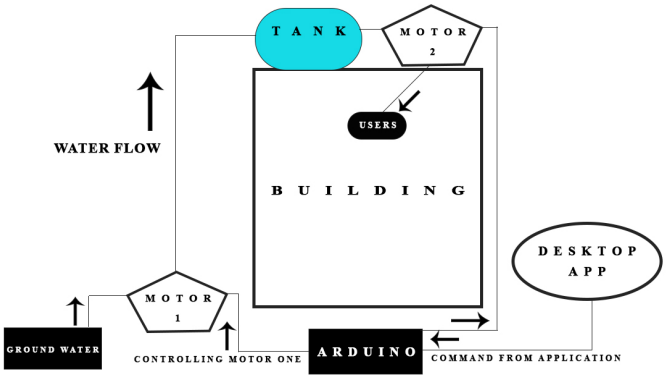

Fig. 1. Proposed System

A. A. Water level detection and motor 1 control

In this system, the identification of water level is done by setting parallel wires in the tank. Generally, ground water is impure and this kind of water is perfect for conducting electricity because it has some ions such as calcium and magnesium and these ions are good conductors. The idea is two wires are put in tank very closely. When water touches these two wires there generates some electricity and later we check the status of the wire in the Arduino. If status is HIGH, we get to know that water is now at that level. In this experiment, motor 1 works based on two water levels (upper and down). So, there must be four wires in total for level detection. Two wires in the top level and another two wires in the bottom level (Figure 2).

When the tank is set up for use, it is empty. That's why both down level and top level wires are LOW at that moment. Arduino Uno senses the signals from the wires and turns on the 1st motor to pull up the water from the ground to the tank (Figure 3).

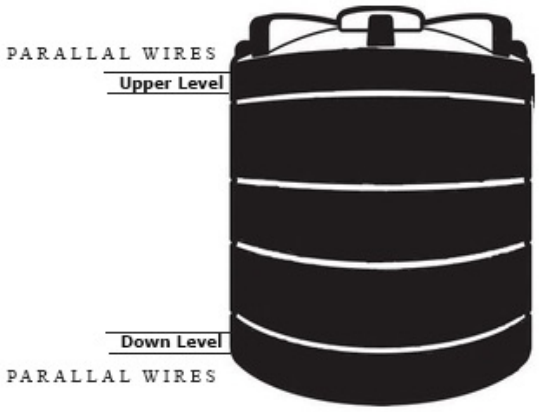

Fig. 2. Wires working as Sensor

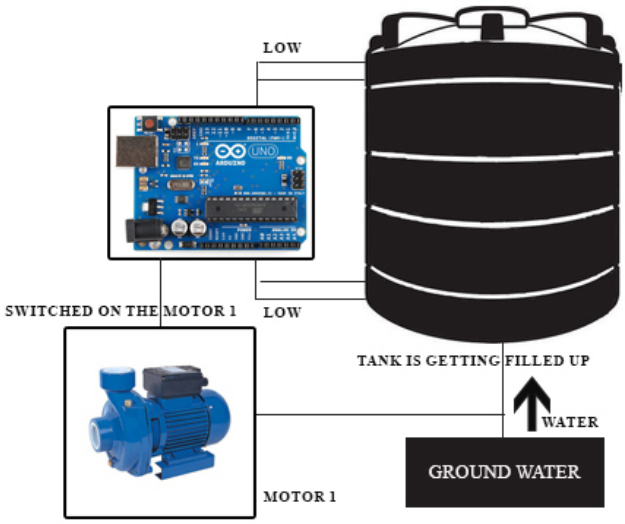

Fig. 3. First Phase- Tank is getting filled up with water

By this way, tank is going to be filled up with water by the motor 1 until the water touches the upper level. When the water surface is above the down line and below the upper line, down wires and upper wires will provide HIGH and LOW signals respectively (Figure 4).

After a fixed amount of time, tank will be full with water. During this time both upper and lower wires provide HIGH signal. While Arduino gets these signal, it will turn off the motor 1 (Figure 5). A buzzer which is connected to the Arduino for providing alarm to the house owner to indicate that there is sufficient water in the tank, goes on for few seconds.

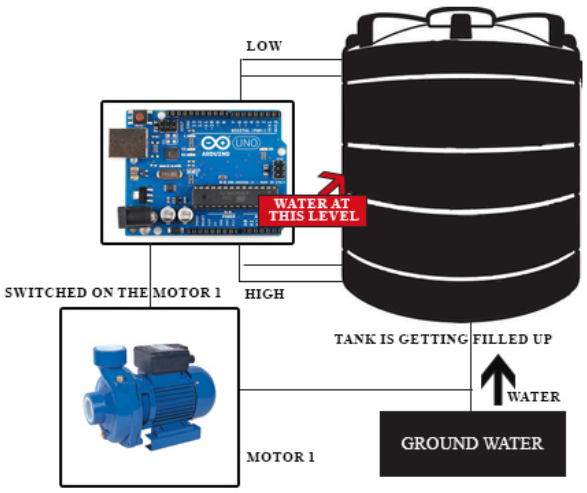

Fig. 4. Water surface between lower and upper level

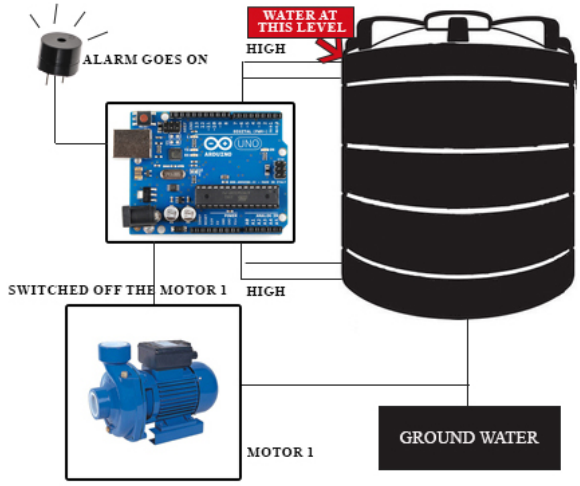

Fig. 5. Motor 1 is switched off and Alarm goes on

B. Desktop Application

To provide a hassle-free system for the house owner, this experiment has a desktop application. From the figure 5, we see the owner will be notified when the tank is full by the alarm. Later, he has ability to control the water distribution for the users. When he switches on the motor 2 through this application, the 2nd motor provides water to the building or the house (Figure 6). Desktop Application Interface is shown in figure 7. There are two buttons. These are for controlling 2nd motor. After consumption of water, when the tank becomes empty, upper and lower level wires will signal LOW. At this time, if there is no water and 2nd motor is still on, any damage can be happened. Also, suppose owner of the house unintentionally starts 2nd motor in this type of situation but Arduino let not him/her to do. To avoid any accidents, Arduino turns off the motor 2 and turns on the motor 1 whenever both pair of wires signals LOW. There rises a question, if Arduino shuts off the 2nd motor, then there should not be any OFF button in application. Suppose a situation, while there is enough water in the house and the 2nd motor is turned on, user continuously gets water but they need not it at that time. This can make water wastage. So to get rid of this problem, owner can turn off the 2nd motor by using OFF button during this situation. Also there is a counter of how many times 2nd motor is turned on a particular day. By this counter, owner can track the water usage. Full architecture of the proposed system is shown in figure 8.

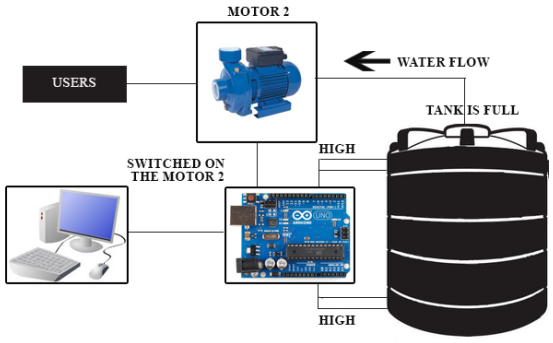

Fig. 6. Water distribution to the users by the Application

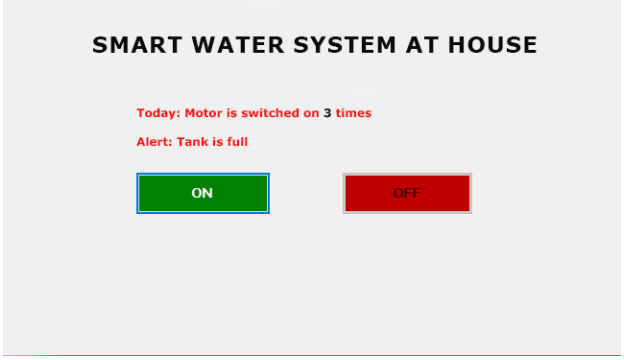

Fig. 7. Application Interface

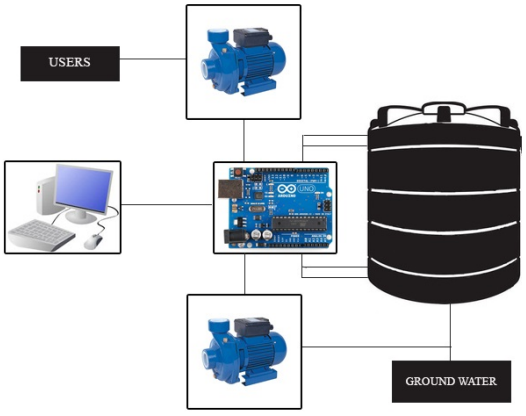

Fig. 8. Full Architecture of the Proposed System

IV. Hardware Model And Pseudocode

Figure 9 shows the implementation of hardware model.

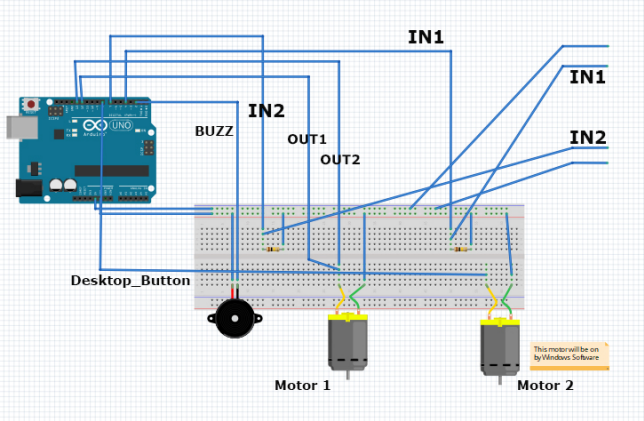

Fig. 9. Hardware Implementation

Algorithm 1 Algorithm

```
1:  procedure SmartWaterSystem
2:  loop:
3:      if (in1 == LOW and in2 == HIGH ) or (in1 == LOW and in2 == LOW ) then
4:          out1 ← HIGH
5:          out2 ← HIGH
6:          buzz ← LOW
7:      else if (in1 == LOW and in2 == LOW ) then
8:          out1 ← HIGH
9:          out2 ← HIGH
10:         buzz ← HIGH
11:         desktopButton ← LOW
12:     else if (in1 == HIGH and in2 == HIGH ) then
13:         out1 ← LOW
14:         out2 ← LOW
15:         buzz ← LOW
16:     if (seriaData == "O" ) then
17:         desktopButton ← HIGH
18:     else
19:         desktopButton ← LOW
20:     goto loop
```

In algorithm 1, the model seems to have a problem in a situation when the water surface reaches at the top level and IN1, IN2 gets high then motor1 is shut down. Later, while motor 2 is on, the water level gets below of the upper level. So based on the condition (on line 3) the motor 1 becomes on again. The motor 1 is going to be continuously on and off. This can destroy the system and any harmful damage can be occurred.

To avoid this issue, we can use FLAG variable. Algorithm 2 is the updated version of algorithm 1. In algorithm 2, at the beginning FLAG is declared to be false. While IN' and IN2 are LOW, then the tank is becoming filled up (on line 11) and

Algorithm 2 Revised Algorithm

```
1:  procedure SmartWaterSystem
2:      flag ← false
3:  loop:
4:      if (flag == true) then
5:          if (in1 == LOW and in2 == HIGH ) or (in1 == LOW and in2 == LOW ) then
6:              out1 ← HIGH
7:              out2 ← HIGH
8:              buzz ← LOW
9:          else
10:             flag ← false
11:     else if (in1 == LOW and in2 == LOW ) then
12:         out1 ← HIGH
13:         out2 ← HIGH
14:         buzz ← HIGH
15:         desktopButton ← LOW
16:         flag ← true
17:     else if (in1 == HIGH and in2 == HIGH ) then
18:         out1 ← LOW
19:         out2 ← LOW
20:         buzz ← LOW
21:     if (seriaData == "O" ) then
22:         desktopButton ← HIGH
23:     else
24:         desktopButton ← LOW
25:     goto loop
```

FLAG becomes true. As FLAG is true, tank is preceded to be filled up. Motor 1 gets stopped after IN1 and IN2 both are HIGH (on line 17). As flag is true and IN1 and IN2 are HIGH, the condition on line 9 becomes true, the FLAG is set to be false. Next time, the owner turns on the motor 1 but as FLAG is false the motor 1 will not be switched on until the water reaches down to the lower level. For controlling 2nd motor Arduino gets two input from serial port by desktop application. When "ON" button is clicked on the application Arduino gets "O" from serial port and when "OFF" is pressed, it gets "F" as input. Based on this input from serial port, Arduino change the status of the 2nd motor as follows-

- When Arduino gets "O", it turns on 2nd motor by setting desktopButon port as HIGH and
- Shuts down the motor by setting desktopButon port as LOW When it gets "F"

V. Conclusion

Countries such as Bangladesh, India etc. are having lack of water for their people. And general people of these countries are not concern about water wastage at household. They need a smart, automated and easy approach for operating household water system to reduce water loss as well as energy loss. Proposed system brings up this kind of solution and does not use any sensors which brings down cost. This system is effective for people of developing countries.

***Abstract*— Cities where water supply system follows trivial analog system like Dhaka city, a twenty-four hours monitoring is required to start the water pump immediately when water is available in the main water supply line. A significant amount of water can be wasted only for the reason of overflowing the water tank. Thus, the aim of this paper is to propose an automated water pumping system to minimize the wastage of time, money, labor and water loss. A high-fidelity prototype system was designed and developed using the Arduino Uno, water pump, potentiometer and relay switch; and able to control its operation automatically with respect to the availability and amount of water in the main water supply line and the reserve water. An evaluation study was also conducted to assess the availability and reliability of the system. The evaluation results showed that the proposed system is reliable, available and cost-effective.**

Keywords—Artificial intelligence, water pump, water supply management, intelligent system.

I. Introduction

Dhaka city, the capital of Bangladesh, is one of the most densely populated areas within the country with around 13 million people. So, the people in Dhaka city require a huge quantity of water for different purposes everyday. Moreover, there is a large number of industries along with other organizations which require water supply for their operation. According to Dhaka Water Supply and Sewerage Authority (DWASA), considering water demand as 20 l/p/d (litre per person per day), total water demand in Dhaka city varies from 2300 to 2350 million litre per day (MLD), while the total production capacity of DWASA is 2450 MLD including both ground and surface water [1]. The DWASA is thus able to fulfill the current water demand. However, since the water level is decreasing day by day. So, it is obvious that water supply will not be sufficient against the demand and people will not get water on the water line for the whole day.

Again, the issue of ensuring enough water supply in Dhaka requires adoption of the most effective, efficient, relevant and appropriate systems which must be cost effective as well. As water is not available all the time in the main line, people always need to be concerned about the reserved water level so that the pump can be switched on as soon as the water is available. Moreover, people have to be conscious when the water tank is full and the pump needs to be switched off. Otherwise, a huge quantity of water can be wasted by overflowing the water tank. To perform all these, it is not easy for a person or an employee (which may cost) to check the availability of the water throughout the whole day.

Therefore, the aim of this paper is to propose and develop an intelligent cost-effective automated water pumping system. To attain this research objective, a prototype of the automated water pumping system was developed and an evaluation study was conducted to measure its performance.

The rest of the article is organized as follows: Section II presents related works, Section III discusses the implementation of the system, the evaluation of the system is discussed in Section IV and finally Section V contains conclusion and future expansion.

II. Literature Review

This section will briefly introduce related works focusing to the design and development of the water pumping and management systems.

Astrom [2] invented a water pumping apparatus which was basically used to develop a water pumping system and was suitable for home and farm use. On the other hand, Eusuff and Lansey [3] proposed a system named SFLANET which actually linked Shuffled Frog Leaping Algorithm and the water distribution system to develop a better water supply system that offered a better water supply system for the citizens. But the improved water distribution network had a very high computational complexity.

Oi [4] introduced Photovoltaic water pumping system using Photovoltaic modules and DC motor by simulating the model in MATLAB. Abdolzadeh [5] worked to improve the effectiveness of the system. He also evaluated the functionality of his system. Hsiao [6] coupled among a photovoltaic power source, a solar panel and a pumping system. Later, Kohle [7] analyzed the performance of Directly Coupled Photovoltaic Water-Pumping System.

Meierhoefer [8] proposed a model which used a device that boosted hydraulic pressure as well as the in-line water pressure. The model could take necessary steps by sensing the current condition of water demand and water discharge line. An additional pump was used here to support the pump pressure. Again, Ormsbee [9] examined different models including hydraulic network model, demand forecast model and optimal control models for both single and multi-source water-supply pumping system. He listed the important factors for optimization such as- operating cost, physical system

limitations, governing physical law, externally defined requirements, the maintenance cost of the pumping system etc.

A number of researches has been carried out to develop and design an optimized model of water supply system. Crawley [10] developed a multi-reservoir system with an experimental model which was basically a monthly optimized planning model with minimal system reliability. He also developed an experimental model to ensure that the model reduced 5% to 10% of pumping cost. Later, the system was adopted by the local authority named Engineering and Water Supply Department (EWSD). Similarly, some other researchers [11]–[13] also adopted the multi-reservoir concept in developing the water pumping system. Yu [14] focused to the pumping schedules as a solution to water distribution system. He also provided test example to validate his research work.

Jowitt [15] introduced a optimization procedure to determine the structure of optimal pump scheduling process or electricity tariff with available pumps. Basically, it worked by considering the unit and maximum electricity charges, efficiency of relative existing pumps, demand of the consumers and operational constraints of the network. Nitivattananon [16] developed another model for optimization of water supply system operation to generate the pump schedule in real time operation including monthly billing. It considered the major difficulties of a complicated tariff, discrete discharging of pumps, charging of demands etc. A simulation for a test showed that 20% of the actual cost could have been saved applying this model. Coulbeck [17] proposed a procedure to optimize the unit costs and demand charges, and to derive the maximum flow requirements for the tariff period.

McCormick [18] acquainted a stochastic dynamic program-based system to optimize the water-supply system. He showed that the scheduling for the pump switching on/off can be sometimes complicated when the maximum demand charges which can't be ignored, are involved in electricity tariff. In his paper, he considered some medium term maximum demand policies and some constraints in daily pump scheduling. He also proved the method better than using heuristic techniques because this model considered the demand for water is not settled. Shu [19] worked to optimize the power consumption in water pumping system by using hybrid genetic algorithm. His optimal controlled model was applicable for wide range of water supply system which could calculate the lowest cost after preserving the performance for each station. He was able to reduce power consumption by 6.04% than before which also reduced the pumping cost. Beckwith [20] contributed in Artificial Intelligence field by choosing a Genetic Algorithm approach of natural selection with a fitness function, to optimize the cost for the operation of a multi-storage, multi-source water supply system. He developed a genetic algorithm to ensure that the pumps in the system are adequately providing the required volume/amount of water in the water distribution system with minimizing the cost for the usage of electric energy by the pump/motors. Moreover, the algorithm considered some factors like- the efficiency curves and the flow limits of pumps in the system.

Reza [21] showed a microprocessor-based process to control the pumping schedule which senses empty or full tank by controlling on/ off signal. The system included PIC with sensors to sense the water level with LED lights as indicator. Stene [22] constructed a model for hot water supply system and evaluated the system to measure the performance for some specific operating conditions, while Zongxuez [23] carried out a simulation based study to measure the performance of the water supply system in Fukoka city.

The literature review showed that though a few works have been carried out related to the water pumping system, but no work explicitly focused in the context of Bangladesh. In Bangladesh, especially in Dhaka city cost is not only the crucial factor but also the availability of water (i.e., preserving the water for future use) is a key concern. Thus, this research aimed to develop a smart water pumping system to be used in context of Dhaka.

III. Implementation of the System

A. Equipment

To develop the prototype of the proposed automated water supply system following hardware were used:

1) Arduino Uno: Arduino is an electronic platform to control according to the input and give output by hardware and software programmed for it. This device is cost-effective, easily accessible and used in developing a number of intelligent and assertive systems [24]–[27].
2) Water Pump: Water pump is an electric machine that turns electrical energy to mechanical energy.
3) Potentiometer: Potentiometer is a resistor of three terminals which can adjust the voltage drop. Potentiometer is usually used for controlling any electrical device.

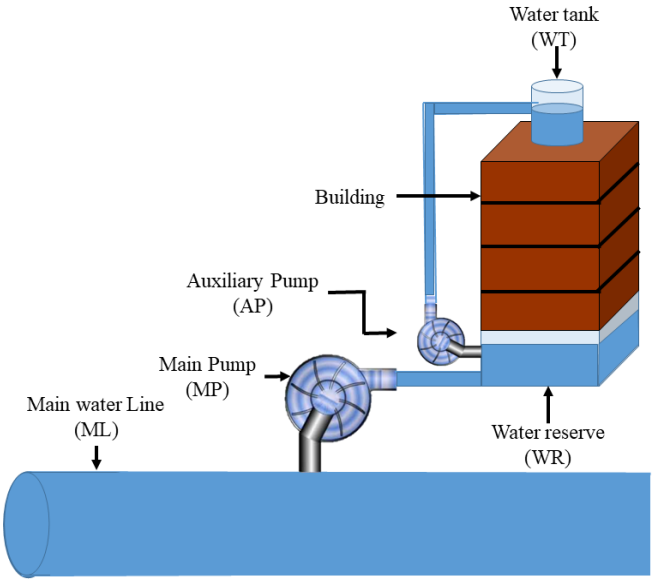

Fig. 1: Overview of water pumping system

4) Relay switch: Relay is a magnetic switch which is operated electrically and used for energising or accelerating the electrical signal to required state.
5) Two containers as upper water tank and reserve were used as well.

B. Prototype

A high-fidelity prototype of the proposed system was developed as showed in Figure 1. In this proposed model, Main Pump (MP) was placed with the main line (ML) to get water from the main line to the building. Water Reserve (WR) was placed under the building and the upper Water Tank (WT) was at the top of the building. When water was available inside ML, the system sensed it and automatically started the MP (if the WR was empty or under certain amount according to the expected amount). If WR was full and WT was empty or under certain amount, the system automatically switched on the Auxiliary Pump (AP). The starting of MP and AP depended on certain condition or amount of water in percentage. Thus, the system automatically worked to provide water in maximal beneficial and minimal costly way.

C. Working Principle

The working principle of this proposed water control model is quite simple and can be described as follows-

- Start the main pump when water is available in the ML and continue pumping until the WR is full.
- If 80% water is present in WR and MP is still pumping water and the WT is not full, the AP will start filling WT until it is full or MP is off.
- If water in WT is less or equal than 10% and if the water in WR is equal or more than 40%, AP will start automatically and fill WT up to 30%.
- If the WR is full, the MP will stop automatically.

The system can be depicted more clearly by the flowchart shown in Fig. 2. Decisions were taken at different phases of the system to start or stop pumping water automatically.

The percentage of the amount of water was measured by the concept of electrical circuit. In different levels of the upper or reserve tank, the wires of the different percentage labeled were clipped or attached with a conductor. If water reached any level then it makes a closed circuit so that

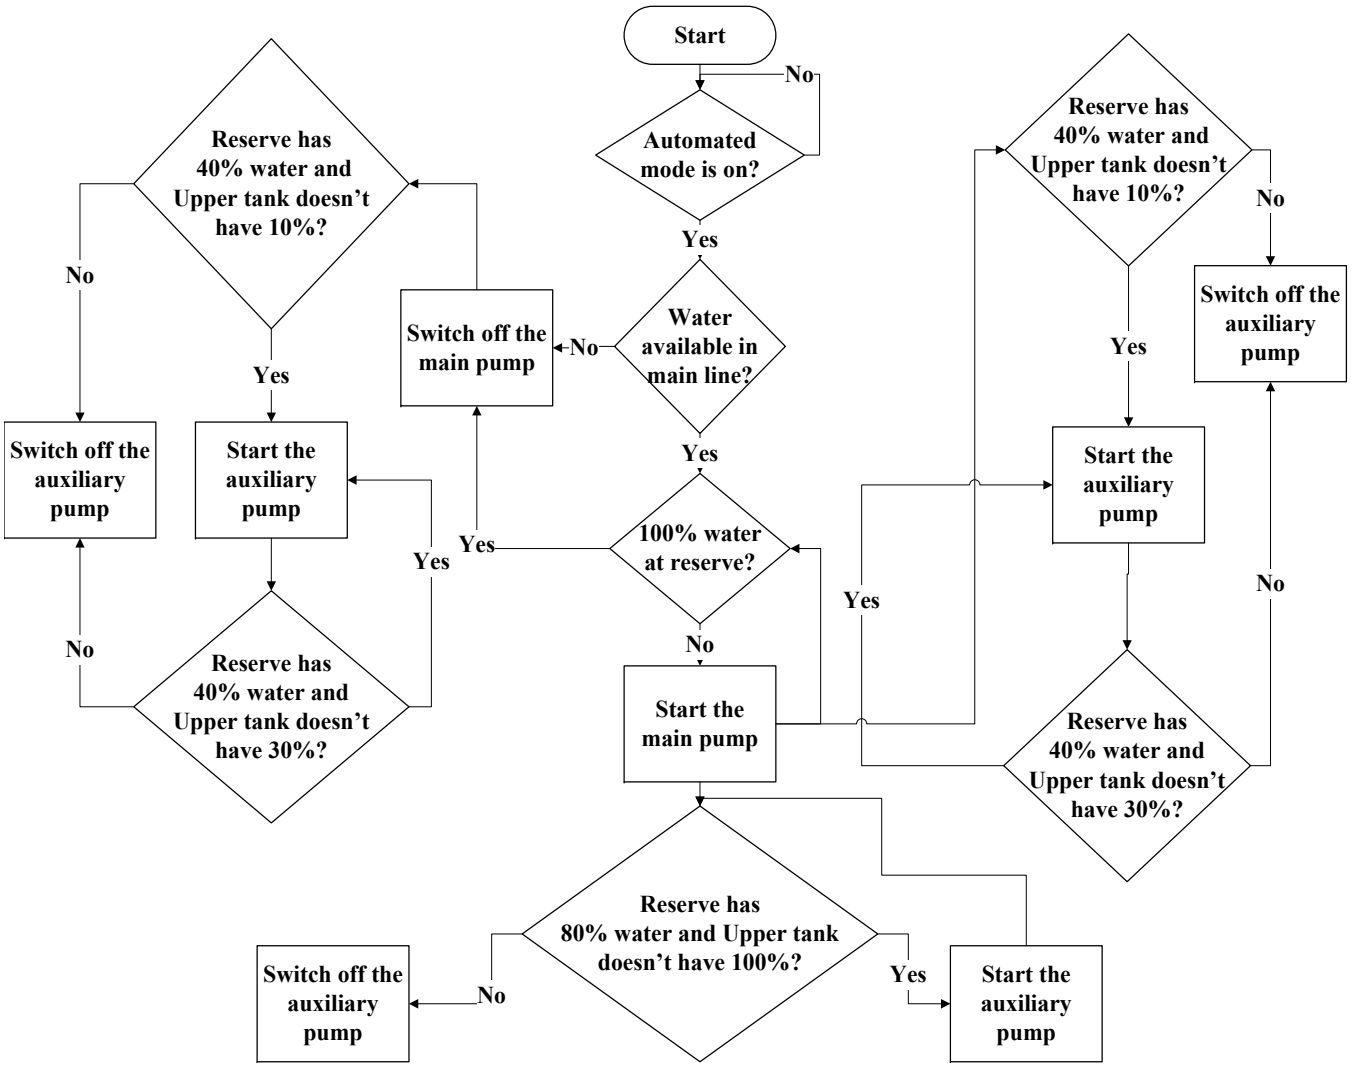

Fig. 2: Flowchart of automated water pumping system

Table I
THE OUTCOMES OF THE EVALUATION STUDY

Condition	Action	No. of Trials	No. of Success	Success Rate	Avg. Delay (second)
Water is available in ML	START MP	20	19	95%	0.9155
80% water in WR and ML is ON and WT is NOT FULL	START AP until the WT is FULL or MP is OFF	20	18	90%	1.141
Water in WT <= 10% and water in WR >= 40%	START AP to fill up WT up to 30%	20	16	80%	1.2605
WR is FULL	STOP MP	20	19	95%	0.8225

electricity can flow. The potentiometer used in the system, basically converted the water level to voltage drop. If there was no water in the WT, potentiometer showed 100% voltage drop for open circuit. If water rose up to certain level, the potentiometer showed certain voltage drop for closed circuit. From the reading of the potentiometer, the level or amount of water could be measured. A program was developed and loaded in Ardunio to analyse the all input data in order to provide decision of the switching on and off the motor.The main circuit implementation to develop the prototype is presented in Figure 3.

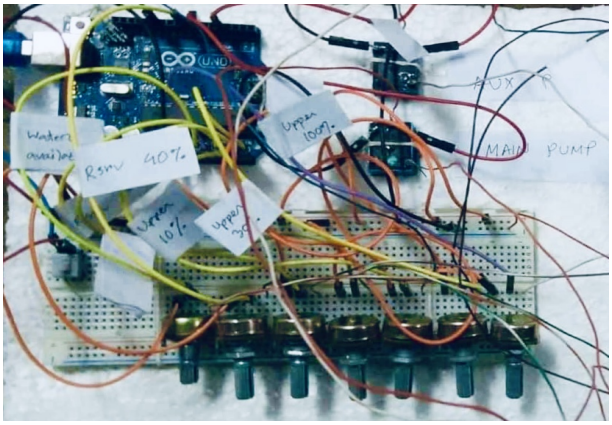

Fig. 3: Hardware components with circuits to develop the prototype

IV. EVALUATION OF THE SYSTEM

A. Evaluation Environment

The evaluation was conducted in lab environment. Two plastic containers were used: one as the upper water tank, WT and another as the water reserve, WR as showed in Figure 1. According to the working principle of the system, the system had to take actions depending on the water level in the both tanks i.e.: when water in WT is <= 10% and water in WR was >= 40%, then the AP should be started to fill up WT up to 30%. So, the container which was used as WR, was marked as 100%, 80%, 40% and 0% so that the working procedure could be easily monitored. For the WT container, there were traces to point 100%, 30%, 10% and 0% water height as well. The rest of the components were connected as they were demonstrated in Section III.

B. Evaluation Procedure

The system was initiated and started to collect data for the cases which have been described as working principle. A total of 20 trials were considered for each case and the response of the system was monitored which it was supposed to generate. From the responses, the number of success trials and delay for each trials were assembled separately. From the acquired values, the success rate percentage and average delay for each case were calculated. All the extracted data were compiled in Table I. Finally, total average delay of 1.0349 seconds and total success rate of 90% were determined for any case.

C. Data analysis and Findings

The study data was synthesized and analyzed to assess the system's *reliability* and *availability*.

a) Reliability- the results showed that the system responded well for different cases (see Table I). For the specific trials the delay may vary, but the average delay was not more than 1.26 seconds for each case. The system showed a total average delay of 1.0349 seconds for any response. The percentage of success rate to execute each condition varied from 80% to 95%. Thus, the system showed good performance in terms of the reliability.

b) Availability - the evaluation results showed that the system was consistently active (available) for the entire duration of conducting the experiment (see Table I). Though the system responded late for some cases, it was not switched off automatically in any case. In case, if there was no water usage for a long time, the system was still switched on and whenever there was any indication of water usage and WT needed to be filled up, the system started automatically to pump water to WT.

Moreover, a traditional water pumping system generally includes some common components i.e: water tank, water

Table II
APPROXIMATE COST TO DEVELOP THE SYSTEM

Equipment Name	Quantity	Cost in USD	
		Prototype System	Concrete Implementation
Arduino Uno	1	6	6
Water Pump	1	6	70
Potentiometer	7	2	2
Relay Switch	2	1	1
Circuit Cover Box	1	-	5
	Total Cost	14$	85$

pump and water passing line (pipe). Thus, except these items, the tentative cost to develop the proposed prototype system and the cost of concrete implementation has been presented in Table II.

This shows that only $85 (except the cost of water tank, main water pump and water passing line) will be required to develop the intelligent system while the prototype system required only $14. These cost data indicates that the proposed system is cost-effective with respect to its expected benefits regarding time, labor and water loss in the capital (Dhaka city) of Bangladesh.

V. Conclusion

Supplying adequate water is one of the crucial challenges to meet in major cities like Dhaka, in modern times. The major challenge of this model was to develop an intelligent cost-effective system so that it can be useful to the citizens of Dhaka. Thus, this article presented the design and development of an automated water pumping system. A set of logical conditions were integrated to develop the system so that the proposed water pump can work intelligently. The construction cost of the proposed system is very low and it requires a small amount of electricity to run the system. The system works automatically according to the logic applied in it and so no manual monitoring is required. The evaluation study and expenditure data showed that the system is reliable, available and cost-effective. In case of the implementation in real life, considering different aspects of using the proposed system like- per unit and maximum charges of water and electricity, efficiency of this system against the existing systems, electricity tariff etc., this simple system will be able to reduce the actual cost and effort. Future work may focus to implement the concrete version of the prototype model and then comparing this system with the existing systems.

***Abstract*— With the advancement of wireless technology, wireless based automation is playing an important role in human life. Home automation is a house or living environment that contains the technology to allow devices and systems to be controlled automatically. The remote control is useful to keep home comfortable for general people and to support the elderly and physically impaired people. In this paper, we propose a system that will be able to control household appliances remotely. The system provides ON/OFF voice response via the speaker according to the user command on the appliances. We divide the overall system into two modules. One is a transmitter or Bluetooth remote and another one is receiver or relay module. Bluetooth remote consists of several push buttons to control the household appliances. The remote and relay modules are configured as master-slave to communicate between the modules. To produce the voice response, the recorded voices are store in micro-SD card. With the voice response, the user can easily understand which household appliance is controlling at a particular time. We implement the system to validate its applicability. Additionally, we compare and analyze statistically the general people's impression of the proposed system over a traditional system.**

Keywords*— *Home Automation, Bluetooth Network, Remote Control, Relay Module, Voice Response, Home Appliances.

I. INTRODUCTION

We are living in an era of advanced technology, where every part of our daily lives is related to the science of craft in one way or another. Housing and lifestyle have been impacted by modern technology such as automated door locks, security cameras and lighting control, which makes our life much easier, organized and safer. Bluetooth technology is one of the most popular wireless technology used to control the household devices wirelessly. Nowadays, home automation is one of the major applications of Bluetooth technology. Operating over globally available unlicensed frequency (2.4GHz), it can link digital devices within a range of 10m to 100m at the speed of up to 3 Mbps depending on the Bluetooth device class [1].

Nowadays human beings are addicted to use modern equipment specially in home environment. Conventional wall mounted switches located in different parts of the house makes it uncomfortable for the user to go near them to operate. It becomes more difficult for the elderly or physically impaired people to use it. The home automation system is used to control the indoor and outdoor lights, fans, ventilation, air conditioning, electrical and electronic appliances and so on using a control systems. Various types of home automation systems like Bluetooth controlled [2-7], internet controlled [8-12], Android-based [13-16], Infrared (IR) remote controlled [17] are available at present. It helps people to reduce work and better household management.

Bluetooth and Android-based home automation system consists of a receiver end at which Arduino board and Bluetooth device are interfaced [2-7]. As a transmitter, the cell phone application is used to send ON/OFF command signals to the receiver. Thus, by receiving these commands from cell phone application given by the user the appliances can be turned ON/OFF remotely. Internet of Things (IoT) technology is used to control various electrical appliances remotely over the internet [8]. The smartphone android application with user configurable GUI front end is used for the real-time scenario.

In IR remote controlled home automation system, the remote sends commands to control home appliances. After receiving the signal from the remote, Arduino sends the related signal to relays which are responsible for switching ON or OFF of the home appliances through a relay driver [18].

Usually, it is difficult for visually impaired people to operate the android phone and IR transmitter which require line of sight between transmitter and receiver. So, the above systems are not easily applicable for elderly and impaired people and need a better home automation system that easily operable by the user. In this paper, we propose a home automation system that controls the household appliances by Bluetooth remote and produces the corresponding voice response from the receiver of the appliances. By the voice response, the impaired people can easily make sure that the appliance is active or not now, according to the user command.

This paper consists of six sections. Section I discusses the introductory concept of the proposed system. Section II discusses the recent works on wireless home automation system. The proposed system designing procedure is discussed in Section III. Section IV discusses about the implementation and cost analysis. Section V discusses about the system evaluation results. Finally, Section VI concludes the works and discusses some direction of future works.

II. RELATED WORK

In literature a number of remote-controlled home automation systems have been found. For example, Piyare et al. [2] provided full function remote control home automation system in which Arduino Bluetooth (BT) and cell phone communicate wirelessly using Bluetooth technology. The home appliance was controlled by using Symbian OS cell phone application and the Arduino Bluetooth board was connected to these appliances. Java-based application cannot support the Symbian OS cell phone and it is only supporting the python language scripts. Note that nowadays mostly smartphone applications are developed in Java. Like this, another study [3] presented a home automation system using Bluetooth and android application. It was not feasible to control more than 4 home appliances and it was designed to control only for 4 lights.

An internet-based smart home automation system [4] proposed and implemented that can be controlled remotely upon user authentication. Another internet-based home automation system [10] is designed for the rural environment using Raspberry Pi (RP) and web page. After login in the webpage, the user can control the appliances using webpage via the internet. However, using this system user can control the appliances from anywhere through the internet but the user is not sure that the appliances are controlled and it cannot use the impaired people.

In [5] a low cost and user-friendly remote-controlled home automation system is designed using Arduino board, Bluetooth module, smartphone, ultrasonic sensor, and a moisture sensor. A smartphone application is used in this system to control the household appliances and monitor the sensor values. In this system Bluetooth wireless connection was established between smartphone and Arduino Uno. The smartphone cannot operate by the visually impaired people, so this system is not applicable for disable people. We proposed a system for visually impaired people using Bluetooth network. The impaired people can easily operate the Bluetooth remote control of the proposed system. By pressing the button of the remote, the visually impaired people can control household appliances.

The infrared remote can be used for this proposed system, but the coverage area of infrared is sort than Bluetooth and it required line of sight. Thus, the Bluetooth network-based remote-controlled home automation system is proposed in this paper.

III. SYSTEM DESIGN AND WORKING PRINCIPLE

A. *Proposed Home Automation System*

The proposed system has two main parts hardware and software. The hardware part consists of some electronic devices. Software part consists of an Arduino integrated development environment (IDE). The overall system divided into two sections.

1. The transmitter or Bluetooth remote.
2. Receiver or relay module.

The transmitter or Bluetooth remote consists of a keypad, microcontroller, and a HC-05 Bluetooth module. The keypad in transmitter consists several push buttons. The receiver or relay module consists of a microcontroller, a HC-05 Bluetooth module, 4-channel relay module, micro-SD card reader module and speaker, etc. The number of channels in the relay module depends on how many appliances are controlled.

Fig. 1 illustrated the block diagram of proposed home automation system.

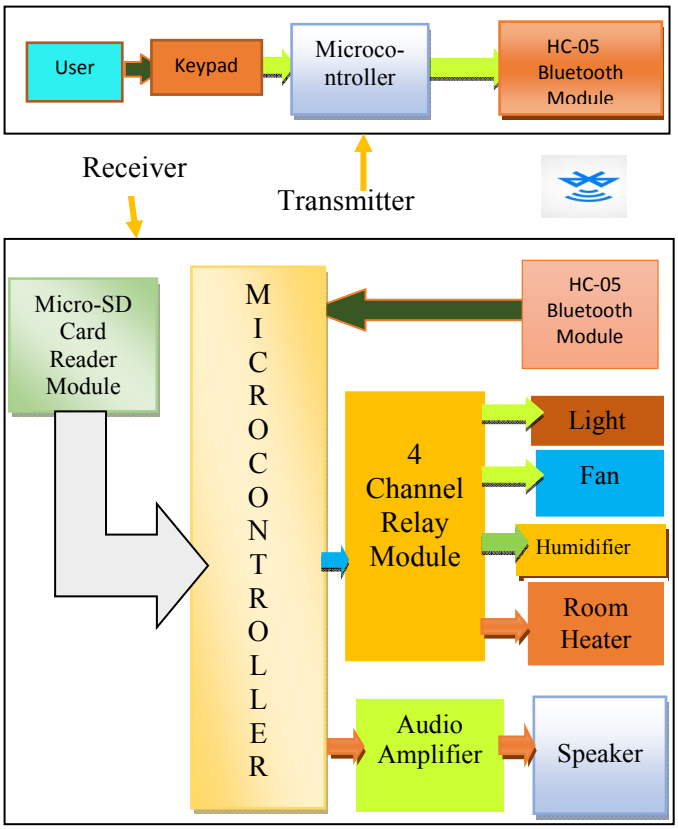

Fig. 1. Block diagram of proposed system.

B. *Hardware Components*

The following components are required to design the overall system.

- Arduino Uno
- Push button
- HC-05 Bluetooth module
- 4-channel relay module
- Micro-SD reader module
- Micro-SD card
- Speaker
- LM 386 audio amplifier.
- A Power source and DC adapter

C. *Master-Slave Configuration of HC-05 Bluetooth Module*

HC-05 module is an easy to use Bluetooth SPP (Serial Port Protocol) module, designed for transparent wireless serial connection setup. Before the design of the proposed system,

we need one HC-05 Bluetooth module as master and another is a slave to communicate between transmitter and relay control receiver device. HC-05 Bluetooth module has two modes of operation, Command Mode where we can send attention (AT) commands to it and Data Mode where it transmits and receives data to another Bluetooth module. The default mode is Data Mode and works as a slave. To configure the master mode, we need to change the default configuration. Using the AT command, we can change the default configuration. To set the modules into Command Mode, we need to connect the KEY pin high before applying power to the module.

D. Design of Transmitter or Bluetooth Remote Circuit

The transmitter or Bluetooth remote circuit is illustrated in Fig. 2. It consists of a master HC-05 BT module, eight push buttons and power source with Arduino Uno. In this circuit, the BT module transmits different signals according to pressing the push button. Each push button has a specific digital signal. These push buttons are numbered from left to right, button 1 is used to turn ON the light, button 2 is used to turn OFF the light. Similarly, button (3, 4), (5, 6), (7, 8) are used for fan, humidifier and room heater respectively for ON and OFF. The system could be extended for any numbers of appliances by increasing number of push buttons.

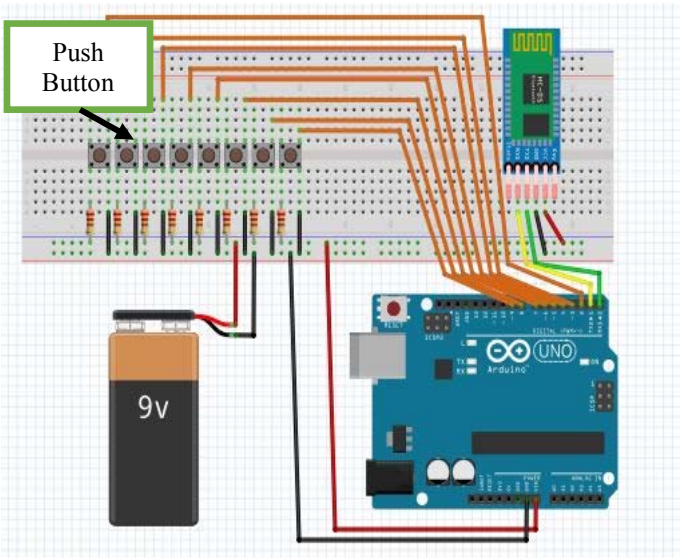

Fig. 2. Transmitter or Bluetooth remote circuit.

E. Design of Receiver or Relay Module Circuit

Circuit diagram of the receiver or relay module is illustrated in Fig. 3.In the receiver HC-05, the BT module acts as a slave, so it receives the transmitted signal. According to the transmitted signal, the channel is ON or OFF of the 4-channel relay module. The household appliances are connected to the relay channel. The voice response section is one of the parts of the receiver circuit. It consists of LM386 audio amplifier, Micro-SD card reader and speaker.

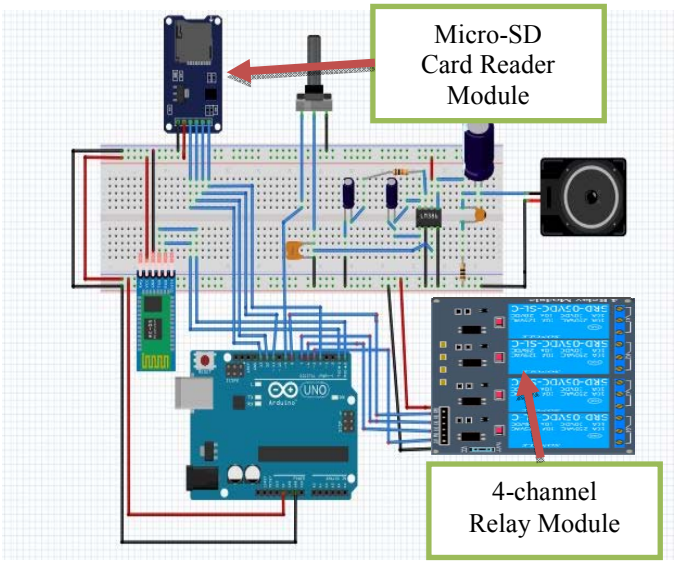

Fig. 3. Receiver or Relay control circuit.

IV. IMPLEMENTATION

A. Experimental Setup

The designed transmitter or Bluetooth remote is illustrated in Fig. 4. The user can control the household appliances using the module within the Bluetooth communication range. The device is portable, so the user can carry easily. The use of this device is simple. When a push button is pressed, it transmits a digital signal via HC-05 master Bluetooth module to the relay module to control the household appliances.

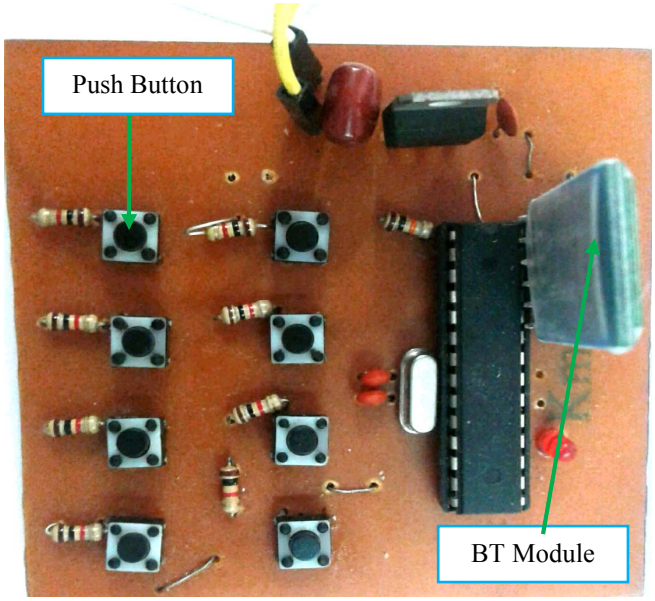

Fig. 4. Transmitter or Bluetooth remote.

The receiver or relay module is illustrated in Fig. 5. We use four appliances (light, fan, humidifier, and room heater) and show with four lights for primary implementation.

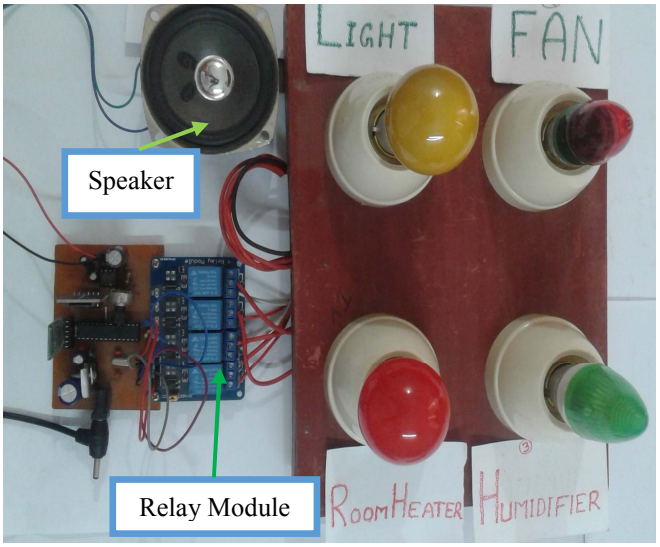

Fig. 5. Receiver or Relay module.

In the relay module device, the pre-recorded voice response is provided via the speaker. For example, when the user presses the button 1 (note button 1 for turn on light), then voice response gives as "Thank you, you on the light" two times repeatedly. Similarly, the response will be provided for fan, humidifier and room heater, when button 3, 5 and 7 are pressed respectively. When a user presses the button 2, then voice response gives as "Thank you, you off the light" two times repeatedly. Similarly, the response will be provided for a fan, humidifier, and room heater, when pressing button 4, 6 and 8, respectively to off the devices. Table I summarizes the voice response of all the 8 buttons.

TABLE I. SWITCHING SUMMARY OF THE FOUR HOUSEHOLD APPLIANCES

Name of Appliance	Button Number	Work	Transmitted signal	Voice response From receiver
Light	Button 1	ON	a	Thank you, you on the light
	Button 2	OFF	b	Thank you, you off the light
Fan	Button 3	ON	c	Thank you, you on the fan
	Button 4	OFF	d	Thank you, you off the fan
Humidifier	Button 5	ON	e	Thank you, you on the humidifier
	Button 6	OFF	f	Thank you, you off the humidifier
Room heater	Button 7	ON	g	Thank you, you on the room heater
	Button 8	OFF	h	Thank you, you off the room heater

B. *Cost Analysis*

We summarize the used equipment and cost to design the system in Table II. It is seen from the table that the designed home automation system is cost effective and economical. The cost of this system depends on the setup environment. In Table II we show the only cost to control four household appliances.

TABLE II. COSTS OF EQUIPMENTS

Name of Equipment	Quantity	Cost (BDT)
Microcontroller	2	2x175=350
HC-05 Bluetooth module	2	2×250=500
SD card reader module	1	240
4-channel relay module	1	250
Speaker	1	50
AC to DC adapter	1	75
Switch, Battery and other parts	-	700
Total cost	-	2165

V. SYSTEM EVALUATION

Our system is evaluated in two ways: Firstly, we conducted experiments to measure the effectiveness of the system. We control our home appliances under different distances from the receiver or relay module in real house environment. Secondly, we conducted an experiment with general participants to verify the usefulness to control the home appliances through evaluating their impression about the system.

A. *Percentages of Success*

Usually, the coverage area of the Bluetooth device is 10-100 m long from the receiver [1]. To measure the coverage area of the proposed system, we take the percentage of success in controlling the home appliances in different distance from the receiver or relay module. There is no line of sight between transmitter and receiver. Table III summarizes the result of the experiment.

TABLE III. MEASUREMENT OF COVERAGE DISTANCE

Distance of the Remote from Receiver (m)	No. of attempt	No. of Successful attempt	No. of failure attempt	Percentage of Success
2	15	15	0	100%
5	25	25	0	100%
8	25	21	4	84%
10	25	17	8	68%
12	25	10	15	40%
15	20	0	20	0%

The table shows that when the remote is used within the 8 m from the receiver, the proposed system is robust to control the home appliances. But, when the distance of the remote

from the receiver increases by 2 m then the percentages of success to control the home appliances drastically reduced to around 68%. When the remote was around 12 m away from the receiver then the performance of the proposed system is not satisfactory to control the home appliances. Thus, we can conclude from the above experiment that even though the coverage area of Bluetooth is 10-100 m, but the proposed system can robustly control the appliances within the distance of 8 m from the receiver.

B. System Evaluation with Participants

We conducted an experiment by involving general participant to verify the effectiveness of the proposed system.

1) Participants: In the experiment total of 32 unpaid participants (all are male students) were participated at the University of Rajshahi (mean age 22 years).

2) Experimental Case: In order to evaluate the effectiveness of the proposed system in controlling home appliances using Bluetooth network-based remote system, we measure the impressions of the participants about the proposed system and also measure the impressions of participants of the traditional system. Every participant used the proposed system and traditional system in controlling the home appliances in a living room environment.

a) With Proposed System (Sys-1): In order to control the home appliances, participants use the proposed system (explained in Section III).

b) With Traditional System (Sys-2): In order to control the home appliances, participants use traditional switchboard which is not remotely operable but fixed on a wall. In this case, to control the home appliances, participants should move to the swtichboard physically to control their home appliances.

3) Measurement: In the experiment, we evaluate the particiapnts' impression of both systems. We asked participants to fill out a questionnaire for each method (after using the systems). The measurement was a simple rating on a Likert Scale of 1 to 7. The questionnaire had the following three items:

- **Q1**: Did you feel that the system is convenient in controlling your home appliances?
- **Q2:** Did you feel that the system is helpful for elderly and physically impaired people in controlling their home appliances?
- **Q3**: How satisfied are you with the system in controlling your home appliances?

C. Results

The experiment was performed in a within-participant design, and the order of all experiment was counterbalanced. We conducted the repeated measure analysis of variance (ANOVA) for all measures

1) Impression: The mean (M), standard deviation (SD), *F*, *p-value*, and η^2 of the questionnaire measures for both system are shown in the Table-IV.

Table-IV
PARTICIPANTS IMPRESSION FOR QUESTIONNAIRES

	Q1		Q2		Q3	
	Sys-1	Sys-2	Sys-1	Sys-2	Sys-1	Sys-2
M	6.6	5.38	6.41	3.47	6.13	4.63
SD	1.28	2.56	1.22	4.06	0.37	3.27
F(1,31)	10.88		43.7		21.06	
p-value	0.00245		0.0000002		0.00007	
η^2	0.166		0.457		0.242	

For questionnaire **Q1** (Table-IV), the difference between the two systems (Sys-1, and Sys-2) was statistically significant ($F(1,31) = 10.88$, $p < 0.01$, and $\eta^2 = 0.166$). Thus, participants feel that Sys-1 is more convenient over Sys-2 in controlling their home appliances.

For questionnaire **Q2** (Table-IV), the ANOVA analysis also shows a significant difference in considering Sys-1 over Sys-2 for the elderly and physically impaired person in controlling their home appliances ($F(1,31) = 43.7$, $p < 0.01$, and $\eta^2 = 0.457$). Thus, participants feel that Sys-1 is helpful over Sys-2 for elderly and physically impaired people in controlling their home appliances.

To find the impression between the two systems for questionnaire **Q3** (Table-IV), we also performed the ANOVA analysis on the Likert scale. The difference between the two systems (Sys-1, and Sys-2) were also statistically significant ($F(1,31) = 21.06$s, $p < 0.01$, and $\eta^2 = 0.242$). It reveals that participants are satisfied in using our proposed system (Sys-1) in controlling their home appliances.

Thus, we conclude that the proposed system (Sys-1) is more convenient and effective than the traditional system (Sys-2) for controlling home appliances. It can also be stated based on the above analysis that our proposed system is also helpful for elderly and physically impaired people to control their home appliances.

VI. CONCLUSION AND FUTURE WORK

In this paper, we have proposed the design and implementation of a low cost and user-friendly Bluetooth network-based home automation system, to control the home appliances remotely. The proposed system is implemented to control four appliances including light, fan, humidifier and room heater. The number of household appliances can increase by increasing the number of push buttons in the transmitter. The system is better to use for ON/OFF switching the appliances remotely without internet connection. The system is easy to operate by elderly and visually impaired people than other remote-control home automation system. Visually impaired people cannot run the android phone easily. The elderly and visually impaired people can easily control

the home appliances by pressing the push button of the remote module.

Future works can be focused on enhancing the performance of the system. The Bluetooth wireless communication system can be replaced with another wireless communication system to cover large areas.

***Abstract*—Bangladesh railway system mostly relies on manual maintenance system. At present, a trolley car is used in which people go in person to examine the railway system depending only on their vision. Mostly, these checking include detection of rail line cracks and obstacles, existence of sleepers in the proper places etc. However, the inadequacy of this kind of maintenance system is one of the vital reasons of railway accidents. The current procedure is also time consuming and costly. Besides, one of the leading causes of railway accidents is attributed to human error which can be reduced through automation. This paper attempts to improve the railway maintenance system and convert this into an automated one. Here, we are introducing a sensor based arrangement which reveals problems like surface crack, unaligned rail lines, obstacles on the railway and also inspects the correct position, presence and absence of the sleepers with the convenience of sending the location and distance to the proper authority.**

***Index Terms*—Automation, Bangladesh railway, Obstacle detection, Railway maintenance, Sensor based system**

I. Introduction

In Bangladesh, railway is a very important domestic transport that links the length and breadth of the entire country. It contributes to the economic development of the country in a large way [1]. In our country, railway transport is most widely used and commonly used and cheapest mode of transport for the local people.

Though Bangladesh Railway is stated as one of the safest transportation system, its service condition and improvement status may not go with the statement [2]. Since 1972, Bangladesh has been going through a large number of train accidents. These days we can observe frequently in news that, railway accidents are rather common. The approximate number of accidents from 2001-2010 was about 5938 [3]. Among these, most of the accidents were for the derailment of train [4]. About 5461 train derailments were taken place from 2001-2010, which is approximately 92% of the entire incidences. These huge rate of derailments involve significant economic losses, interruption to services and obviously the safety risk of passengers [3].

The rapid increase of railway accidents have almost turned the railway safety status into impoverished state but the taken actions are not up to the mark. It has always been reported and claimed after an incident that main drawbacks behind this reason is the lack of obligation and the inappropriate management in operating system by the authority. Without proper steps, no solution will appear and the problems will last forever.

Analysis of train derailments in Bangladesh railway, shows that 72.6% (2195 out of 3022) of derailment was occurred because of the defects of track when 15.5% due to human failure, 7.1% due to vehicle failure, 4.8% due to combined factors and remaining 0.1% due to others [5]. This is the reason to automate the train maintenance system over the manual and human dependent present one.

From the above statistics, it is again clear that among the causes of railway accidents, one of the vital reasons is human error. The defects of track are difficult to understand manually. Generally in present railway system, the Track-men walk along miles of railway lines almost eight hours per day carrying 20-25 kg of monitoring equipment, in all atmospheric conditions. They have to check that the track bed under the sleepers is packed correctly or not, fix the cracks and sleeper damage, make sure of the nut-bolts and joints, and check on the clips that hold rails to the sleepers. This method of review is not so dependable because most of the time, those cracks can not be found by the Track-men. Also, this type of supervising system is not acceptable because of slowness and absence of conciseness, as the observer has to recognize the critical situations for a long period.

Our present model is a minor attempt to find out a way to make the maintenance system automated. In this paper we will describe a method to detect the surface and side cracks of railway. As well as we will detect fault in sleeper and obstacle in railway with latitude and longitude of that location. This system is designed in such a way which will perform as a railway safety monitoring system. Though this model will not serve the purpose of actual commercial use, but it is sufficient to show the way through which we can proceed to make the railway maintenance system completely automatic which will go through rail track and will detect the cracks and defects on the sleepers and hence preventing the rail accident.

The rest of the paper organization is as follows: We have covered the relevant researches in this field in the section II. In section III, the conceptual design has been discussed. In section IV, the technical implementation and work-flow have been demonstrated including real prototype images. Finally,

TABLE I
COMPARISON OF OUR SYSTEM WITH OTHER APPROACHES

Author	Paper Title	Paper Proposal	Our System
Sedat Ying Li et al [6]	Railway Fastener Inspection by Real-Time Machine Vision	In this paper, they have presented a real-time railway fastener detection system with the use of a high-speed laser range finder camera based on Pixel Similarity-Based Approaches and Histogram-Based Similarity Approaches with complex calculations	Our proposed system is simple to implement and the calculations that we have implemented are easy to understand.
Dogru et al [7]	Rail Component Detection, Optimization, and Assessment for Automatic Rail Track Inspection	Developed a group of image and video by vision-based analysis which also included distance measurement instrument for better precision and efficiency to detect significant rail modules for example ties, tie plates, and anchors automatically.	We put an automated sensor based system which can detect surface crack, unaligned rail lines, obstacle and additionally inspect the accurate position, presence and absence of the sleepers in context of Bangladesh. Also it can send the location of the defected position with distance from the station to proper authority.
Salzburger et al [8]	In-motion ultrasonic testing of the tread of high-speed railway wheels using the inspection system AUROPA III	Their Proposed system implements the examination of the whole boundary of the tread while the train passes over stationary ultrasonic probes at speeds of up to 15 km/h which only solves the problem related to the circumference of the tread.	We propose an automated railway maintenance system which will be able to detect four different most common defects in railway.

with some limitations described in section V, section VI concludes the paper.

II. LITERATURE REVIEW

Many approaches have been made for railway quality inspection. Fastener inspection is a part of general railway inspection. Fasteners are used for creating non-permanent joints in rail line and sometimes which can be damaged. Generally, the inspection to check the joints is done manually which is time consuming and crucial mistakes could be made. But by a real-time railway fastener detection system which

uses a faster 3-D camera placed under a railway carriage, this problem has been solved [6]. In another analysis, a real-time automatic vision based rail inspection system was presented, which performs inspections at 16 km/h with a 20 fps frame rate [7]. Detecting wheel tread damages is important for the security of the whole train. To detect crack-like defects in the tread of railway wheels AUROPA III is a new ultrasonic based inspection system [8]. This system enables the whole circumference inspection of the tread while the train passes over stationary ultrasonic probes at speeds of up to 15 km/h.

A number of processes have been used to perform fault detection in railway vehicles. These include advanced filtering, system identification and signal analysis methods. By few researches, the problem was solved by using track-mounted sensors for this kind of monitoring purposes [9]. Another system was developed which includes: a position system, an unmanned self-propelled vehicle, a sensor and a control system [10]. The unmanned automotive vehicle is adapted to travel on a railway track ahead of the train and has a sensor which is configured to detect an unfavorable railway condition. The positioning system is built to determine the position of the self-propelled vehicle. The control system in communication with the sensor and the train, where in the control system communicates the adverse railway condition to the train.

Elastic wave analysis for broken rail detection has also been done [11]. In that analysis, the process is based on elastic guided wave propagation through the rail. Broken rail detection is possible by using an impact device or energy propagating from the train wheel in contact with the rail. There has been a long debate among train control professionals about broken rail detection: where it is necessary and how it is achieved. There has been little research in terms of the actual practical application of new technology or risk mitigation approaches since conventional track circuits have been utilized to detect broken rails [12].

Some years ago, two railway inspection trains (RIT) already equipped with ultrasound, had additional advanced eddy current techniques installed. Recently, a new RIT was equipped with a system that was designed, from the beginning, to employ a combination of these two techniques for non-destructive rail inspection [13]. The eddy current technique has been developed to enable identification of rolling contact fatigue (RCF) faults. The ultrasound process is aimed at measurements in the rail bulk volume, which are not feasible using the eddy current technique. Another development of non-destructive techniques (NDT) for the in-service inspection of railroad wheels and gauge corners was the main activity of the NDT division VIII. 4 at BAM over the last 2 years. For such various components, two different inspection techniques were chosen to fulfill the end-user requirements. Firstly, the inspection of the wheels rim and disk should be carried out without dismantling the wheels and using ultrasonic techniques [14]. On the other hand, the inspection of the railroad track surface at a train speed of about 70 km/h should be guaranteed using eddy current processes. Eddy current application focused

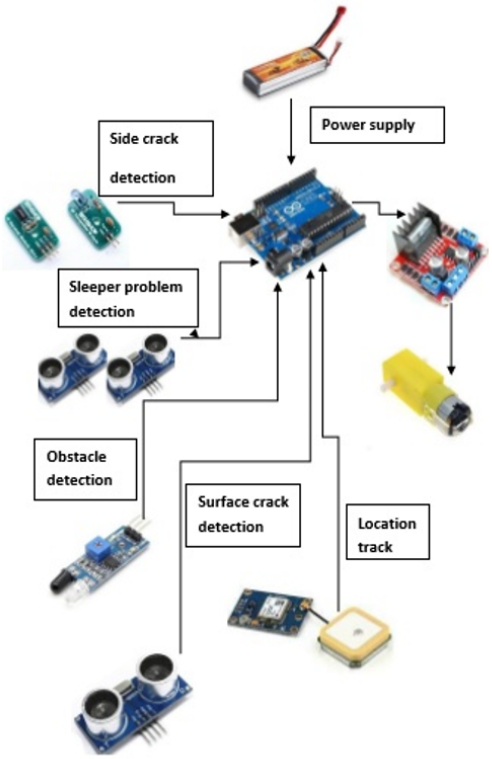

Fig. 1. System architecture of our proposed system

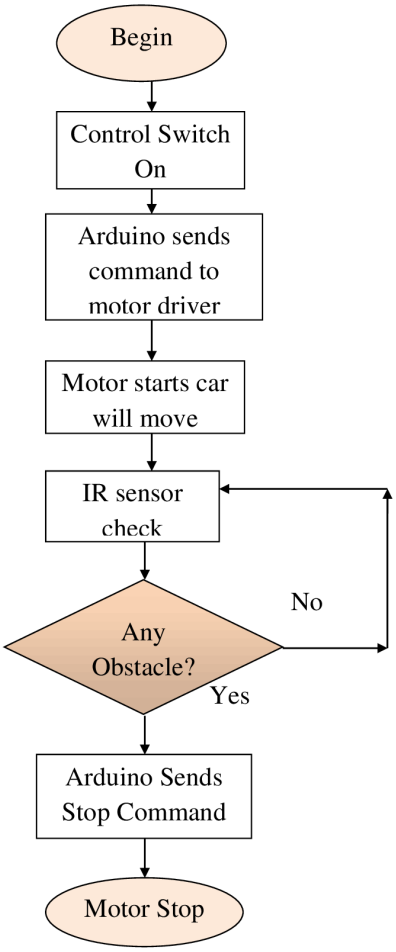

Fig. 2. Work flow of obstacle detection

mainly on the detection of head check defects occurring at the gauge corner of the rail.

The aim of a paper was to present a new vision based inspection technique for detecting special Rolling Contact Fatigue (RCF) defects that particularly occurs on rail head surface, meanwhile, an automatic detecting system is implemented, which consists of pre-processing, defect locating, defect identifying and post-processing subsystems [15]. To realize the defect locating sub-procedure, a simple and fast algorithm has been proposed, which adopts geometrical analysis directly on a gray-level histogram curve (the first-order statistical texture property) of the smoothed rail head surface image.

According to the researches so far related to railway maintenance system the major difference of other approaches and ours is the detection of slippers correct position and defect in slipper. Our proposed system is mainly based on different type of sensors which is less costly than many other proposed systems. In Table I we have shown a comparison between our approach and three relevant existing approaches. This comparison was based on only three approaches as they were pertinent.

III. Conceptual Design

In this section, we will describe about the main concept of our proposed maintenance car. Our car will detect different types of problems in railway system automatically. After detecting the problems, we will save the location of the problematic area into a local storage system. In addition, it will notify the proper authority so that problems can be repaired in time to avoid accidents. A system architecture of our maintenance car is given in Fig. 1. The main features of our system have been described below:

1. **Obstacle Detection**: Automated maintenance car will detect if there is any obstacle on the railway. Obstacles are one of the causes of train accidents. So, we will use a procedure which will detect obstacles on the railway and track the location. The flow of this feature is shown in Fig. 2.

2. **Surface Crack and Sleeper Problem Detection**: It detects the surface cracks of the railway which is one of the causes of train accidents. Here, we use a procedure which will continuously detect usual distance of the railway surface. When the measured distance is greater than usual distance it will detect the surface crack and save the location to database. It uses the same procedure for sleeper problem detection. It will be able to detect if there is any sleeper missing problem or sleeper alignment problem and will save those locations. The flow of this feature is shown in Fig. 3.

3. **Side Crack Detection**: It will detect side cracks and track

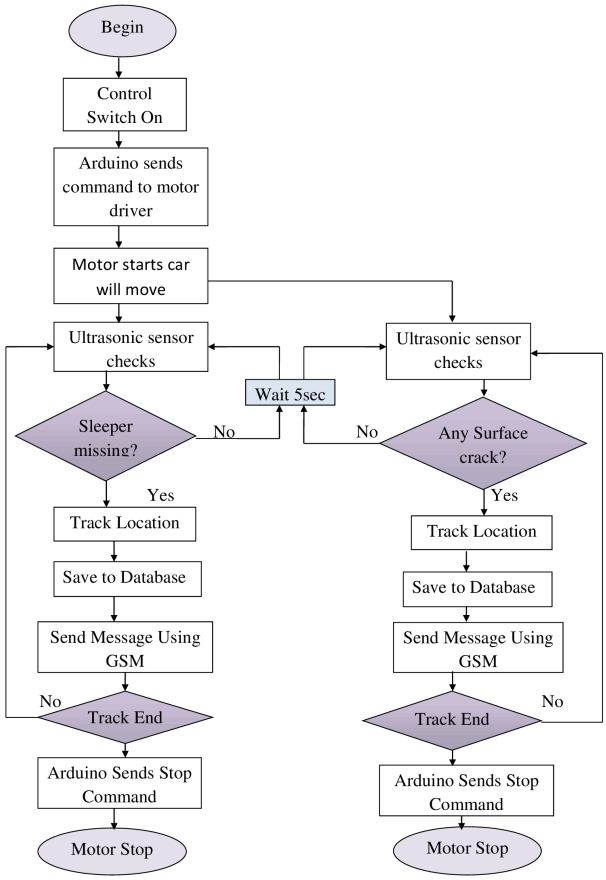

Fig. 3. Work flow of sleeper fault and surface crack detection

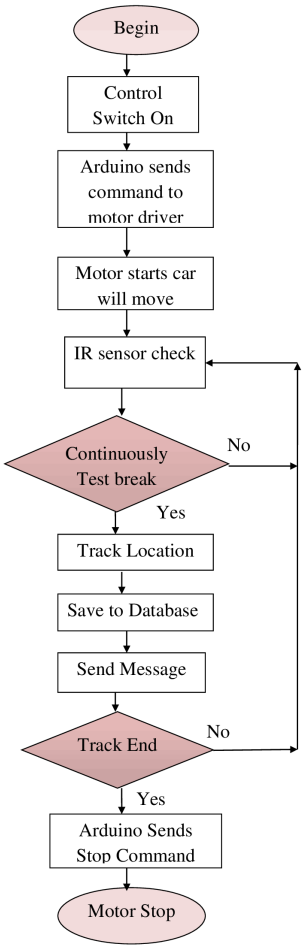

Fig. 4. Work flow of side crack detection

those locations. Here, we use a procedure which will receive a signal if there is any side crack, then it will save the location to the database. The flow of this feature is illustrated in Fig. 4.

4. **Storing Information**: Another important feature of our maintenance car is that it will be able save all the problem specifications along with location in a local storage, sd card.

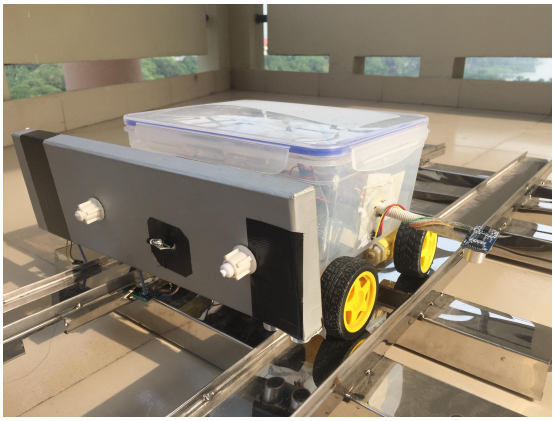
IV. Implementation and Work Flow

The proposed system is implemented by IR sensor, Ultrasonic sensor, GPS, SD Card and Motor Driver Module which is demonstrated in Fig. 5 in the following manner:

IR Sensor module: Our maintenance car will detect if there is any obstacle on the railway with the help of IR sensor. Here, both the receiver and transmitter of IR sensor are set on the same side. The sensor will continuously send an infrared signal and when it gets any obstacle, the signal is reflected back to the IR receiver that captures the signal detecting the object.

IR Receiver and Transmitter Module Pair: Our maintenance car will detect side cracks with the help of IR sensor module. Here, IR transmitter and IR receiver are set on the opposite side. If there is any side crack, IR receiver will receive signal from IR transmitter. Thus it will be able to detect the side crack.

Ultrasonic Sensor Module: Our maintenance car will detect surface crack on the railway with the help of ultrasonic sensor. Ultrasonic sensor module can measure the distance to an object by using sound wave. The sensor of the maintenance car will continuously detect the distance of the surface of the railway and whenever the distance of the surface is greater than the usual distance it will be able to detect the crack of the surface.



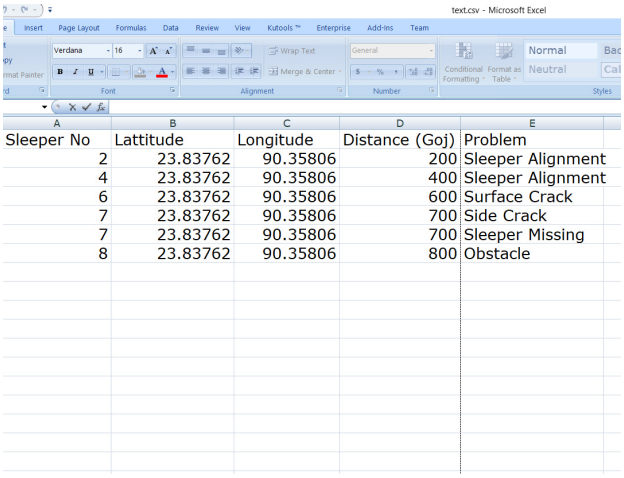


Fig. 5. Prototype of the proposed system

Sleeper No	Lattitude	Longitude	Distance (Goj)	Problem
2	23.83762	90.35806	200	Sleeper Alignment
4	23.83762	90.35806	400	Sleeper Alignment
6	23.83762	90.35806	600	Surface Crack
7	23.83762	90.35806	700	Side Crack
7	23.83762	90.35806	700	Sleeper Missing
8	23.83762	90.35806	800	Obstacle

Fig. 6. Data Storage

Ultrasonic Sensor Pair Module: Our car will detect the problem of sleepers with the help of two ultrasonic sensors. Here, we use the same feature of ultrasonic sensor as in surface crack detection but in a different way. Ultrasonic sensors will sense the distance of the sleepers continuously after a certain period of time when it is supposed to detect a sleeper. If the distance of both the ultrasonic sensors are same it will consider that there is no problem with the sleeper. But if the the distance of the ultrasonic sensors differs it will consider it as slipper problem.

GPS and SD Card Module: Whenever, it finds any error it will work as its principle and track the location with the help of GPS and save the location along with problem specication to the local storage (SD card). Here, we are saving the error specifications along with location in .csv file, shown in Fig. 6.

Motor Driver Module: Here, with the help of motor driver we are driving our car and controlling speed along with time synchronization.

V. Limitations and Future Plan

The implemented maintenance car has some limitations. It is not capable of detecting all types of error. It needs some additional maintenance cost. It can not be controlled remotely and if there is any problem with the maintenance car during automated investigation, it can not be detected remotely. The system can be improved in future by detecting other types of faults of railway and controlling the maintenance car remotely. The maintenance cost can also be decreased in future.

VI. Conclusion

After a number of investigations, it has been found that the existing railway maintenance system is infrequent and time consuming as well as costly. Another cause of railway accidents is human error for manual maintenance system. Our proposed system is mainly based on the use of different type of sensors which is less costly than many other proposed systems.

We have tried to improve the existing system through our project. Here, we have improved our system by converting the system into an automated one, tracking locations of specific problems with the help of GPS and reducing inspection time, human error. We hope Bangladesh Railway will be benefited through our proposed system in a large manner.

***Abstract*—Home automation based on Internet of Things (IoT) is getting huge attention of mass people in recent years. Smart home eases and secures the management of the home appliances. This paper presents a low cost and reliable smart home system that assists the users to manage home appliances without the need of their physical presence. The proposed system includes smart door lock system using Radio Frequency Identification (RFID) card and password. It can store and display information of temperature & humidity of a home, and notifies the users of switching on/off time of light, fan and other home appliances using embedded micro-web server and an IoT platform. The user can also control the light intensity and fan speed based on LDR and temperature sensor values respectively. The system includes gas leakage & fire alarm. It has leakage gas removing & fire extinguishing facility and SMS notification system using IoT platform. The system uses real IP and RESTful API for controlling, monitoring and accessing the home appliances remotely from anywhere in the world using Android based smartphone app or web app. This system is user friendly and energy efficient.**

Keywords—IoT, PaaS, Home automation, Micro-web server, Teleduino, Altair SmartCore, RESTful API, Arduino.

I. INTRODUCTION

Internet of Things (IoT) is one of the mostly talked research topics in the recent years. IoT based home automation system is getting popularities day by day. Home automation is the controlling of the different home appliances using smart devices anywhere in the world without the need of physical presence in the home. Smart home system is very beneficial in everyday life as it saves electricity and reduces worries for home security of working people. Due to the secure, easily controllable and monitorable features, advanced home automation system design has become a core interest for many researchers.

Nowadays communication has become much easier due to the increased use of smartphone and laptop. People uses internet more than phone calls and SMS to communicate with each other. It is easy to process huge data faster and easier with the help of internet. Every day millions of devices are connected with internet in homes, schools, workplaces, and vehicles for helping people to live and communicate in a smarter way which is needed to analyze and translate via a gateway device. IoT platform can handle this kind of work. IoT platform is an important component of IoT that provides valuable application specific services in many application domains. Many kinds of IoT platforms are available nowadays [1] [2]. Platform as a Service (PaaS) is one of them, where the web developer has to take care only about the functionality of his application. During a development, he can use the API provided by the company to access important features of the PaaS, such as performing database operations, or managing users of his application [2]. An IoT platform is an integrated service that offers the user the things he needs to bring in online. It is capable of supporting millions of simultaneous device connections and easily allows the user to configure devices for machine-to-machine communication. In this paper, Altair SmartCore IoT platform [3] has been used which is based on the PaaS base IoT platform. This IoT platform has been designed in such a way where anyone can connect any type of electrical/electronic device. It can execute user command using it's REST API, manages devices where anyone can check the status of a load and can control remotely. This secured IoT platform can also send E-mail, SMS, and alarm. It can typically handle different tasks such as store data, visualize data and works as a middleware solution between hardware and application layers. The Altair SmartCore IoT platform does not apply any charge for connecting first two devices.

With the rapid growth of smart technologies and uses of electrical equipments (light, fan, etc.) and sensors (humidity, temperature, etc.), it has become very hard to control and get information from them manually. To getting control of that devices and measures the data from them, Arduino is an easy and cost effective choice. Arduino Ethernet Shield is an Arduino extension which is used to connect Arduino to the internet for sending and receiving data and works as a micro-web server. When a user sends data as a command through the internet, this micro-web server fetches the data from the internet and sends command to the Arduino.

This paper is based on the design and implementation of a flexible, secured, low-cost, advanced home control and monitoring system. This system includes services such as gas leakage, fire extinguishing and trespasser protection. If any unauthorized person tries to enter the home, the system sends an SMS to the authorized phone number. The system has sensors. When the gas sensor finds anomaly, the system starts alarm through buzzer and the kitchen exhaust fan turns on automatically. Again, when the fire sensor finds anomaly the system starts alarm through buzzer and an emergency pump turns on automatically. The system sends SMS to the user for both cases. The system consists of a Teleduino server [4], micro-web server and Altair SmartCore server [5] for

controlling and monitoring home appliances from anywhere and anytime. Each time with the change of state of any appliance, the information is stored instantly and the system notifies the user by E-mail. This stored data can be checked from anywhere by logging in Altair SmartCore web server. So, the proposed system allows authorized home owners to monitor and control the home appliances remotely using the 'Home Automation' android or web app through server real IP.

II. Related Work

Nowadays IoT makes technology more advanced. IoT is the network protocol integrated with physical devices, home appliances and other embedded devices which enables these things to connect and exchange data over a network without the presence of human being [6]. IoT has a novel impact on home automation system. Smart home is not a new term, it has been developed from over a decade. Home automation or smart home provides convenience, comfort, security and energy efficiency to its householders [7] [8]. Smart home consists of wireless technology such as Wi-Fi, RFID, Bluetooth and cellular networks. These have been utilized to various embedded systems which sense, control and exchange remote data.

The paper in [9] presents a smart home system where Bluetooth has been used as a medium of communication, without any internet connectivity. The physical devices such as sensors, actuators which can be accessed and controlled by smartphone using built in Bluetooth connectivity is implemented in [10][11].

To overcome the limitation of using Bluetooth signal (maximum range 100 m), researchers also introduced a popular technology called Wi-Fi based home control system [12] [13]. In Wi-Fi based home control system, a dedicated webserver and personal computer have been used, which is complex and not flexible.

GSM based cellular network has been applied in home appliances management system for longer range communication than Wi-Fi [14]. AT command is used to control and communicate with home appliances. The main drawback is that GSM has no suitable Graphical User Interface (GUI).

The authors in [15] have used MIT App Inventor, NearBus, and Arduino to develop a smart home prototype for controlling the home appliances without any monitoring capability.

Moreover, in papers [21][22][23], authors have designed Raspberry Pi based home automation system which is very costly. They have not used any IoT platform so their system is not capable of checking current status of home appliances. No security system is proposed there as well.

In paper [24], the authors proposed IoT based smart security and home automation system. They used PIR motion sensor-based security system and phone's digit pressing user interface for controlling home appliances using TI-CC3200 Launchpad board. Considering all these issues, an IoT based home automation system has been designed and implemented that can be controlled remotely from anywhere.

III. Description of The System

A. System Architecture

This section describes the details architecture of the proposed system. The system architecture is divided into five layers; remote login, server connectivity, real time database with notification system, home gateway and home environment.

Remote login allows the authorized user to login and access the system with 'Home Automation' app from anywhere in the world using Wi-Fi or 3G/4G network.

Server connectivity is controlled by Teleduino server, which links up between IoT platform and embedded micro-web server using a unique key. Teleduino converts Ethernet enabled Arduino into a versatile tool for interacting with devices over the internet. Ethernet enabled Arduino automatically connects itself to the Teleduino server when it is powered on.

Altair SmartCore web server stores data and works as real time database management system. When any appliances present state is changed, the server stores it and notifies the user by sending E-mail using Altair SmartCore Email API [3]. It also sends SMS for specific appliances (door, gas & fire sensor) it will send SMS using Altair SmartCore SMS API [3]. To get this facility, the user has to first create an account to the IoT platform.

Home gateway is an embedded micro-web server based on Arduino Ethernet Shield. The embedded micro-web server maintains and controls the home appliances using HTTP request by navigating Ethernet Shield's IP address through browser.

Home environment is directly related with home appliances. It consists of electrical equipments, modules and actuators. Module such as RFID [16] has been used for smart door lock system that ensures the entrance of authorized user only. This proposed system includes sensors such as temperature, and humidity for monitoring the home environment.

B. System Implementation

This section presents the explanation of working principle of the proposed system. The home gateway system is divided into two-parts; server connectivity and TCP/IP protocol. The server connectivity has three sections; Teleduino server, micro-web server, and Altair SmartCore server.

To implement the system, at first it is needed to establish a connection with Teleduino server, which creates a link between micro-web server and Altair SmartCore server. The user first sends initial standard HTTP command (using 'Home Automation' app) to embedded micro-web server through the Teleduino server. The micro-web server passes the command to the Arduino and the Altair SmartCore server.

The home gateway is connected to internet over TCP/IP. Arduino Ethernet Shield also supports TCP/IP stack. During the configuration with TCP/IP, the Ethernet Shield establishes connection with Local Area Network (LAN) using public IP address. Thus it creates an embedded system using TCP/IP protocol [17]. Once the home gateway is initialized, Arduino gets ready to execute any command. Then it enters into idle state until any further command is received from the remote

user. When the user sends HTTP command successfully from the 'Home Automation' app, Arduino Ethernet Shield decodes the command and Arduino takes appropriate action accordingly. At the same time the decoded command is stored in the Alter SmartCore server and notifies the user through E-mail. The complete process is illustrated as a flowchart in Fig. 1.

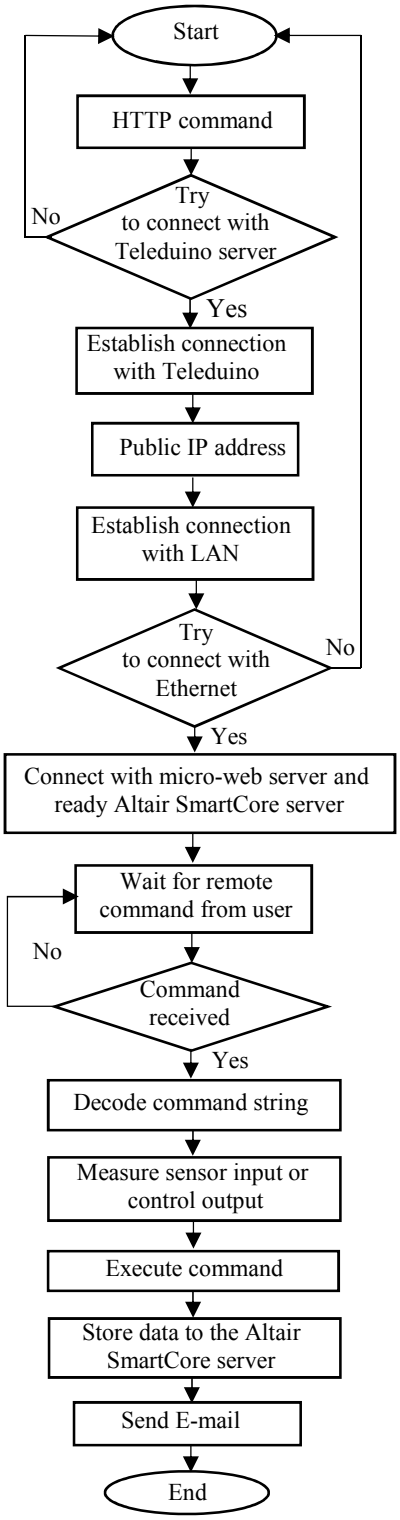

Fig. 1. Flow chart of E-mail notification process.

The home automation system includes some sensors and modules. The gas sensor detects gas leakage, fire sensor detects fire and keypad module is used for pressing password. The Arduino microcontroller is used to collect and analyze sensors data and controls the decision making process. The Altair SmartCore server stores the data and sends SMS. The complete process is shown in the following flowchart in Fig. 2.

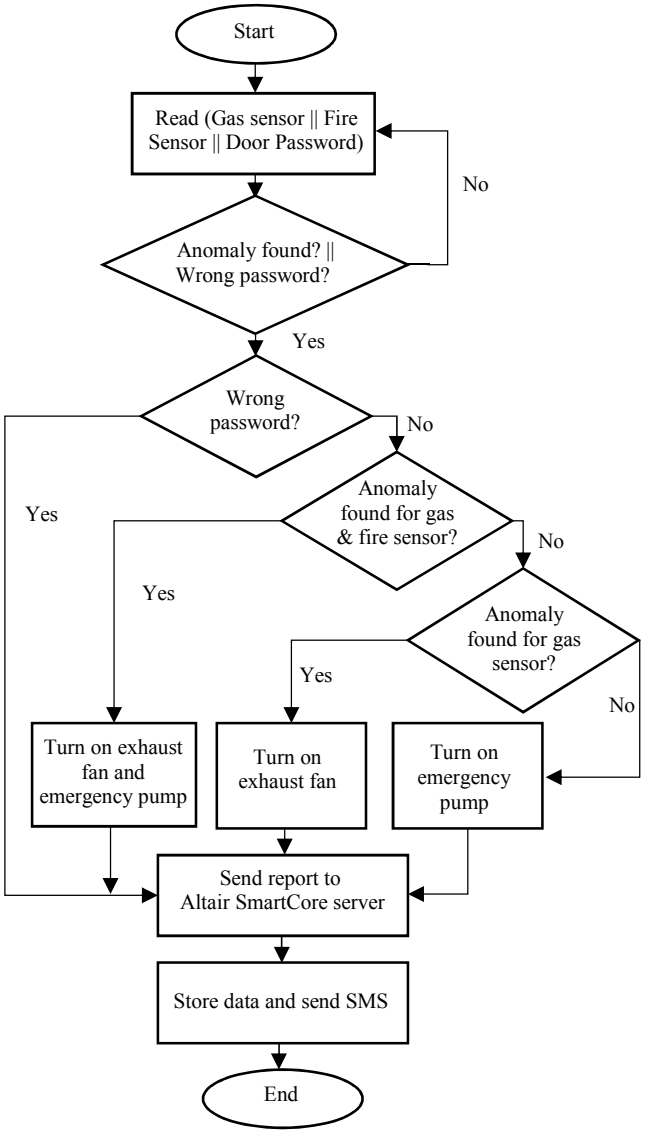

Fig. 2. Flow chart of SMS notification process.

C. *SystemFramework*

The home gateway framework is closely related with web services. The access and manipulation of web services have to be easy, direct, simple and interoperable. This eases the communication between the client and server applications of remote services. Web services are XML-based or JSON-based information exchange systems that use the internet for direct application-to-application interaction [18]. These systems can include programs, objects, messages, or documents. There are two main classes of web services; Simple Object Access Protocol (SOAP) and Representational State Transfer (REST). RESTful web service has a great deal with flexibility. It is much more stateless and lightweight than SOAP that offers functionality similar to SOAP based web services [19].

Therefore, this proposed system has used RESTful based web services. This service utilizes two standard operations: POST and GET. These two operations request and return

JSON response to communicate between the remote user and the micro-web server. JSON is much more lightweight for storing and exchanging data over client-server. It is easy for human beings to parse and generate messages simpler and faster than XML. For example, to turn a light on, an HTTP POST sends a request to micro-web server via Teleduino Server. After a successful operation the system sends response with success status response code "status": 200. The complete operation is illustrated as a data flow diagram in Fig. 3.

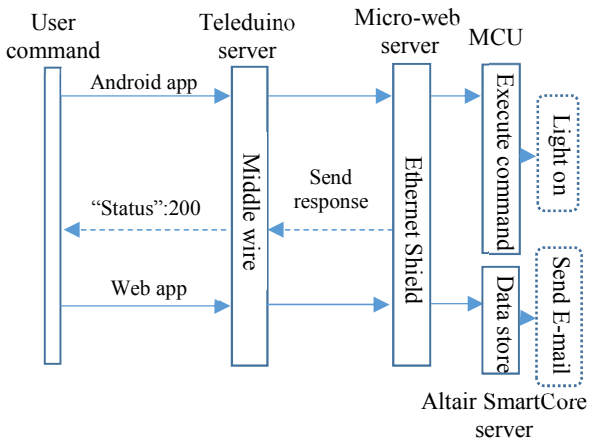

Fig. 3. Data flow diagram of web services.

D. Smartphone and Web Application

There are several platforms for developing smartphone application such as Android, Windows Mobile, iOS and others. About eighty eight percent people of the world use Android operating system as Android GUI is much simple and sophisticated [20]. Web application has been used productively because of the increased availability of information. These increases have led to heavier reliance on web-based application. Also, a web application can access anytime, anywhere through any web browser in any operating system with an internet connection. That is why this proposed system introduces both web application and smartphone application to control the home appliances. Fig. 4 and Fig. 5 illustrate the GUI of 'Home Automation' Android app and web application.

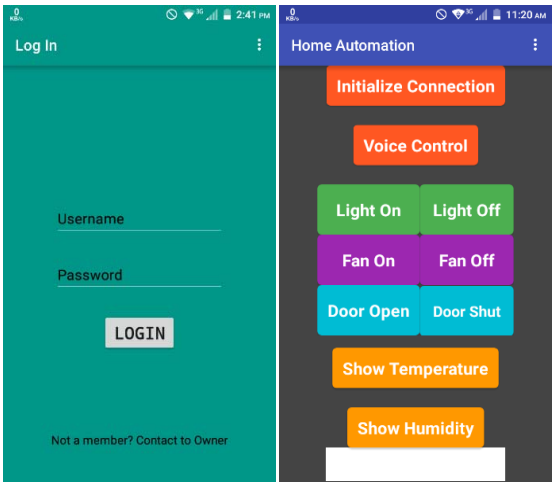

Fig. 4. Snapshot of 'Home automation' Android app with voice control option.

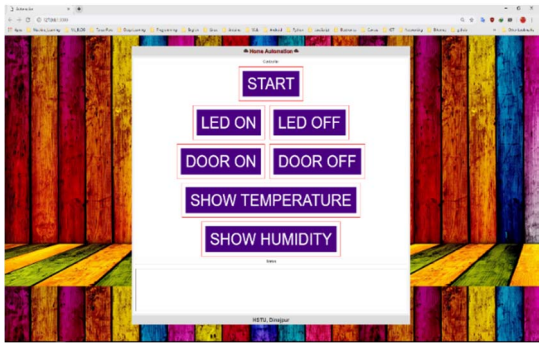

Fig. 5. Snapshot of 'Home automation' Web app.

To successfully control home appliances with home gateway, a user has to first connect with Teleduino server. When a user sends any command via 'Home Automation' app the micro-web server fetches it and forwards the request to the Teleduino server. The Teleduino server responses according to the command and sends back as JSON format to the user.

IV. Experimental Setup And Hardwire Configuration

The home automation system has used Arduino Mega as microcontroller board which works as the central control unit. Various modules including gas sensor, temperature and humidity sensor, RFID module, keypad, LCD, Relays and light/fan are interfaced to the Arduino board for testing the project. The experimental configuration and implementation of speech or manual control based home automation system are shown in Fig. 6 and Fig. 7.

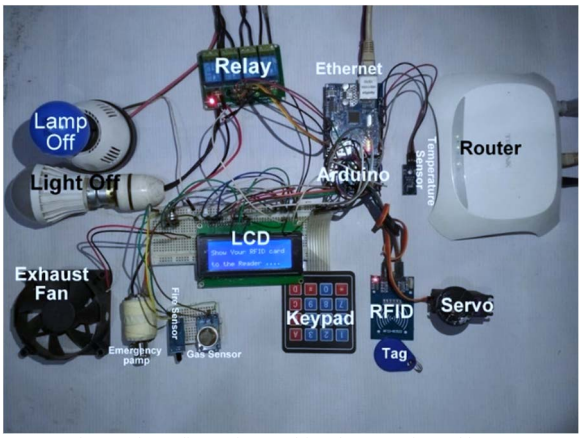

Fig. 6. Experimental configuration and implementation of home automation system with light and lamp off.

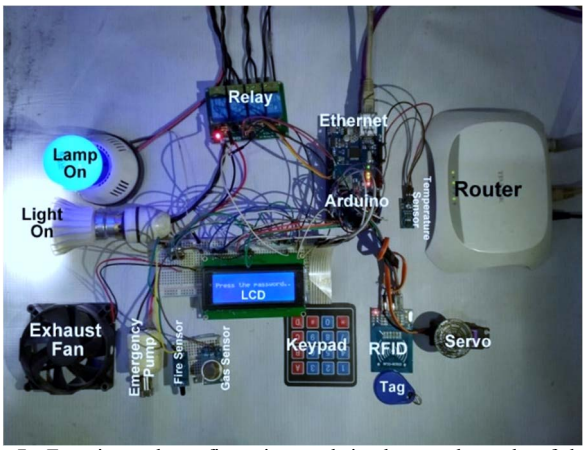

Fig. 7. Experimental configuration and implemented result of home automation system with light and lamp on.

This microcontroller board is interfaced with Arduino Ethernet Shield based on Wiznet W5100 Ethernet chip. The Arduino mega and Ethernet Shield are used to implement the micro-web server for home gateway control system. The Arduino mega 2560 is a microcontroller board based on the ATmega2560. A conventional light switch is integrated with Arduino using relays to demonstrate the switching capability. This system has sensors which detect input signals and actuators that perform responsive and adaptive functions. The experimental Setup of home automation system is shown as a block-diagram in Fig. 8.

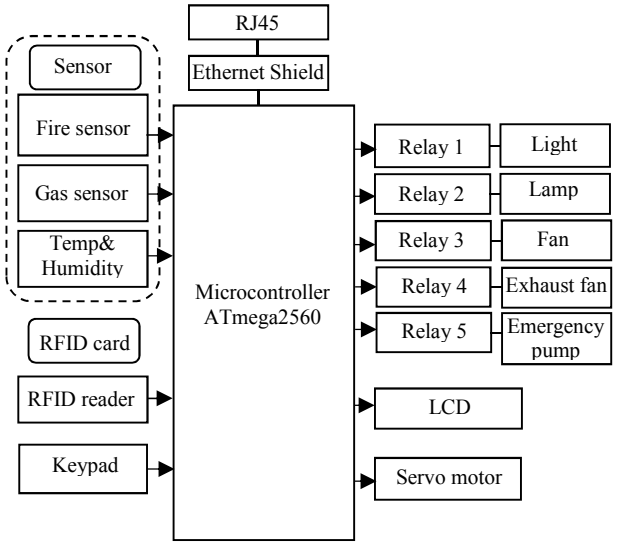

Fig. 8. Block-diagram of complete home automation System.

To configure this system, the user must connect with server through home gateway. To authenticate the user and to control the home appliances user has to first login and send initialize command through apps (smartphone/web) which will activate Ethernet Shield.

V. Comparison Study

A comparison study has been performed to measure the performance of the proposed system with other recent works. A table has been given below to compare the features of the existing works with the proposed system. The performance metrics cover many aspects such as real time database, instant notification through E-mail and SMS, control and monitor home appliances from anywhere and user interface. The TABLE I. shows that the proposed system is better than all others.

TABLE I. Comparison with Existing Works

Paper Ref. No	Performance Metrics				
	Real Time Database	*Instance Notification*	*Control home appliances from anywhere*	*Monitor home appliances from anywhere*	*User interface*
[21]	No	No	No	Yes	Web app
[22]	No	No	No	Yes	Web app
[23]	No	No	No	Yes	Web app
[24]	No	Yes	Yes	No	Digit of a phone
Proposed system	Yes	Yes	Yes	Yes	Android and Web app

VI. Conclusion

In this paper, an android and web based multi-functional advanced home automation system has been designed and implemented. The proposed system ensures easy and proper control of the home appliances from anywhere in the world. This system provides more security to a home by preventing intruders. It also protects a home from accident by removing leakage gas and fire extinguishing facility. This system is very beneficial for old ages, handicapped people and working people. The complete system has been tested and performed as expected. The GUI is user friendly and more practicable. The system ensures flexibility, reliability, energy efficiency, and a smart home.

VII. Scope for Future Work

In future, the home automation system would be made more functional. More home appliances will be included in the system. To improve the security of the system, facial recognition technique will be applied.

***Abstract*— Advancement in latest technologies has been helping to accomplish our day to day activities in faster and smoother ways. The advanced technologies provide solutions on multi-tasking with added security features in different sectors. Moreover, automation processes have been making regular life style smarter with less time-consuming activities. At the same time, the number of internet users has been increasing day by day. Internet of things (IoT) is one of the latest and emerging technologies that includes wireless monitoring & controlling functions with the help of internet. An IoT based Home Automation System (HAS) uses computers or webpage or android app for monitoring various parameters to control e.g., different electronic home appliances. By using the HAS technology, the users can access multiple appliances over the internet. By monitoring the parameters like temperature, light intensity, and movement of a human being e.g., using temperature sensors, the electrical appliances such as fan & light can be switched ON/OFF via internet from anywhere of the world. This paper proposed an IoT based home automation system which is designed with an aim of cost reduction and user friendly operation of the system.**

Keywords—IoT, HAS, MCU, sensor, notification, server, Wi-Fi, Blynk.

I. INTRODUCTION

Now-a-days, the technology has been advancing promptly, and with the development of this technology, the use of the internet is becoming enormous. The use of internet is further extended to connect things or devices to interact with each-other intellectually so that it can provide useful and meaningful information. This phenomenon is called Internet of Things (IoT). Undoubtedly, it is a must technology for the modern world. We can't imagine a single day without internet. With the development in science and technology, many systems have been developed for the betterment of human life. Home automation system (HAS) is one of them.

The HAS can control lighting, atmosphere, amusement systems, and appliances. Moreover, it can incorporate security of houses such as access control and alarm systems.. The HAS usually interfaces the devices to be controlled to a central hub or "gateway." The UI either uses divider mounted terminals, tablet or personal computers, a cell phone application or a web interface to control the system [1]. The HAS can be composed and created by utilizing a unit controller which can control and monitor interconnected appliances, e.g., lights, control plugs, temperature and moisture sensors, gas and fire locator, and security systems [11].

Various communication technologies can be used for the HAS, e.g., RFID, ZIGBEE, Bluetooth, GSM and Wi-Fi [2]. Every communication system has some drawbacks. Some systems use conventional technologies. Some systems use modern technologies which also have some limitations in monitoring and controlling the components that are related to the automation system. In the RFID based HAS, the energy meter is credited through the subscriber controls RFID technology and the automation of different appliances via an Android mobile application [7].

In RFID based internet of things system and service, it presents a novel readout strategy for a different leveled remote ace slave RFID reader engineering of multi-standard NFC (Near Field Communication) and UHF (Ultra High Frequency) advances to construct a smart home automation system [8]. In the Wi-Fi-based HAS, the concept of internetworking of smart devices is crystalized. According to [9], a Wi-Fi based Wireless Sensor Network (WSN) can be used to monitor and control e.g., electrical parameters of a smart interconnected home. Speech based HAS is presented in [10] where two schemes are implemented. First one is Bluetooth technology, and the other one is GSM/GPRS technology. ARM11 Raspberry Pi microcontroller board is used in that system.

In the ZigBee wireless interface management module a ZigBee device module is fundamentally in charge of the correspondence between the host PC and ZigBee remote system, ZigBee home system data criticism, and so on [6]. In such a system it is necessary to establish a network and a sub-network for further control. The Bluetooth based HAS incorporates a host and a few customer modules. Considering the passageway cost of the Bluetooth, it will be more financially savvy to have different devices Controllers associated with a Bluetooth device [3]. However, this system ranging problem and also has a limitation of the number of connectors to the Bluetooth device. In GSM technology,

when an SMS is sent to GSM module by Mobile, then GSM receives that SMS and forwards it to Arduino. Typically, Arduino reads this SMS and extracts basic command from the received string and stores it in a variable. Then, Arduino contrast this string with e.g., a predefined string. If matches happen then Arduino forwards the signal to relay via relay driver for switching ON and OFF the home appliances.

Moreover, relative outcome additionally prints on 16x2 LCD by utilizing suitable commands [4]. As the system is network dependent, it can easily get interrupted [5]. If a user makes any mistake in writing message format, the message would not be acknowledged by the Arduino device [5]. Hence, the HAS cannot be applied economically and efficiently in those systems. To overcome the limitations, this paper suggests a low cost, energy efficient system for the people.

Furthermore, the HAS can be accomplished by combining the GSM technology with short-range wireless communication technology, Bluetooth, and colse proximity ZigBee wireless technologies. The client **c**oupling has been accomplished using Android application. Th**e** Android application gets client's vocal information to portray an arrangement of printed directions. The portraid directions are transferred using SMS service to **a** telephone in house and exchanges the paths to a PIC controller using Bluetooth. This unit has been referred as a remote unit which then transfers the directions to a dedicated ZigBee handset which then exchanges these directions to the main controller using ZigBee technology**.** The controller then translates the instructions and plays out the planned activities. Moreover, it transmits back the status data using the ZigBee technology. Th**e** framework can provide remote access. Nonetheless, the frame may end up costly because of the utilization of various types of controllers. Additionally, the SMS framework can turn out to be not reliable [15].

In this proposed system, one will monitor various home appliances e.g., electrical appliances like light, fan, AC, etc., the condition of gas in our kitchen, the room temperature, and the presence or absence of residents in a house. For this automation purpose, the IoT technology is more reliable, cost-effective and provides more information. IoT is one of the promising advancements which can be utilized for associating, controlling and monitoring wise articles which are associated with the internet through an IP address [12]. The system can be controlled via voice recognition system. The voice command given by the owner is translated by the cell-phone utilizing Natural Language. The cell-phone goes about as a focal comfort; it figures out what task must be finished by which apparatus to satisfy the client's demand. The focal reassure may in like manner be either a work area application, web application or an advanced mobile phone application as almost the majority of the information exchanged can be handled by the cloud [13].

This paper aims to control the household electrical equipment through the use of the internet. A normal HAS comprises of 4 phases. Understanding the client condition by detecting, revealing the occasions to a brought together substance, concentrated element investigations and triggering the work process, work process will be executed and refresh client by any intelligent channels or even exercise over a home gadget (inciting) [14]. This system will be conducive for the person who leaves their house without monitoring the condition of electrical appliances. A person can control the state of electrical devices of his/her residence from anywhere of the world. If the dwellers go out, it becomes a great concern for the dwellers of the house. So it is essential for the dwellers to monitor the house. The proposed system in this paper can help in this regard by providing home automation such as controlling the current states of various electrical appliance, gas, and temperature using IoT technology. Anybody with the knowledge of the address of the web server can monitor the condition of home appliances and parameters in real-time.

Fig.1 shows the block diagram of the proposed home automation system. Every systems and sub-system will be depicted from where its operating procedure can be described. Various sensor modules will be connected with a microcontroller. The sensors will provide their outputs to the microcontroller. Then the microcontroller with having an adequate power supply and necessary processing and calibration shows this value via a mobile application. Again, the microcontroller connects to the internet using wifi module and sends the values to a remote IoT server where the dwellers or connected person can view the state from anywhere of the world.

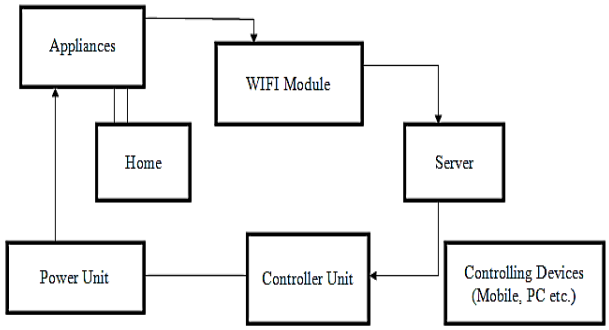

Fig. 1. Block diagram of the IoT based HAS

II. SYSTEM HARDWARE

The primary objective of this automation system is to design a HAS that is cost effective with higher reliability and which can be controlled from a long distance.. A smart control system can be developed with the use of IoT. The entire system consists of a microcontroller unit with Wi-Fi accessibility, a control unit, and a power unit. Fig. 2 shows a basic diagram for the whole of the home automation system. In the system, the heart of the system is Node MCU ESP8266, which is a microcontroller with Wi-Fi accessibility. This Node MCU ESP8266 is connected with the sensors and electrical appliances.

For controlling and monitoring the home electrical appliances, the user has to browse the particular web server; thus the user can control the status of the electrical appliances and in case of gas leakage, and if any motion detected by the sensor, it will give notification via a mobile application. So that the user need not browse the server all the times to know about sensors output. Different sectors of this HAs are:

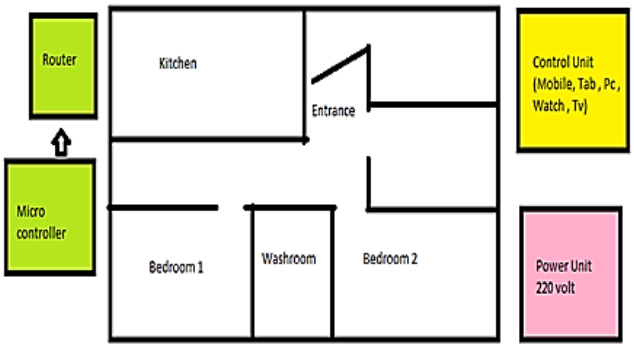

Fig. 2. Design of Home Unit

A. *Controlling Light, Fan or AC*

The States of various electrical appliances such as light, fan or AC can be monitored as well as controlled manually by a switch and automatically by the server.

B. *Open or Close a Door*

The door can also be controlled in this HAS. The door is connected with the Arduino microcontroller by a servo motor.

C. *Motion Sensing*

If the PIR motion sensor detects any motion, the sensor gives high output. Thus the microcontroller unit provides output to the controller unit as "Motion Detected." Fig. 3 shows the experimental setup of the proposed HAS. This HAS system consists of described appliances and sensors.

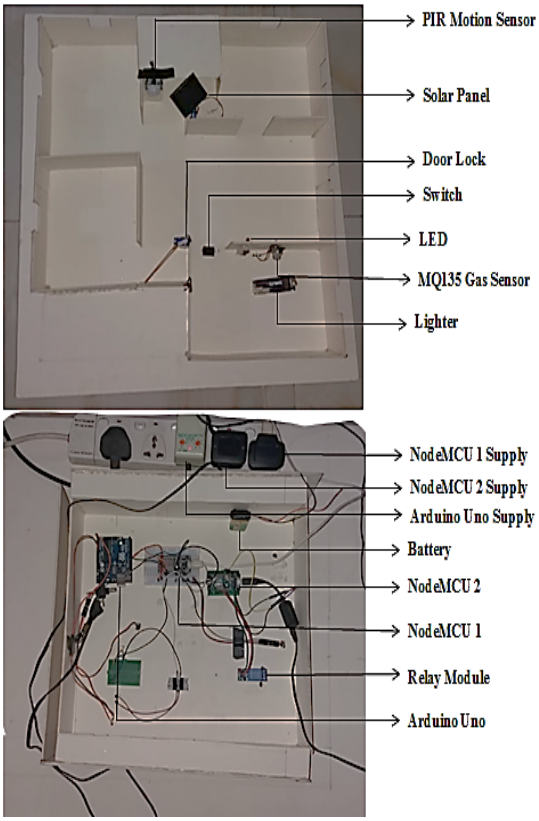

Fig. 3. Experimental setup for IoT Based Home Automation System

D. *Controlling Rotating Solar Panel*

Sun is a non-conventional source of energy. For which solar panel is placed up in the roof-top of the house. So according to the position of the sun, if the solar panel is placed, it can gather more power from the sun. By using a servo motor such placement is possible. By setting a definite angle according to the sun, the rotation can be made. By the use of the server, this rotation can be made from anywhere.

E. *Gas Leakage Warning*

In case of any inflammable gas leakage the MQ135 gas sensor senses the gas; thus there occurs a significant change in the conductivity of the sensor. So the sensor gives the output to the microcontroller unit, and from that, a notification arrived in our control unit such as mobile, tablet, PC, etc.

III. Hardware Programming and Application Development

A smart central controller Node MCU ESP 8266 is the fundamental component of the WSAN that is responsible to sort out and set up the remote monitoring system with control modules. A relating control module controls every machine. The home controlling unit is the main unit by which we can control the appliances of the system. The controlling devices can be mobile, tablet, laptop, pc or any other electric devices which has internet accessibility. Fig. 4 shows the flowchart of the proposed HAS. The smart central controller Node MCU ESP 8266 is a connection between the preceding and the following such that it merges the aggregated framework together. It is at the helm of laying out an RF 433 MHz WSAN e.g., in a home. These adaptable control modules are at the helm of commanding machines as well asspeaking with the principal supervisor. By using such a control framework, the occupants can employ mobile phone and/or PC to visually display home appliances and peform planned activities remotely, for example, turning on or turning off a lighting loads.

The software of the proposed HAS is isolated to server application programming and Microcontroller (NODEMCU) firmware. The server application proposed for the investigated HAS is used as online application constructed by using PHP, JAVASCRIPT, CSS and HTML. Server application programming is dependable of setup, arrangement and keeps up the entire home automation system. The server utilizes the database to keep a log of HAS parts, and we utilize JSON design spare system log. The Arduino programming, constructed employing C dialect, and also using IDE (Integrated Development Environment) coexist with the microcontroller. Arduino programming used in charge of gathering events from related sensors.

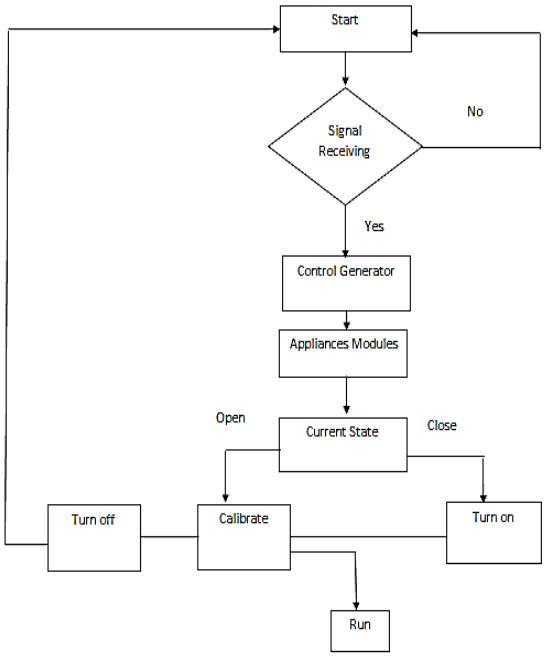

Fig. 4. Flow Chart of the Total System

IV. GRAPHIC USER INTERFACE

The essential requirement of HAS is to monitor and control the states of the electrical appliances using any mobile, PC, tablet, laptop, etc which are connected with the internet through the server. The electrical appliances and the solar panel controlled through the server. To make the system more effective, the sensor's output will be given via mobile application named as Blynk. Blynk software designed for such application to provide notification when the server gets the high output from the sensors.

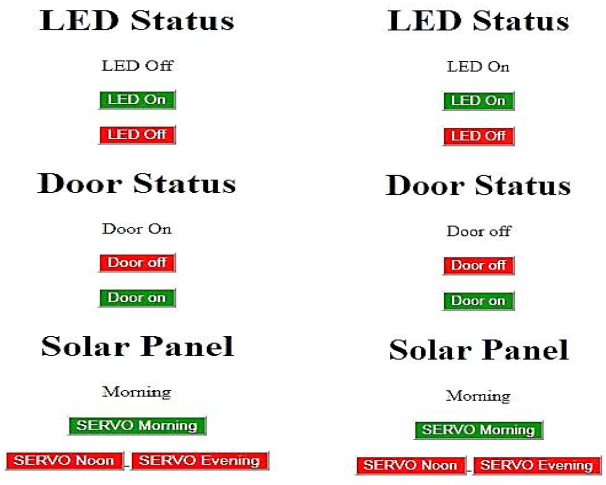

Fig. 5. Server Shows Different Appliances Status

Fig. 4 shows the server presents the status of LED, door and solar panel. When LED is off by tapping 'LED On' on the server the LED becomes on the state.

The door is automatically controlled via the server. While door remains off in state, by tapping 'Door On' on server the door opens.

The server shows the solar panel contains three states morning, noon and evening. According to the direction of the sun, the user can rotate the solar panel for capturing maximum power.

Whenever any flammable gas leakage occurs, gas sensor MQ135 becomes active, and it will notify via a Blynk application, Fig. 5 shows the result shows in the application.

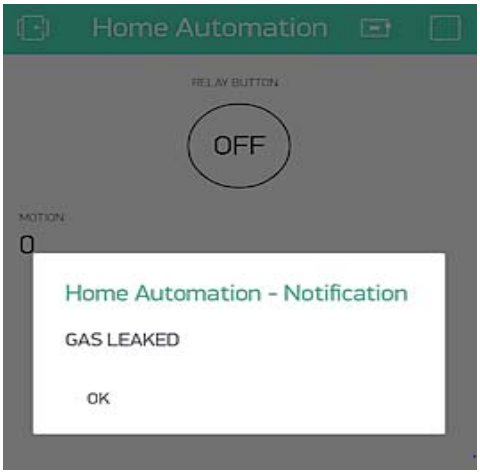

Fig. 6. Gas leaked Notification on Blynk Application

If the PIR motion sensor detects any motion, the sensor will also give notification via the Blynk application. Fig. 6 shows the notification of the application.

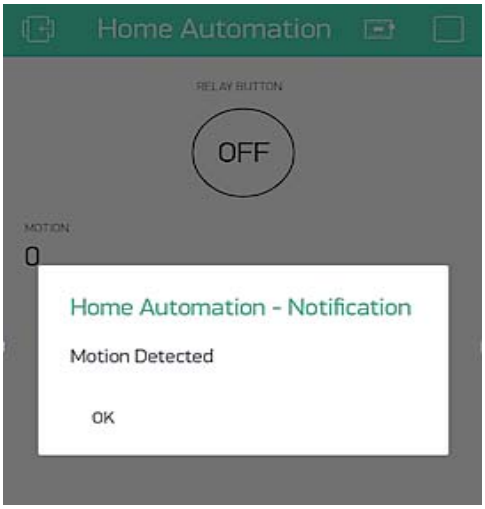

Fig. 7. Motion Detected notification on Blynk Application

By the use of server and the Blynk application, the HAS becomes more cost-effective, and it becomes easier to monitor and control the appliances.

V. CONCLUSION

In this work, the primary objective was to develop a HAS which can provide a more cost-effective solution with wide range of application. With the proposed HAS, more flexibility can be achieved as it uses the server to monitor and control appliances via internet access. The system can be installed into a house with an overall cost less than 100 USD. This system can also be useful for the handicap people to monitor the appliances. Various sensors can be used to perform applications such as water level indicating, rain alarm system, etc. This system can also be used for the industrial purpose so that the total industrial system can be controlled from a remote place by creating a domain based website. For the future improvement of the proposed HAS,

an automatic phone call system can be added. In case of gas leakage and fire alarm, the respective authority would get phone call automatically which would make the whole system more reliable when the dwellers are not in the town.

Abstract— **Developing human's life activity with enhancing safety and security protocol Android-based automation is a vast alternative. This paper presents the design and implementation of an Android APP based home automation system which achieves multiple objectives about Password-based access control, induction motor speed and light intensity control, any electrical appliance switching ON/OFF and all unnecessary electrical appliances turn off automatically by counting person if no person is present. The work is constituted with a microcontroller, IR sensors, and HC05 Bluetooth module for confirming the wireless environment using Bluetooth technology and a software interconnection is also shown for proper using. Finally, this project eliminates the traditional method of controlling AC appliance and the process of individual involvement which makes life easier and faster in daily households need for everyone.**

Keywords— **ATmega8, Microcontroller, Android APP, IR sensor, Zero crossing detector, Relay, TRIAC Opto-coupler, Bluetooth module, LCD Display, Lamp**

I. INTRODUCTION

With the development of technology, the behavior of human's life is changing very fast. Nowadays Android phone is one of the most commonly used devices around the world. its demand is increasing with time and because of its' multi-dimensional functionalities and most enhanced applications. Today home automation is one of the most important application of Bluetooth technology. There are some objectives involved when designing a home automation system. Our project provides high security, electrical safety, power savings and reliability.

A speech recognition system where speech detection device is a mobile device's microphone [1]. This system can only turn on/off the home appliances, not voltage control. Besides vocabularies, multiple users and noisy environments are the major factors that affect the performance of the system. M.Preethi and R.Dharmalingam implemented a fan controlling system using an Android APP through wireless Bluetooth [2]. It only performs single work and operates DC fan but our system comprises multiple approaches. M. N. Azni et al. proposed Android Application based home automation [3] which controls different home appliances through wireless using Raspberry Pi but this project is costly. Our project proposes a low-cost solution. Shah Modi designed an RF-based home automation system which can do on-off of 15 devices using a single remote [4]. This system only controls the speed of a DC motor but not an AC Motor. Neng has proposed, and architecture for home automation [5] where the system was based on a dedicated network. This system only helps how to compose home automation problems at the software stage and no hardware stages were considered. Yavuz and Hasan [6] introduced a telephone and PIC Microcontroller based remote control system. Here the operation is performed using a dedicated telephone line not via Bluetooth technology. Ahammed presented DTMF (Dual Tone Multi Frequency) based Home appliances control [7]. DTMF based system can control electrical appliances from long distance but two mobile handsets (one for calling and one for receiving the call) are required and there will be call charges imposed from the service provider to the individual for each call. Sriskanthan introduced a Bluetooth technology based home automation system that can control home appliances from a PC using [8]. However, the system cannot be interfaced with the cell phone. A cell phone based home automation through Bluetooth communication which allows the user to monitor and control (only ON/OFF control) but not controlling AC voltage, has been discussed in [9]. In [10] S. Dey et al. and in [11] K. Mandula et al. proposed internet of thing (IOT) based home automation that can operate electrical appliances remote place through internet but its response is very slow and always must have an internet connection.

Considering these matters, we designed a system that can mitigate the above drawbacks at the same time it has been characterized with Multi-function.

II. HARDWARE ARCHITECTURE AND IMPLEMENTATION

The system hardware consists of three main parts such as (a) Password based access control. (b) AC voltage controlling and any electrical appliances switching (ON/OFF control) using Bluetooth communication of android (c) IR based person counter circuit.

A. Password based access control using Android APPS

This part adopts an HC05 Bluetooth module, MC, L293D motor driver & DC motor and other indicators electronic component. Here HC05 Bluetooth module that is interfaced

to Microcontroller is used to receive the data sent from APP. Any data is sent from the Android APP for different objectives to the Microcontroller through USART using Bluetooth communication. When a user sends a correct password, the green LED turns ON and the MC allows the user to enter into a secured area, whereas on sending a wrong password, the red LED & buzzer turns ON and the user will not be allowed in the secured area. The instructions of every step will show on the LCD display so that a user can easily understand the whole system. The Block diagram of this part is given below:

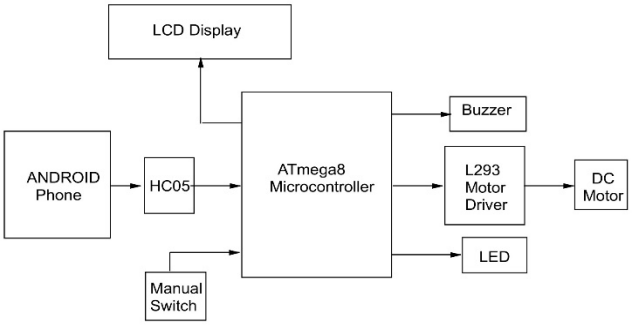

Fig.1. Block diagram of Android based access control system

B. *Android based AC voltage and electrical appliances control*

This part adopts a Zero crossing detector, MCU, Power circuit and other appliances controlling circuitry. The circuit diagram of AC voltage controlling is shown in fig.2.

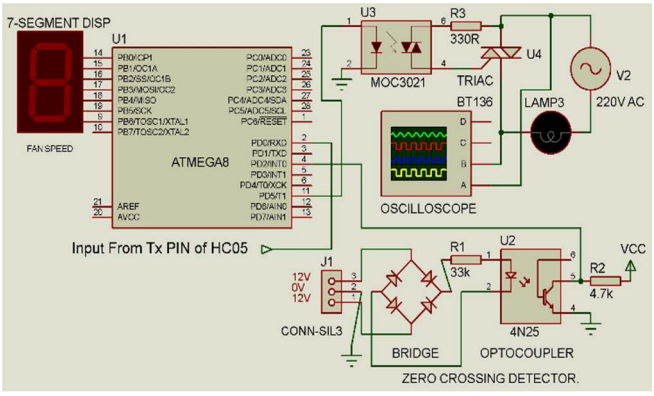

Fig.2. Circuit diagram of AC voltage control mechanism

Zero crossing detector which is made using an MCT2E optocoupler, bridge rectifier, and two resistors, produces very short duration positive pulses at each zero position of the sine wave input AC signal. These pulses are fed to the INT0 pin of MC through the optocoupler. The interrupt is produced at each zero position by the short duration. After that, the microcontroller generates control firing pulses per interrupt based on the receiving slider value of android app using a specified pin of output port which triggers the TRIAC as per requirement. TRIAC is a power electronic device that provides controlled output load power when triggered through the gate by using a phase angle control technique. The RMS value of AC voltage is controlled by the variation of firing angle (phase delay) of the TRIAC. Here MOC3021 is used for the isolation purpose between power circuit and control circuitry. The controlled output voltage is displayed in seven segment display from 0 to 9 corresponding the varied output ac voltage. Any electrical appliances on /off control mechanism is shown in fig.3.

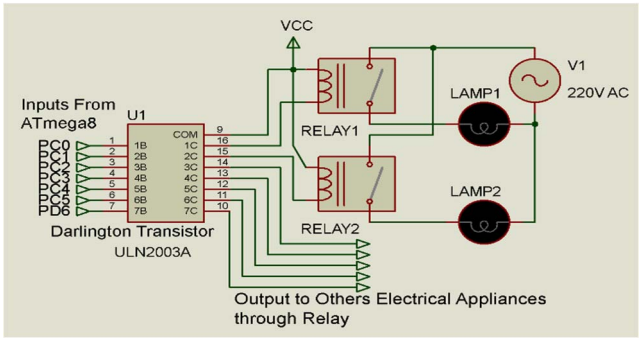

Fig.3. A connection of electrical appliances with ULN2003A via Relays

Here ULN2003A Darlington transistor which is connected directly with digital output pin (PORTC & PORTD) is used to operate the relays for providing required current.

C. *IR based person counter*

The arrangement of person counting is shown in fig.4 where two IR sensors are used to detect the presence of a human. The whole counting mechanism is performed by a microcontroller.

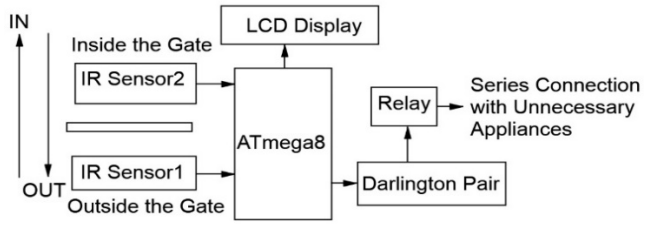

Fig.4. Block diagram of person counting mechanism

When a person enters the room, the counter value is increased, whereas on leaving, the counter value is decreased. If the counter value is zero (i.e. no person presents in the room) all unnecessary electrical appliances turn off automatically. If the counter value is greater than zero, the system will run in normal operation.

III. SOFTWARE DESCRIPTION OF THE SYSTEM

Here we have designed an android APP using online based open source android app inventor platform which is provided by Google, and now maintained by the Massachusetts Institute of Technology (MITC). App interface of Password based access control is shown in fig.5 and App interface of AC voltage and electrical appliances control is shown fig.6.

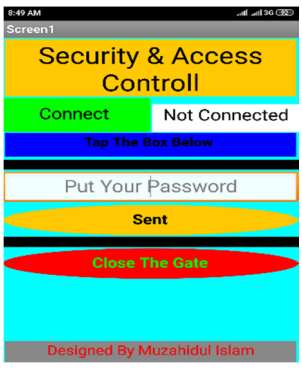

Fig.5. Screenshot of Password System APP interface

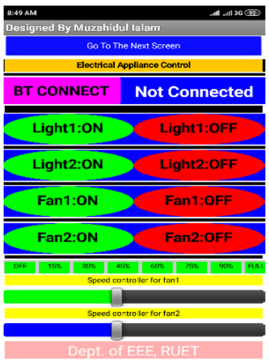

Fig.6. Voltage & Appliance control APP interface

when any push button on APP interface is pressed a specific ASCII value is transmitted to the MC through Bluetooth for the desired operation.

For Microcontroller programming, C language has been used for software design of the system. This program is written in Programmer's Notepad. The program has been written for three distinct output: Password system, Appliances control and Person counting. Fig.7 shows the basic flow chart of a Password system.

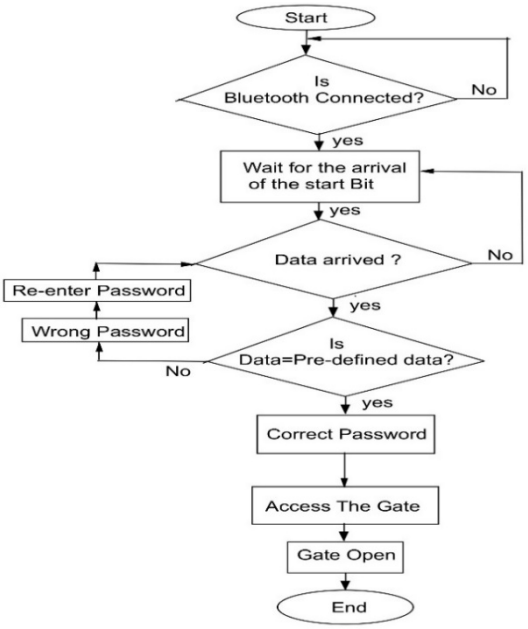

Fig.7. Flowchart of password based security

A password has been set in the MCU by software, which is 9 characters in length. When a user sends a password from the android app through Bluetooth to the MC, if this password matches the pre-defined password, Access will be granted otherwise denied. AC voltage controlling action in a flowchart is shown in fig.8

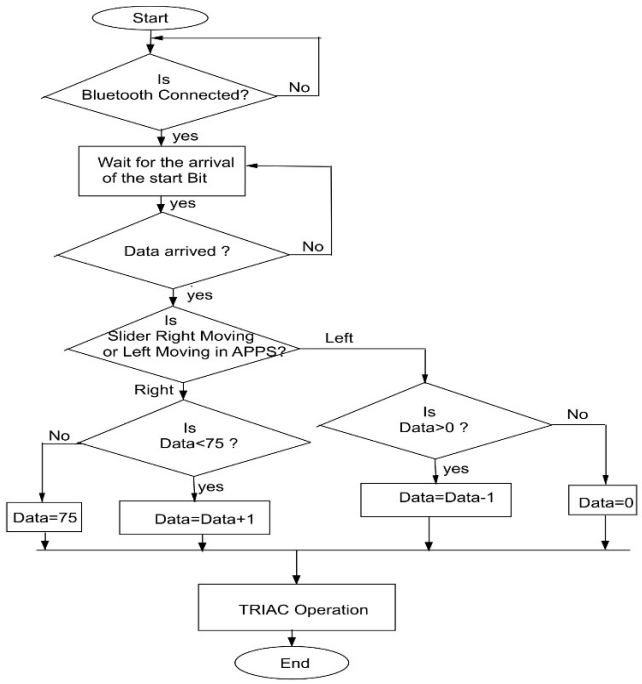

Fig.8. Flowchart of voltage controlling action

For controlling of AC voltage (i.e. a variation of RMS value of AC voltage), the Slider Thumb-position on Android APP interface is moved left or right. As a results, a changing ASCII value from 0 to 75 which is sent to the MC through Bluetooth communication is accumulated UDR buffer register. The UDR value is put in OCR2 through a globally defined variable for calling TIMER2 interrupt in every maximum value of OCR2, and MC provides control firing pulses that trigger the TRIAC via port pin. Then TRIAC provides a controlled output RMS voltage as per requirement.

For switching an electrical appliance, a specific character is sent by pressing a push button on the Android APP then the corresponding appliance is switched (ON/OFF).
For counting person, if the IR sensor1 detects the human first next IR sensor2, the counter value is added by 1. But if the IR sensor2 detects the human first next IR sensor1, the counter value is subtracted by 1. The counter value shows in the LCD display. If the counter value is greater than zero, one output pin of MC that goes to high turns on a defined relay. As a result, all unnecessary appliances is operated in normal mode. If the counter value is equal to zero, the same output pin goes to low, which turns off the all unnecessary appliances

IV. RESULTS AND DISCUSSION

Fig.9 shows the simulation result of the voltage controlling action in Proteus oscilloscope window. The controlled output curve shows the 10% voltage of input voltage. For the 10% output voltage, the firing pulses trigger the TRIAC at 9 MS delay from zero crossing of the input sine wave. Similarly, for 60% and 90% output voltages, the firing pulses trigger the TRIAC at 4 MS and 9 MS delay from zero crossing of input sine wave respectively. Fig.10 and fig.11 show the output curves of 60% and 90% voltage of input voltage respectively.

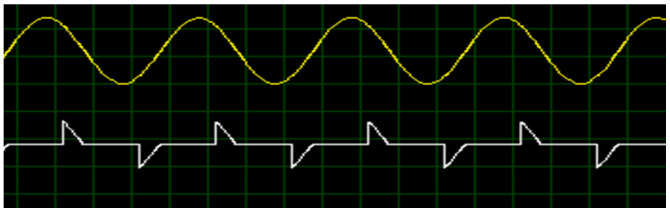

Fig.9. Input and 10% output voltage wave shape

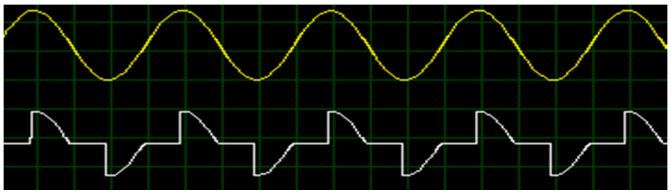

Fig.10. Input and 60% output voltage wave shape

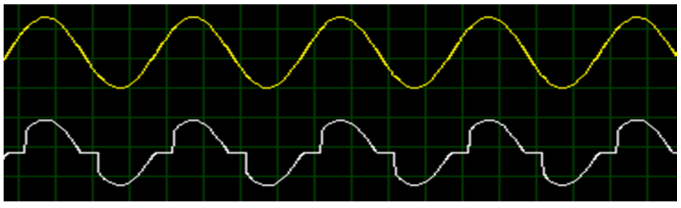

Fig.11. Input and 90% output voltage wave shape

The practical results of the whole project are shown in fig.12 and fig.13. Here two display has been used for password interfacing and person counting. Two light has been used to turn on/off and the other two light change the intensity which represents the controlling of the AC voltage. In the left side of fig.12, a DC motor attached model of a door is included. When the user password matched with the predefined password, the door opened and automatically closed after a predefined time. When the user password did not match with the predefined password, the system did not allow the user. When only the counter value was zero (no person present in the room), all unnecessary electrical appliances automatically turned off. Otherwise, the system is running in normal mode.

Fig.12. Complete setup with Test result

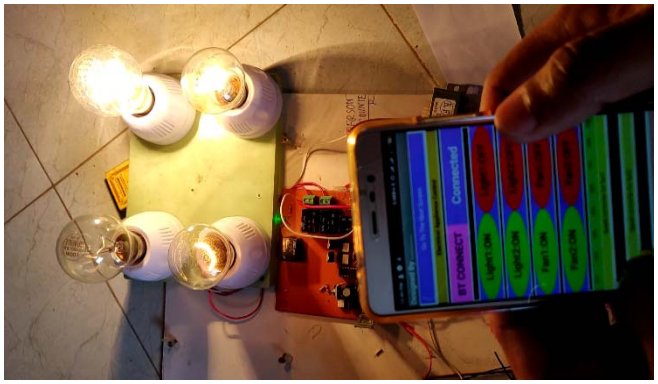

Fig.13. practical result of AC voltage controlling using Android APP

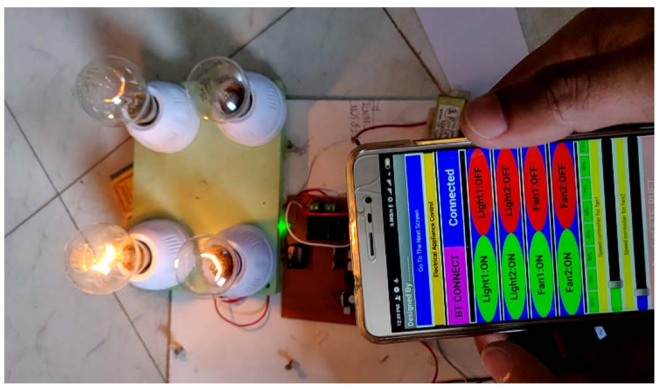

Fig.14. Switching ON/OFF and AC voltage controlling using Android APP

In fig.13 the lamp intensity which represents the controlling of the AC voltage is being controlled. When the slider position on APP interface is moved right or left, the controlled output voltage changed the intensity of light smoothly. In fig.14 one lamp turned OFF by pressing OFF marked push button and the intensity of other lamp decreased by moving the slider position to the left side.

V. CONCLUESION

In this paper, we have described a design and implementation of stable, flexible, safe and non-contact solution to the home automation. This system uses an Android APP to control the AC voltage (speed of induction motor) and the electric relay as well as it operates the password based access control through Bluetooth communication. The complete setup is successfully exposed to home appliances by controlling the intensity of light and switching on/off. This APP can control multiple numbers of appliances and the number of controlling appliances can be increased without any external circuitry. It provides high security and modernization of home automation. This system can reduce electrical hazard and misuse of electrical power. The work presented in this paper can further be extended for commercial, industrial applications and educational institutions.

***Abstract*—In this paper, a smart home automation system is proposed to control home appliances and to make a home safer using electronic controller. Also, Grid-Eye sensors are used to detect the presence of the occupant in the home upon which the activation of any appliance depends. As a result, all the electric instruments of the home run automatically when necessary, and the residents do not need to turn on/off of any electric appliances like air conditioner, fan, light, water heater or any other home appliances. Also if a person wants to make on/off of any utilities, he can easily make it by using android apps or by using a wireless network which is interfaced with the system. In addition to home automation, when any mishap happens in the home, GSM sends SMS to warn people about the accident. If a person wants to know the status of his home utility system, when he or she out of the home, he can also use GSM technology. Proteus simulation software is used to test the effectiveness of the proposed designed system. To control large electric machines like water pump, elevator and generator, PLC module is used. In this case, we also consider different conditions to run large electric machinery automatically. This designed system provides more convenient and flexible control for a smart home or a building. If implemented, the model will be beneficial for the promotion and popularity of smart home automation system.**

Keywords— Grid-Eye sensor, microcontroller, GSM module, Arduino IDE software, Proteus simulation software, PLC.

I. INTRODUCTION

Smart home system and home safety are vital issues for our modern life. Electronic advancement moves us to this development. But in most of the smart home system, the presence of people is ignored or the residents need to turn on/off electric appliances used in their home. The smart home system is an automated home with control devices associated with lighting, heating, air conditioning, ventilation, and security system [1]. Sensor and microcontroller are the main parts of the smart home system. In this case, sensors collect data from the surroundings and send electric signals to the microcontroller. The microcontroller processes this signal, and depending on the installed program in the microcontroller, necessary actions are taken to control the utilities connected to it. So, we can say that microcontrollers are the central axis of this system, and are sometimes called "gateways". The microcontrollers are usually interfaced with a tablet, mobile phone, or computer; and the network connectivity of the systems is managed by IoT [2]. Using this system, the controlling of all the electric appliances is possible which makes a home automation system. Android apps are also used to build home automation since Wi-Fi or Zigbee is available nowadays.

When designing a smart home system, the system should be flexible, affordable and scalable for integrating new devices into the system [3]. Moreover, the smart home system should be tiredness and boredom reducer to us. An important concern of the smart home system is the reduction of energy consumption and saving money for poor people [4].

There are many smart home research works in the online. In this paper, sensors and microcontroller are considered to control light, air conditioner or other home appliances only when they need to operate. In other words, when people are not present in the home, the light or air conditioner do not need to operate whatever the condition of the surrounding. For this reason, Grid-eye sensors with other sensors are used to detect the presence of the people. The surrounding conditions are only considered by the microcontroller during the presence of an occupant. When the output of danger warning sensors used, in the system, upon a critical level, the microcontroller does not consider the output of Grid-eye sensor and sends a warning to the people. As a result, the home will also be saved. In this designed home automation system, power will be reduced at the lowest level since utilities only run when people present in the home.

In case of controlling water pump, generator and elevator of a building, we interface PLC with the system since it is more reliable in this case. Also, we consider different conditions like the water level in case of the water pump and the presence of people in case of elevator and generator to run these electric appliances.

II. LITERATURE REVIEW

A smart home is the network of physical devices that provide electronic sensors, software, and network connectivity with each other inside a home [1]. Sometimes we consider a significant feature of the smart home is remote controlling [5]. There are numerous research papers related to smart home or home automation. A query on Web of Science, Science Direct, and IEEE Explore found almost 1798 papers in 2017 related to smart home [1]. In 2006, Davidoff et al. [6] published a paper related to the smart home and emphasized on control by end-user programming. Since 2010, researchers have been analyzing smart home based on IoT applications using many approaches. Stankovic [7] discussed the notion of smart car, smart homes, smart phones, and smart devices. An imagination of future intelligent home has been presented in some papers [2][8] where Zigbee (Wi-Fi) technology was considered. For managing power consumption, Zigbee-based smart home system is designed and implemented [9]. The smart home system is also designed by using android apps where

wireless Bluetooth system was used to assist disabled and elderly people [10]. Analyzing an original architecture and integrating it in a system, a smart home system is designed where IoT used in a paper published in 2013 [11]. IoT based home automation is versatile and popular. Numerous IoT based home automation systems are designed using many sensors to control electric appliances and to decrease the energy consumption [12]. Home automation system was designed using Global System for Mobile Technology (GSM) by Teymourzadeh and Rozita [13] in 2013 and their designed system was tested on four loads and its accuracy was 98% [13]. Smart traffic light control system was also designed where the prototype was presented to control traffic congestion using PIR sensor to calculate the number of vehicle on the road even the number plate of a vehicle is captured in this system [14]. Using wireless sensors networks (WSNs) interfaced with IoT to build smart home system is also available nowadays [15][16]. To connect objects like mobile phones, internet televisions, and sensors to the internet where the devices build new forms of communication, IoT is widely used [17]. But the main problem of this system is the cost of the wireless sensors, and the Wi-Fi network needs to keep connected all the time for communication. C. Barz et al. [18] used TIA Portal V12 and Siemens PLC to design smart home automation system where lighting, heating, irrigation, security system were considered. Raspberry Pi-based home automation system is also available nowadays where Raspberry Pi is used as a communication gateway between different home appliances and mobile [19]. To restrict the home automation for certain people, the command of user upon which the activation of home automation depends is proposed in some papers. Many firms assert that a smart home automation system can save 30% energy usage without comprising any comfort of the residents [20]. Home automation system balances demand-supply of power inside a home. As a result, it will reduce energy consumption and increase efficiency [21]. Using robotic system in a large electric machine like generator will not only save energy consumption but also reduce carbon emission in the environment and will help us to reduce the major global concerns of climate change and energy security [22].

III. Methodology

In this paper, we consider a home automation system to overcome many practical difficulties. Among many difficulties, the first one is the absence of residents of a home. Smart home system or home automation is always designed based on the need of people such as when a light or air conditioner will start. When the temperature of a room increases above a certain level or the light intensity of a room decreases below a critical level, the air condition or light turns on automatically. It is controlled by the microcontroller. But, most of the cases, the temperature of a room rises high during the day when people usually go to their office and children go to their school. In this paper, it is considered. We not only think about the fan or air conditioner or light, but we also think about the elevator, motor and other utility systems. Also, safety is added to our design approach. Automatic motor running during the empty state of a water tank and automatic elevator controlling when people need to use it is also considered in this paper.

We have considered our home automation system in two parts. One is an interior home appliances controlling system using a microcontroller and the other one is exterior i.e. building electric appliances controlling system. In the interior home appliance system, we have considered microcontroller to control different appliances using Grid-eye sensors. On the other hand, for controlling building electric appliances, we have considered PLC.

A. Interior System Design

1) System architecture: We have used a light intensity sensor BH 1750 to interface it between microcontroller and light bulb. BH 1750 sensor is set in all the rooms of the home to control the on/off of the light. When the light intensity of a room decreases below a critical level the microcontroller sends a signal to turn on the light bulb. But when there is no person in the room, the microcontroller also sends a signal to turn on the light bulb which is not a desirable design for us. So, we have also interfaced a Grid-eye sensor to detect the presence of people in the room. The microcontroller considers two cases; one is the presence of people in the room and the other is the condition of the room. As a result, our system will be smarter and will save fuel or energy costs. Moreover, safety systems are also included in this design. Manually starting the/stopping system using android apps or using a smartphone can be easily interfaced with this system to control the home appliances when anyone wants to turn on/off home appliances if necessary.

The system consists of a microcontroller which is interfaced with a GSM module. All the utilities are controlled by this microcontroller. Also, some sensors like gas/smoke sensor, temperature sensor are used to keep home safe, and if any mishap happens, then SMS is sent to the user's mobile indicating the temperature or gas presence in the room. In the system, we also consider auto open/close of the doors and windows of the rooms. HC-SR501 Infrared PIR Motion sensor is proposed to use in this case. Also, power generator, elevator, water heater, motor all are considered to automatically on/off upon the presence of people in the home.

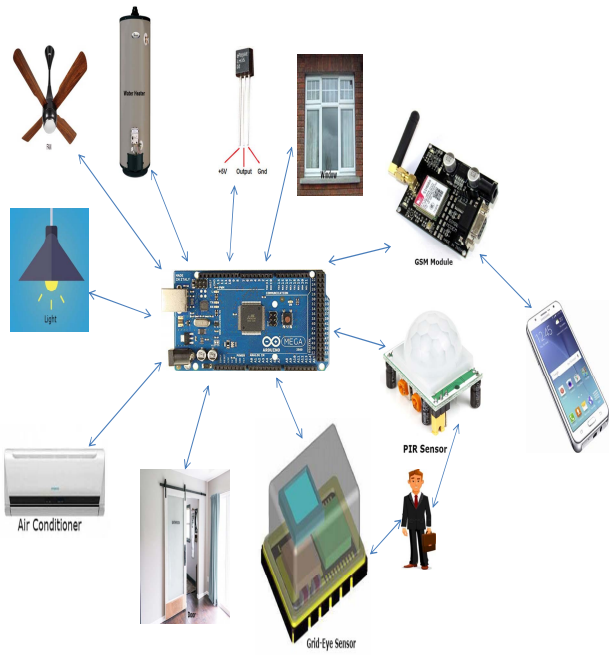

Fig.1. System architecture (inside a flat).

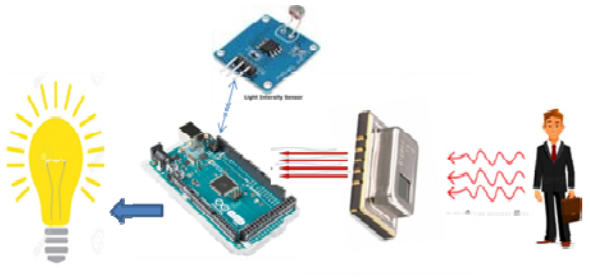

Fig. 2. Utility (Light) active.

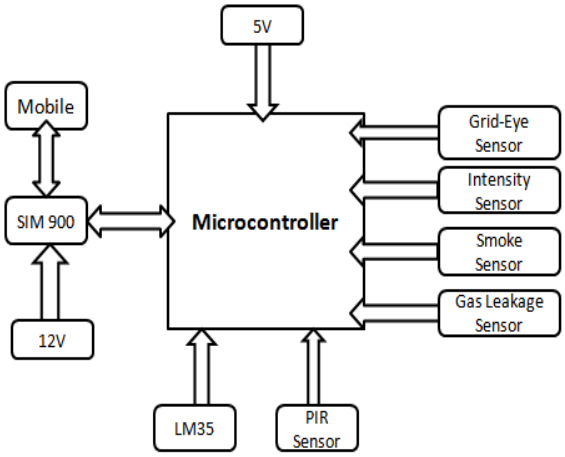

Fig. 3. System Diagram.

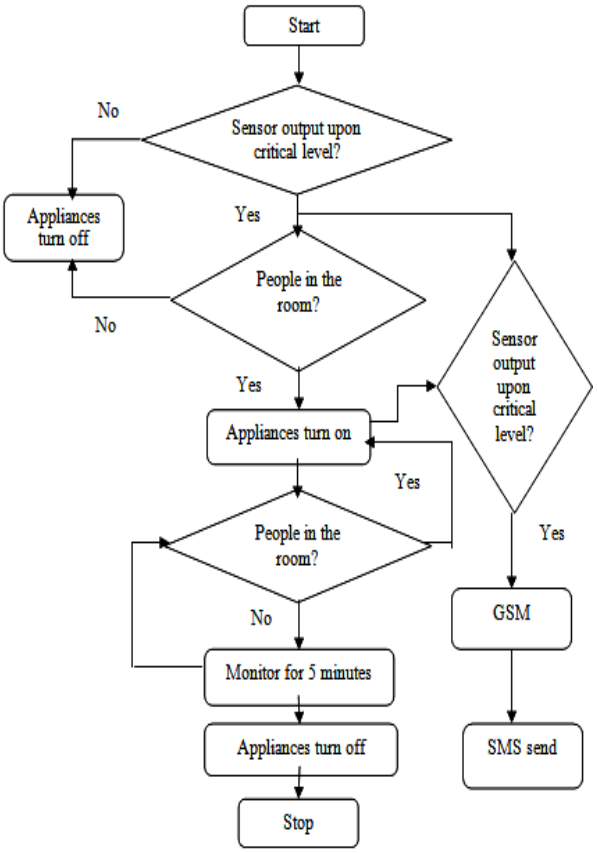

Fig. 4. Flow chart of the system.

2) 4-Room Model: We have implemented our smart home system by considering a 4 room model. In this model, we have used only one microcontroller which is put in the centre of 4 rooms. Four LM35 temperature sensors, four Grid-eye sensors are considered in this 4-room model. All of the 8 sensors are connected to the microcontroller. The microcontroller is programmed using Arduino IDE software. The lower limit of the LM 35 sensors is set at 18ºC and the upper limit is set to 40ºC in the microcontroller. The lower limit is on the condition of a fan, and the upper limit is for fire warning. The Grid-eye sensors are used to detect the presence of the people in the rooms.

When a person enters in room 1, the fan of this room switched on automatically since the temperature was 28ºC of the room on that day. The fan continues to remain on condition till the person present in the room. The fans of other rooms are in off condition since no one present in these rooms. When the person left room 1, the fan keeps running, and then it will stop after 5 minutes (Condition is set in the microcontroller). If the person now enters in room 2, the fan of room 2 becomes on, and it will also take 5 minutes to stop after leaving of that person. The same result will be found for the other 2 rooms. As a result, the person does not need to use android apps or Bluetooth or internet, in this case, to turn on/off of any electric appliances.

3) Programming the microcontroller: For the 4-room model, we have programmed the Arduino AT Mega 2560 microcontroller using Arduino IDE software. The programming is compiled following the flow chart of Fig.5. The four LM 35 temperature sensors have been connected with four analog pin A1, A2, A3, and A4 of the microcontroller. Also, four HC-SR501Infrared PIR Motion sensors instead of Grid-eye sensors are used which are connected with digital input pin 11,12,13, and 14. Both the LM 35 connection pins and PIR sensor connection pins are defined in the programming. When a person leaves from a room, the pin output of PIR becomes low. Since we set a delay (300000), the microcontroller monitors 5 minutes and makes the appliance turn off after it. We use "if ….else" loop for input to the microcontroller from LM35 sensors, and the upper critical value of temperature sensors is set to 40 ºC (inputPin >=40). A SIM 900 GSM module is interfaced, and AT+CMGF=1 command is used for sending SMS when LM 35 output goes over the upper critical level. The mobile number is set by using AT+CMGS command.

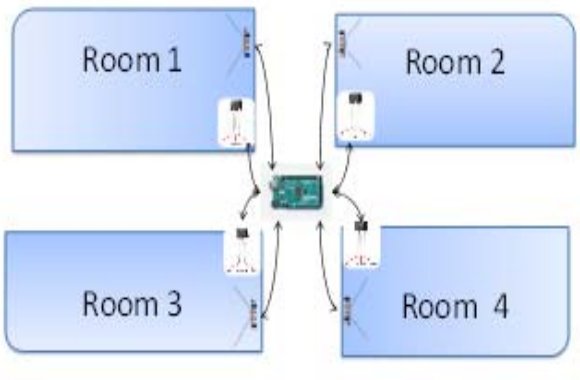

Fig.5. Four-room model

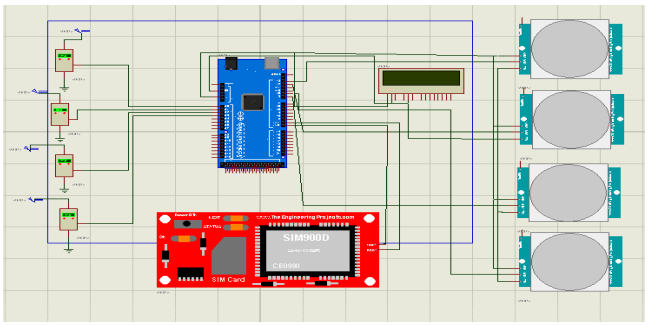

Fig. 6. Proteus simulation of the 4 Room Model.

4) Simulation: Using Proteus simulation software, we have simulated 4-room model which is shown in Fig.6. Also, fire warning to the mobile is simulated by using SIM900 GSM module in the simulation.

B. PLC based Exterior Automation

In our designed system, exterior electric machines such as water pump, generator, and elevator are controlled by using PLC. Though PLC is used especially in the industrial automation system, in the high rise building PLC can be used because of its reliability. We think about the automatic control of water pump, elevator, and generator such that our electricity cost minimizes.

a) Water Pump Control: For controlling water pump, two water level sensors (I1 and I2) are utilized. Ultrasonic sensors (HC-SR04) can be used to determine water level in the tank [23]. I1 is the upper water level indicating sensor and I2 is the lower water level indicating sensor. When the outputs of the two sensors are low, the water pump starts, and when the outputs of the two sensors are high, the water pump stops. In this case, when I1 is high, I2 becomes automatically high. Hence, when I1 becomes high, the water pump stops. Data transmission to control the water pump was provided by the PLC. A flow chart is shown in Fig.7. Simulation of this flow chart is shown in Fig. 8 where using Siemens LOGOsoft Comfort software is used.

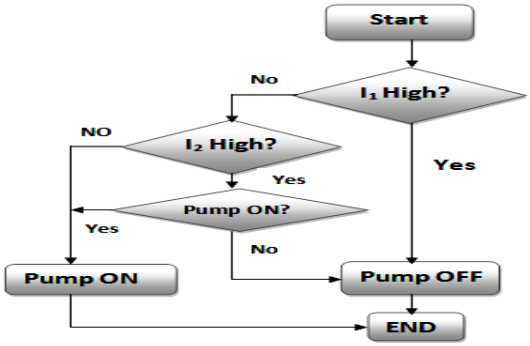

Fig.7. Flow chart of water pump control.

Table I . Truth Table Of Pump On/Off.

I1	I2	Q1	Q2	Pump (On/Off)
0	0	1	0	On
0	1	1	0	On
1	1	0	1	Off
0	1	0	1	Off
0	0	1	0	On

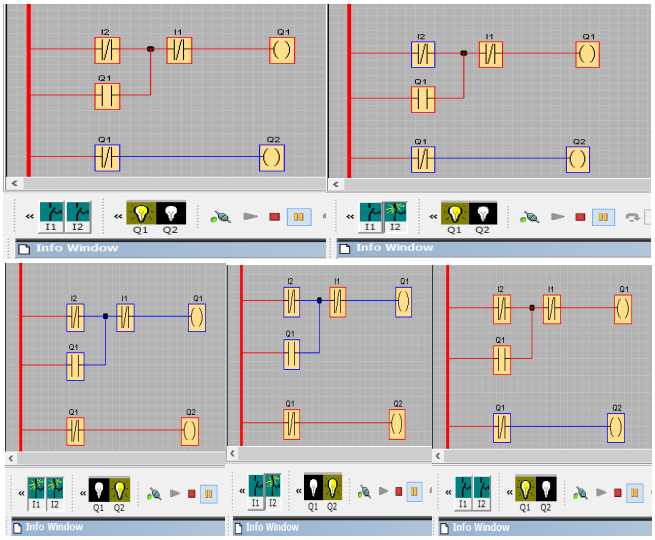

Fig. 8. The water pump on/off simulation.

b) Elevator and Generator controlling: The elevator and generator of a building will only start if people present in the elevator. To demonstrate this case, we only consider the on/off of a generator connected to the elevator during load-shedding. We have implemented our desired design using a load sensor connected to the elevator. The load sensor is used to detect the presence of a person in the elevator. When the load (weight) is applied to the base of the elevator the output of load cell will be high.

The elevating system is operated and controlled by stored programs in the PLC and is designed as an on-off controller. The operation of a power generator connected to an elevator is also controlled by PLC. Here we will design a controlling system of elevator and generator connected to PLC.

In our designed system, several cases are considered to control the generator connected to the elevator when grid electricity is not present.

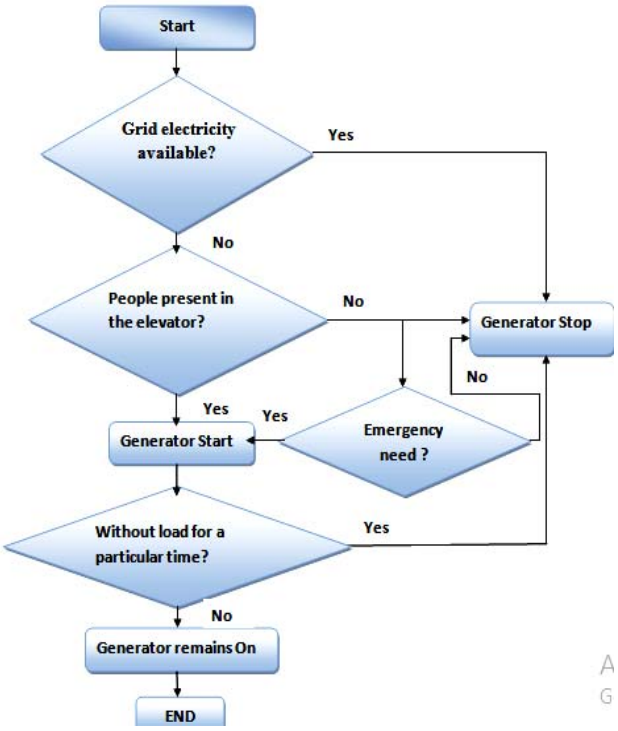

Fig.9. Flow chart of controlling elevator and generator connected to it by considering the presence of people.

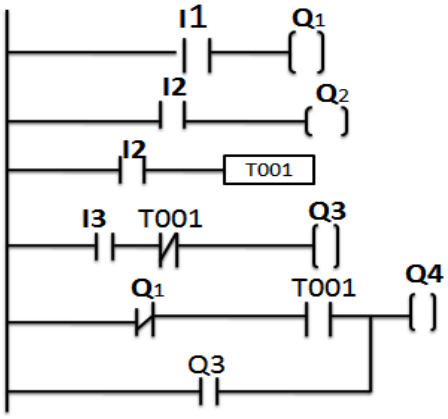

Fig.10. PLC ladder diagram for controlling generator connected to elevator according to the flow chart of Fig. 9.

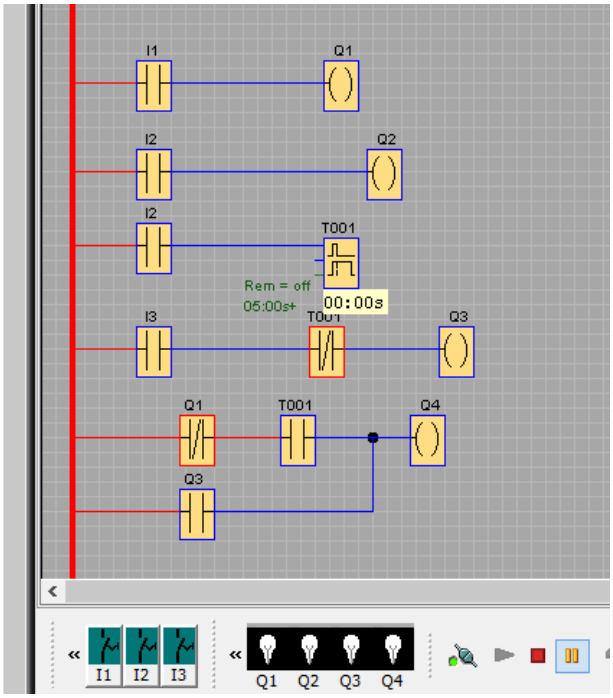

Fig.11. Simulation of controlling generator connected to elevator depending on the presence of person.

The ladder diagram using "Siemens LOGOsoft Comfort" software for the flow chart of Fig.9 is shown in Fig.12. In the ladder diagram,

- I1 indicates whether electricity supplying from the grid or not.
- I2 indicates whether people (load) present in the elevator or not.
- I3 indicates emergency needs (when anyone needs to run the elevator when both electricity and people (load) in the elevator are absent).
- T001 is an off-delay timer that keeps a generator running for 10 second after people leave the elevator (during load-shedding). As a result, another person can ride on the elevator within this time.
- Q1 output indicates the presence of electricity.
- Q2 output indicates the presence of people (load) in the elevator.
- Q3 indicates emergency need.
- Q4 output indicates the on /off of the generator connected to the elevator.

IV. Result and Discussion

Using this automation system, the utilities of the home automatically turn on/off considering the presence of people in a room and the condition of the environment. As a result, people need not concern about on/off of any utilities even when they out of a home. We have implemented a prototype of a smart home for 4-room model using microcontroller, sensors and SIM900 GSM module. Also, automatically opening system of the doors and windows have been interfaced with our designed prototype. It is possible to implement this system for a multi-room house even in the whole building. Moreover, the safety sensors will give important warnings by sending SMS to the mobile phone about any danger in the home via the GSM module. By using smoke and gas sensor and GSM module, we have implemented and verified safety system of the designed home automation. Also, controlling of an elevator is implemented using a Siemens PLC module and TIA PORTAL v12 software. In the future, we will investigate transactive control of demand response for flexible loads which can be used for energy efficiency programs [24], [25].

V. Conclusion

The main advantages of the proposed system are the low cost and user-friendliness. Another main advantage of this system is flexibility and automation. Though there are many smart home system using IoT, Bluetooth, Zigbee, cloud-based, smartphone-based, Tablet or PC based, among them this designed system is simple, low cost, energy saving and flexible for common people. People will feel relax and free from the manual switching system. Even people need not use any mobile apps to turn on/off of any utilities in normal situations. We have used PIR sensors instead of Grid-eye sensors in the Proteus simulation to detect people in a room since the library file for Grid-eye sensors is not available. We do not make an android app to control the utilities (turn on/off) when people want to change the pre-set condition of on/off of any utilities in any particular situation. Many papers have already published to control home appliance using android or wireless network, and people can use any convenient system like an android app or Bluetooth or IoT in this case.

***Abstract*—Data warehouse is an inseparable part of modern business but the amount of data it stores is huge and growing so fast, the queries of the business leaders it processes have become very sophisticated as well. Data warehouse needs to response to those queries with high quality data having less response time but the major challenge for that is the scale of data and nature of the queries involved. It's very hard to access the required data set with minimum response time in data processing as the data warehouse needs to perform analytical operation on a large set of data analyzing sophisticated queries. This paper introduces a new data warehousing schema that constructs a multidimensional relation tree hierarchy, changing the traditional use of relational database, with partitioned database in its every level instead of any individual data. This schema allows data warehouse to partition and process a large data part by part in a small batch to minimize the response time and stores summarized data to increase data availability in query processing. Allowing easy and fast access to the required set of data, this schema improves the performance and the decision making ability of the data warehouse.**

Keywords—Data Warehouse, Data Warehouse Schemas, Data Partitioning, Data Warehouse Architecture, Data Quality, Response Time.

I. INTRODUCTION

Data warehouse technology has been a matter of interest and of paramount importance in today's business. The business communities and organizations are becoming more dependent on their ability to quickly access, easily use, efficiently maintain, quality and timely business information which they need to achieve their goals [1]. But the success of the data warehouse depends on how much the warehouse system is related to business intelligence. So, while data warehouse implementation, the system architecture should be designed and confirmed by the decision makers first [2]. Many data warehouse systems fail to fulfill its requirements to help in strategic decision making as the warehouses fail to understand the requirements of the business leaders.

The data warehouse is a repository of information collected from multiple operational sources, stored under a unified schema. Data in today's business are growing so fast making it very difficult to handle them and introducing many difficulties in data processing. The requirements of the business leaders have been complicated with the overgrowing business process and the larger data set [3]. So it is not just the requirements of the business leaders a warehouse has to deal with, it is also the size of the data stored in the warehouse that needs appropriate maintenance too. Efficient query processing is very important for any data warehouse system as the decision makers want the warehouse to answer complex queries with minimum response time. The warehouse stores a large amount of data and process much more complex queries, thus the response time is much higher. Most of the data warehouses are inefficient, consuming more resources and taking more query response time because of the volume of the data and given nature of the queries [4].

Data quality is another major concern for a data warehouse system and it plays an important role in business process [5] as the decision makers need appropriate data to take actions. The overgrowing data make it very difficult for a data warehouse to provide the expected data quality [6]. Data quality needs to be monitored, including timeliness and completeness of the data stored in the warehouse [1]. Poor data quality can have a severe effect on the effectiveness of the data processing operation but the problems of data quality are often being ignored in the process of data warehouse construction and utilization [7]. The quality of data is defined by its accessibility, availability, and acceptability to the users and should be retrievable with minimum response time. Many data warehouses fall apart just because they fail to maintain easy accessibility, enough availability, and acceptability of that over growing data to the users. Without easy access to enough data, a data warehouse is never going to be able to fulfill the needs of the business leaders.

After the introduction, the rest of the paper is organized as follows: Section II describes the aim of this work and section III describes the related work. In section IV, we propose a data warehousing schema where section IV(A) describes the methodology and section IV(B) point out a key challenge of the proposed schema followed by section IV(C) dedicated to the analysis of the schema. Finally, section V presents the conclusions and future work direction.

II. AIMS OF THE STUDY

This paper aims to introduce a data warehousing schema trying to overcome the difficulties of the data warehouse technologies using horizontal data partitioning in the warehouse design. Business organization needs the data warehouse to process certain set of data first to perform efficient analytical operations for fast and timely decision making [2] and certain queries in a data warehouse requires only a portion of data to be processed and the query response time can be minimized by using different portion of data for different type of queries [8].

This schema uses the data partitioning technique in data warehousing to reduce the query response time having fewer

data to access to process. We are going to apply the horizontal data partitioning to the fact tables where each horizontal partition will have a subset of tuples from the respective relation table. By reducing irrelevant data access and using parallel execution of OLAP query, horizontal partitioning will reduce the query execution time [8]. This schema will increase the accessibility and availability of data with additional attributes in relational tables to improve the data quality and to minimize the response time of the system considerably.

III. Related Work

There are three different schemas present in the warehousing technology to design a data warehouse: star schema, snowflake schema and fact constellation schema [9][10]. However, they are not that different from each other in designing a data warehouse. In star schema, one fact table shares multiple dimensions. Both Snowflake and fact constellation use the same concept as star schema except snowflake schema divide dimension into sub-dimension and fact constellation allows multiple fact tables to share the same dimension to reduce data redundancies. Therefore, technically speaking, those schemas are designed for one consideration only, fact table shares dimension tables to describe those facts. In these schemas, the size of the fact table is never considered but the over growing data is a major concern to the modern business. A huge amount of operational data are being stored within a very short time and these schemas are storing this huge data in a single fact table without considering the size of that table. Therefore, it has become very difficult for the existing data warehouse technologies to perform analytical operation on such a large data set and thus fail to provide the expected outcome.

Author(s) [8] described how data partitioning can be of use to maintain the large volume of data and, using partitioned data, the response time can be minimized. But they partitioned both the dimension tables and the fact tables, which results in a huge number of partitioned tables. But this schema will partition just the fact tables not the dimensions and those partitioned fact tables will be related to a specific dimension by some extra attributes. Those extra attributes will increase data availability in the dimension table and result in fast response to certain queries having quick access to require data.

IV. Proposed Schema: Subject Oriented Data Partitioning

This paper proposes a new data warehousing schema using the data partitioning technique on the large scale of fact data. Using horizontal partitioning, this schema stores the facts as small fragments of data and processes them separately. The partition is based on the records of a specific dimension and the choice of that dimension table used in partitioning the fact table plays an important role on the overall performance of the data warehouse system.

The facts are partitioned based on a specific dimension, not all dimension tables take part in the partitioning process. Some dimension tables just describe the facts as they are supposed to do. This schema doesn't just partitions the fact, it allows the warehouse system to hold a relational table, partitioned fact table, within an attribute of another relational table, the respected dimension. This schema also allows the inner relation to have its own structure and this way creates a relation tree hierarchy. In this schema, we are referring to those dimensions that partitions the facts as 'Parent table' and the partitioned fact tables as the 'Child table' of that hierarchy.

In this schema, the parent table has an additional attribute to its attribute set for every type of facts it partitions and the data of that attribute is an abstract value from its corresponding child table. The parent table may have several records and the number of parted fact tables will be as much as the records of that parent table. And as they all belong to the same attribute, they will have the same attribute set and same structure format for a specific type of fact.

A. Methodology

We have talked about how the data warehouse schemas design a data warehouse having dimensions describing the facts. Consider that the Sales, Ratings & Reviews are the operational fact tables and Product, Store, Location & Customer are dimension tables used to describe these

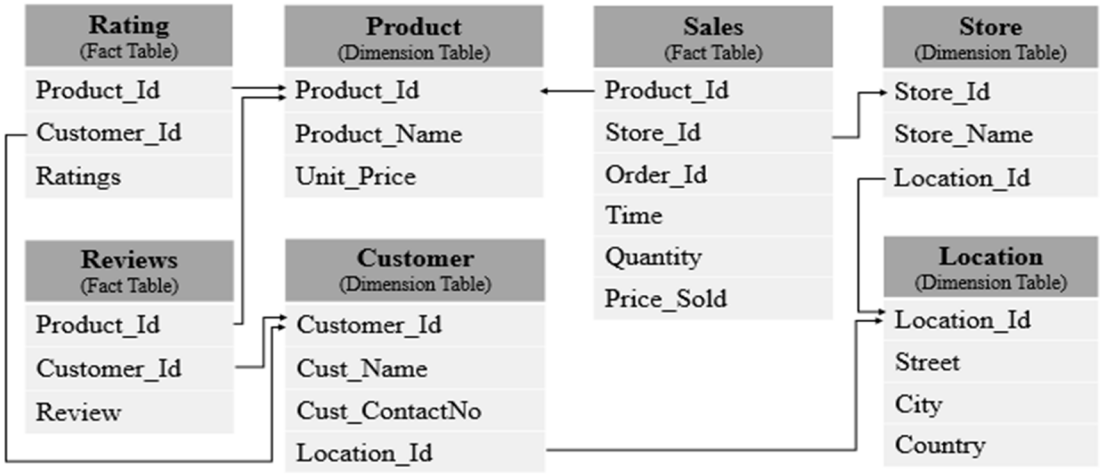

Fig. 1. General design schema of a data warehouse for Sales, Ratings & Reviews.

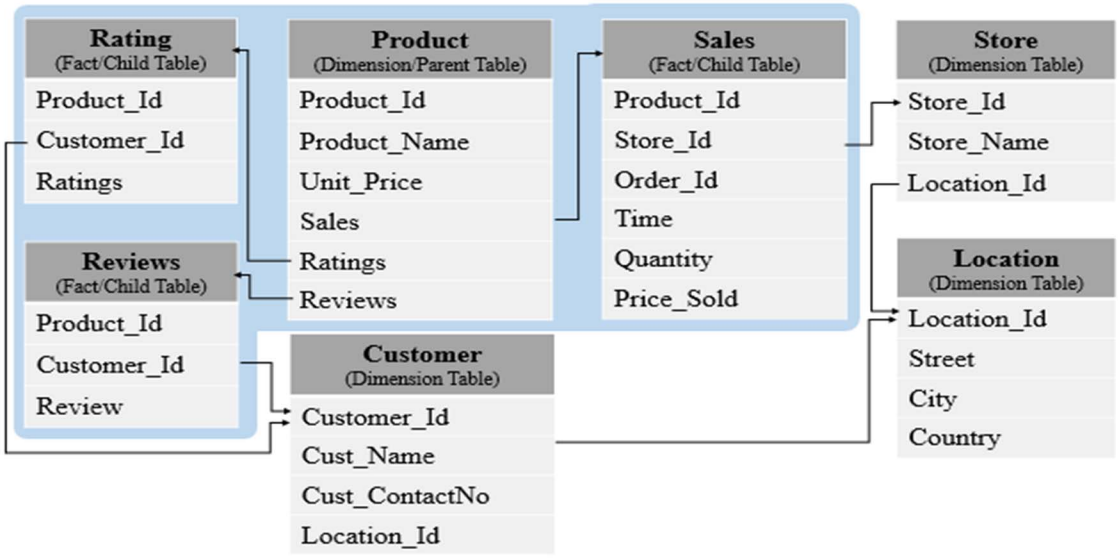

Fig. 2. Proposed schema of a data warehouse for Sales, Ratings & Reviews.

operational facts in a data warehouse and the attribute sets for these relations are-

Product: (Product_Id, Product_Name, Unit_Price)
Store: (Store_Id, Store_Name, Location_Id)
Location: (Location_Id, Street, City, Country)
Customer: (Customer_Id, Cust_Name, Cust_ContactNo, Location_Id)
Sales: (Product_Id, Store_Id, Order_Id, Time, Quantity, Price_Sold)
Ratings: (Product_Id, Customer_Id, Ratings)
Reviews: (Product_Id, Customer_Id, Reviews)

Fig. 1 describes the data warehouse for Sales, Ratings, and Reviews having the dimensions Product, Store, Location, and Customer to describe them using the existing data warehousing schemas. However, think differently, it would seem like these facts somehow belongs to a product. What it means is that sales, ratings or reviews should be part of a product, without a product there will be no sales, ratings, or reviews. Again, while retrieving the data record of a product, someone would like to get its sales, ratings or reviews as well. Because these facts are of a product rather than the product of these facts. Therefore, this method considers that the Product relation must have the sales, ratings & reviews record in its relational table and to do that, the Product relation must have additional attributes for these facts. Then the Product relation would be-

Product: (Product_Id, Product_Name, Unit_Price, Sales, Ratings, Reviews)

In this case, the Product relation does not describe these facts. These facts describe the corresponding attribute, with abstract data stored in their attribute field, of the Product table. Fig. 2 shows the data warehouse of these relations using the proposed schema. This design is the same as the general design schema except the relationship shown in the highlighted part of the figure. Here, the Product dimension table, the parent table in this structure, shares the facts to describe its Sales, Ratings, and Reviews attributes with appropriate data.

In this design, the parent table and the fact tables are not connected with the same attributes in both relations as they were in the previous design. Although they both have that common attribute, they are not bound to be connected. This method allows the parent table to contain the fact tables within its respected attribute field to describe the value stored in that field. So the facts will be partitioned into separated tables with the help of the ETL tools respect to the data stored in the parent table, e.g. in this design, the operational facts of sales, ratings or reviews will be partitioned into separate smaller in size fact tables as per the product that those facts describe. Therefore, the Sales, Ratings & Reviews attributes of the Product relation will have their own attribute set to describe their data recorded in the warehouse. To understand the relationship between a child table and its parent table, consider the two following relations-

Product: (Product_Id, Product_Name, Sales, Unit_Price)
Sales: (Order_Id, Quantity, Price_Sold)

Here, the Sales relation is dependent on the Product table as it describes the Sales attribute of the Product table. In the proposed schema, these two attribute sets are described by the following relation.

Product: (Product_Id, Product_Name, Sales: (Order_Id, Quantity, Price_Sold), Unit_Price))

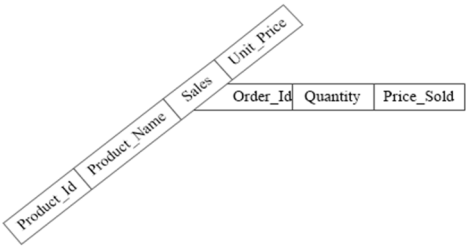

Fig. 3. Basic relationship of the proposed schema.

Fig. 3 shows the basic structure of the relationship used in the proposed schema but the inner attribute set does not actually belong to the respected attribute of the parent table. It actually belongs to the data field or record stored in that attribute, this is the main difference of this schema with the existing schemas. In existing schemas, all the relationship between different relational tables was record to record. This schema uses the relationship of record to table rather than record to record, a specific record of the parent table with the corresponding child table. The structure of this relationship is shown in Fig. 4.

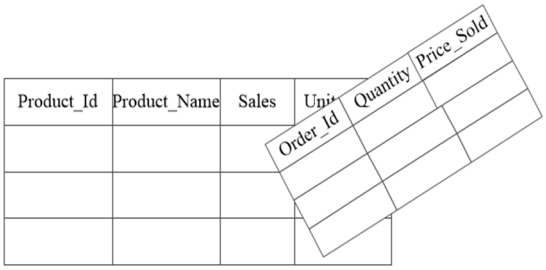

Fig. 4. Record to table relationship of the proposed schema

This schema designs the data warehouse a way that allows the parent table to store an abstract data to its attributes having an attribute set related to it. In this schema, the data stored in that attribute field is very important as this data is going to stand for its corresponding child table in data processing. So, the type of this data must be chosen carefully. To add additional attributes and selecting data for these attributes in the parent relation, this schema uses various data processing operations. Data integration and transformation operations allow to integrate different data sources and adding extra attributes to relations transforming data into appropriate form [11].

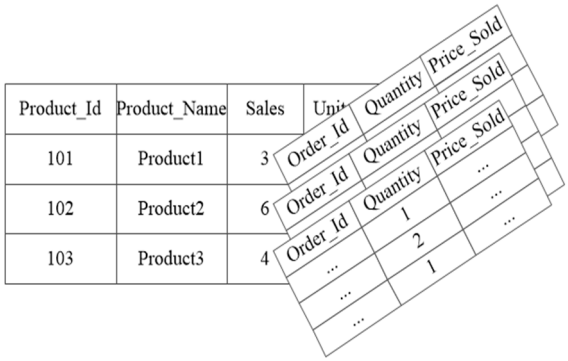

Fig. 5. Record to table relationships & retrieving the attribute value

Using the structure shown in Fig. 4, we are allowing the Sales attribute of the parent table to distribute the total sales to every product record and a partitioned Sales table in every record field of the Sales attribute. Fig. 5 shows that the sales attribute hold a relation table within its every record field and that record field itself stores a value. This value represents the whole table residing with it within that field. In this relationship, this abstract value is the total sales of that specific product. This structure ensures that if there is no record of a specific item in the parent table, there will be no facts stored in the warehouse corresponding to that item. Means no unnecessary facts to bother with.

B. Selecting the Parent (Dimension) Table

This schema partitions the facts according to the records of a specified dimension and the type of data stored in that dimension (parent table) have to be of great importance to the decision makers. Otherwise, the partitions will be of no use. So, the selection of the dimension table is very important in this schema. Author(s) [8] presents a greedy algorithm that select the best dimension table to partitions the fact table based on the queries asked most but, in this schema, the dimension could be selected directly by the choice of the decision makers too, as they might know what would be the best for them.

C. System Analysis

The Design of a data warehouse is an important part of warehousing technology. Success depends on that. But the most important thing that concerns most to the business leaders is the quality of the data and response time of the warehouse to different queries. To improve data quality and response time, a data warehouse needs to provide an easy and fast access to most required data and the data availability must be high but these both requirements depends on how the system is designed and how the data are interrelated. In general, a data warehouse stores data as fact and dimensions and relate them together with different relational key, with a similar type of attributes in both relations, mostly to reduce redundancies.

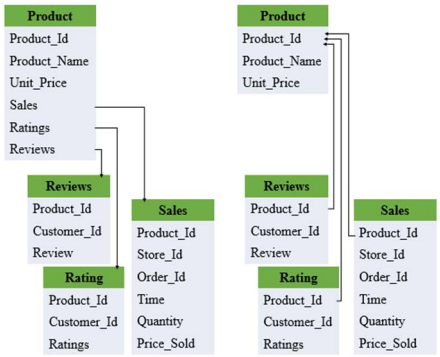

Fig. 6. Relation tree hierarchy of the proposed schema (left) & general relationships between relational tables (right).

Fig. 6 shows a general comparison of the relationships among different relational tables and how the proposed schema is different from the existing schemas. The relation tree hierarchy of the proposed schema uses the record to table relationships whereas the existing schemas use the relationship of record to record. The proposed schema partitions the facts into several child tables as per several records of the parent table and connects these child tables with their corresponding attribute data. So every attribute of the parent table containing an abstract data is related to a specific child table that the abstract data comes from.

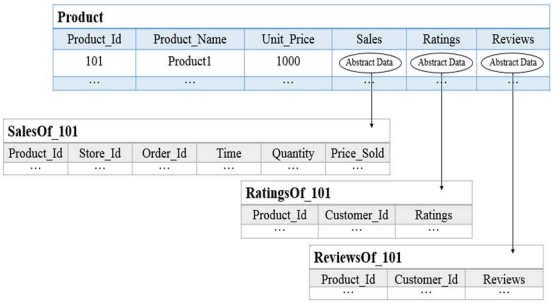

Fig. 7. Relation tree hierarchy of the Product relation.

Fig. 7 describes the relation tree hierarchy of the Product table having sales, ratings, and reviews as child tables in the hierarchy. As different child tables are related to different product record, they are distinct in a specific way, here every child table bear the 'Product_Id number' (could be anything that identifies distinct product) of the product they belongs to, and that allows the warehouse an easy and fast way to find the data set needed for specific query response. This figure describes the relationships of just one product with its child. The Product table will have the same relationship for every product of it.

Fig. 8 describes the general data distribution and the relationships between the fact tables and the dimension table. In this schema, every record of the fact tables is individually related to a corresponding product record of the dimension table using a similar attribute in both tables. In the proposed schema, operational facts (e.g. Sales, Ratings and Reviews) are partitioned as per every product in the dimension table and related to their corresponding product through a specific attribute. So, finding the data of a specific product would require less time as it would not need to bother with unnecessary data.

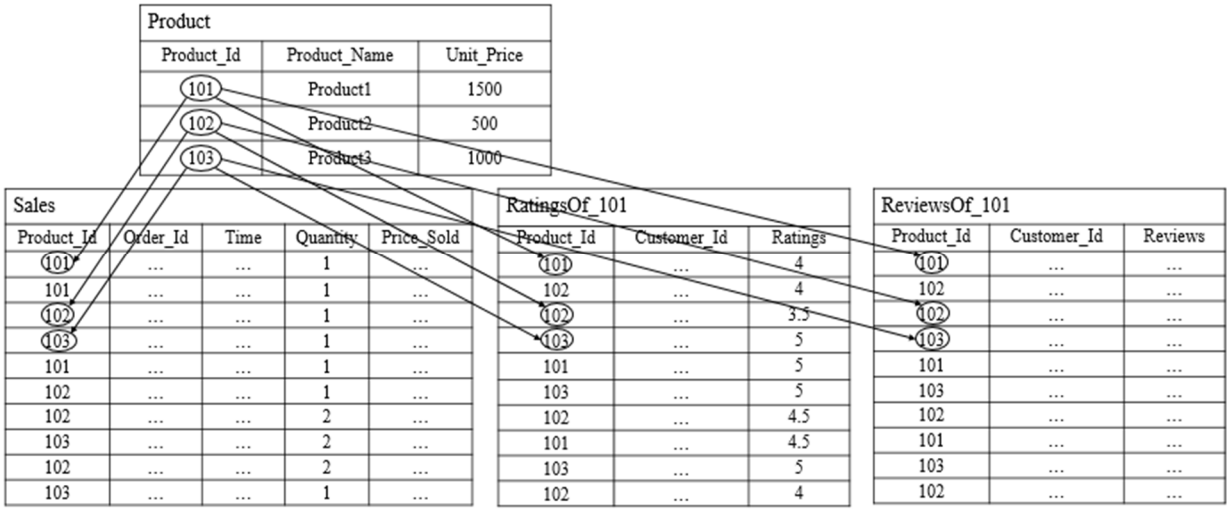

Fig. 8. General data distribution in a data warehouse.

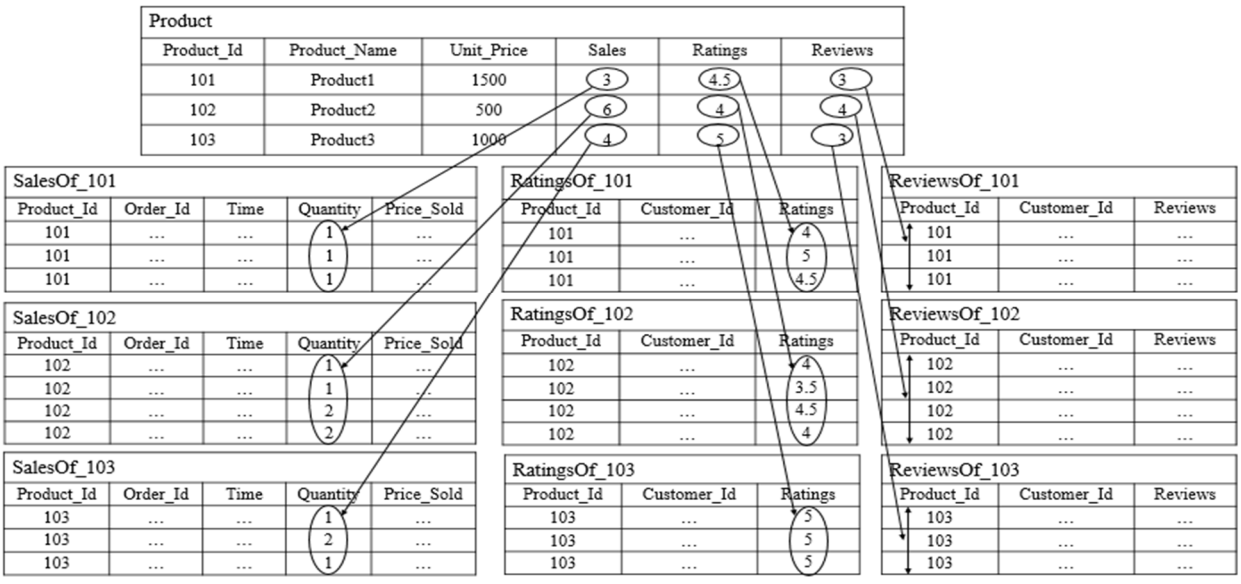

Fig. 9. Data distribution in a data warehouse according to the proposed schema.

Fig. 9 shows the distribution of operational facts among different child tables as per the records of the parent table. This figure shows the data distribution according to a major subject or entity. The Product table stores an abstract data to its specific attributes collected from its child tables. In this design, the Sales attribute gets the total sales quantity, average rating for Ratings and total review count for Reviews from their respected child tables.

This schema has additional attributes to a specific dimension table for every type of facts related to that dimension and these attributes record an abstract data that represents the child fact table related to it. So more data are available in the dimension table and they are easy to process to response certain queries. On the other hand, the child tables are related to different items of the parent table and are uniquely distinguishable, so these child tables are easy to access. Above all, as the facts are partitioned into small parts, they take less time to be processed.

In this schema, the additional attribute of the dimension table increases data availability and gives a complete view of data in the dimension table. As they store summarized data, they are easy to process as well. At the same time, by allowing the data warehouse to store fact tables within the dimension table, this schema increases data accessibility. As the facts are partitioned into small parts, the data warehouse is required to process less data to get the most required information for certain queries with minimum response time.

On the other hand, to design the relation tree hierarchy and the form of the abstract data, this schema is dependent on business intelligence along with other requirements of the decision makers. So, the data warehouse is more connected to decision makers than ever. And as this schema connects the warehouse and the decision makers more closely, the data warehouse is more able to meet the requirements and demands of the decision makers and helps better in strategic decision making with high quality data and improved response time.

V. Conclusion & Future Work

This paper proposed the foundation of a new data warehouse modeling schema. This schema overcomes the general thinking of designing a data warehouse where dimension describes facts. This schema uses the operational facts to describe certain attributes of a dimension and distributes those facts among the records of that dimension. This schema partitions the facts horizontally and results in several small fact tables. Those small fact tables are related to attributes, additional attributes for facts summarization, of a dimension table that increases the data availability in the dimension table. Again, the data warehouse requires less time in response to certain queries as it requires to process a small set of data. This schema also allows easy and fast access to data as they are uniquely distinguishable. Therefore, comes up with better performance in providing high data quality with faster response in various query processing.

However, we are working on some challenges we have come up with like the connection or relation between a child table and the specific record of its corresponding parent table, which is the main structure of this schema, and the common view of all the child tables of the same fact in the relation tree hierarchy. Keeping all these requirements and challenges in mind, we will carry on further work with this schema.

***Abstract*—With the advent of computational intelligence, the analysis of medical data using machine learning techniques benefits accurate classification of different health diseases and disorders. However, disorganization and variability of data make the job difficult. This paper has streamlined an ensemble learning approach for classification of low back pain disorder based on spinal abnormality data of 310 patients with 12 features. To overwhelm the misleading effect of inappropriate attributes, most influential features are identified using evolutionary feature elimination method. Experiments are performed in both way– with or without feature filtering. The basic machine learning algorithms used in the work: Logistic regression, Decision Tree, Naive Bayes, and in addition to the Random Forest ensemble learning method. Random Forest classifier, as expected, is recorded to exhibit the best accuracy of 94% over other classifiers.**

Keywords— Machine Learning, Feature Selection Random Forest, Low Back Pain, Lumber spine Disorder.

I. INTRODUCTION

Low Back Pain, abbreviated as LBP, is a very frequent health issue that affects people from all ages, younger to the elderly [1]. Almost 80% of adults population suffer from low back pain problem at some points in their lifespans [2]. It is reported as the single leading cause of job-related disability and a major contributor of preventing people from attending workplace as well as their daily activities. According to the Global Burden of Disease (GBD) Study report, low back pain is one of the top ten high burden diseases, which leads over HIV (AIDS), lung cancer, tuberculosis, chronic pulmonary disease and preterm birth complications [3,4]. The sufferings and magnitude of LBP disorder dispense a catastrophic effect and become a worldwide problem. In 1990, a study places low back pain in sixth position of burdensome maladies in the United States whilst in 2010, it ascended to third place, with heart disease and chronic pulmonary disease on the top. Meanwhile, low back pain prevalence in developed countries is reported to be up to 85% [2,4].

With the fast development of computational intelligence, researchers are paying attentions on prediction of different diseases from medical data. As low back pain, becoming global fatal problem, got concern of machine learning experts to identify abnormal patients analyzing theirs spinal region data. Physical test or examination and observation in historical patterns of signs and symptoms in a diagnostic view may assist the medical professionals in determining the abnormal patients [5]. In the work, we mainly focus on different angles and orientations of components of lumber spine. The novelty of this work investigates the following challenges: Do all the recorded features, that doctors suspects, are influential? How will the spinal abnormality in a certain region be responsible for low back pain? Which computerized learning techniques would be good for classification of low back pain? To resolve these queries, we first, build singleton machine learning models, then, build ensemble the models in the quest of higher accuracy. It is noted that ensemble models naturally perform better in comparison to single classifiers, but it is not true in all cases [17].

The rest of this paper is succinctly structured into various sections as follows. Section 2 probed some clinical and statistical studies regarding low back pain. The theory and mathematical computations of some essential machine learning approaches is illustrated concisely in section 3. Section 4 represents the spinal data set details and experiments followed by the performance analysis is provided in section 5. Finally, section 6 concludes the study with an interpretation of results and also pledges some recommendations for future research.

II. RELATED WORKS

A good number of studies have been conducted related to low back pain symptoms. Some of the studies find, very likely, to analyze medical aspects and global consequences of low back pain disorder. A few of them work are conducted on artificial intelligence traits.

Lin et al. proposed an advanced clinical decision support system for LBP diagnosis and gain overall performance of 71% in 2006 [6]. Alomari et al., in 2009, introduced a probabilistic classifier on the detection of abnormal intervertebral disc using three feature including appearance, location and context from clinical lower spine MRI [7]. In 2009, Neto and Barreto introduced a comparative analysis of singleton approaches (SVM, MLP, GRNN) and their combination in a ensemble on the detection of vertebral column for LBP [8].

In 2010, a study by Sari et al. proposed two systems for the estimation of LBP level those accept skin resistance and visual analog scale (VAS) values as input. The results from artificial neural network (ANN) and Adaptive neuro-fuzzy Inference (ANFIS) claim good performance in real application [9]. Gosh et al. experimented two approaches in 2011 in this area of detection LBP. The first one is the follower of the experiment of Alomari [7] where Gosh built a heterogeneous classifier as their novelty [10]. In the later experiment, Gosh combines composite features for automatic diagnosis of intervertebral disc herniation of lamber MR

Images. In 2012, Koh et al. designed a two level classification on the same purpose using a CAD framework [11].

A novel research by Mandal adduced a new hybrid machine learning ensembles consisting of Bayesian networks with Tabu search and Haar wavelet and then compare the method with existing models [12]. Later, in 2017, d'Hollosy evaluated three tree-based machine learning methods: decision tree, random tree, and boosted tree on a Clinical Decision Support System (CDSS) [13]. Abhijit et al. in 2017, applied basic machine learning methods- k-nearest neighbor, support vector machine, decision trees etc. They observed that decision tree algorithm yields an accuracy of 90% than other methods [14]. Later on., Kulkarni suggested a deep learning based techniques of classification for LBP disorder in 2017 [15].

III. Experimental Setup

In this section we will reveal the working flow of experiments. The workflow of the proposed methodology is shown in Fig. 1. The first step of the work, problem statement is defined and data collection and pre-processing are done, followed by the step of removing outliers from the data to improve the quality of data. Then the feature selection method is provided to find the importance of the features and select the significant factors. After that, the individual machine learning algorithms are employed along with Random Forest method.

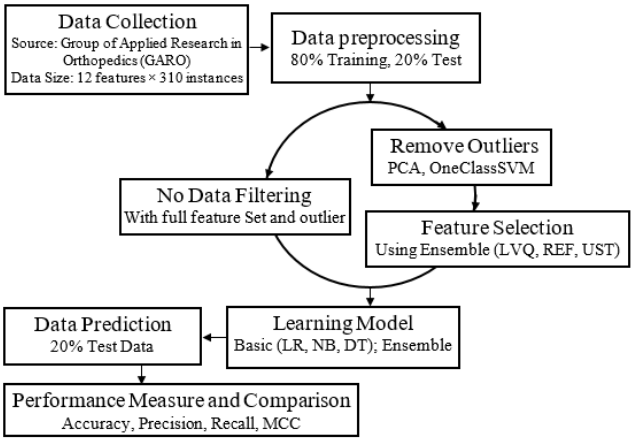

Fig. 1. System workflow of the proposed methodology.

A. Data Set and Data Pre-processing

The data set which is treated in this research is collected from the Group of Applied Research in Orthopaedics of the Centre Médico-Chirurgical de Réadaptation (CMCR) des Massues in Lyon, France during a residence period in spinal surgery. It contains the observations of radiogram of the spine of patients. A total of 310 spinal instances with 12 features are recorded. Each patient is represented with attributes derived from the shape and orientation of the pelvis and lumbar spine. The observations have been target labeled with binary class label either normal or abnormal. The number data items with normal class label is 100 whilst with abnormal class label it is 210. Thus the problem becomes an imbalanced problem. The data set does not contains any missing value. Table I enlists the full set of attributes.

TABLE I. Attributes

Attribute Name	*Type*	*Attribute Name*	*Type*
Pelvic incidence	Numeric	Pelvic slope	Numeric
Pelvic tilt	Numeric	Direct tilt	Numeric
Lumbar lordosis angle	Numeric	Thoracic slope	Numeric
Sacral slope	Numeric	Cervical tilt	Numeric
Pelvic radius	Numeric	Sacrum angle	Numeric
Degree spondylolisthesis	Numeric	Scoliosis slope	Numeric
Class Attribute/Label	Object		

B. Outliers Elimination

An outlier is an observation or data which has far distance from other observations. It deviates serious disturbances on building learning models. An outlier can caused by experimental error, variability in measurements. Whatever is happens, to yield good accuracy, we need to remove the outliers from the data set. There are several approaches to eliminate outliers such as extreme value analysis: z-score, interquantile, DBSCAN, regression model: PCA etc. To determine whether our data set contains outliers or not, we apply PCA in the data set. The output is plotted in the Fig. 2.

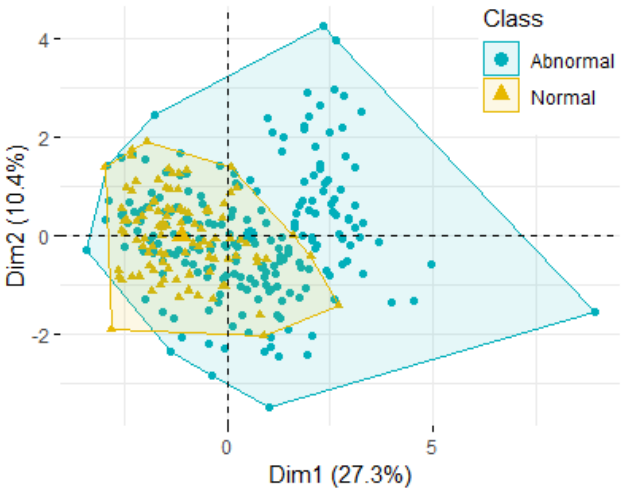

Fig. 2. Outlier projection using PCA.

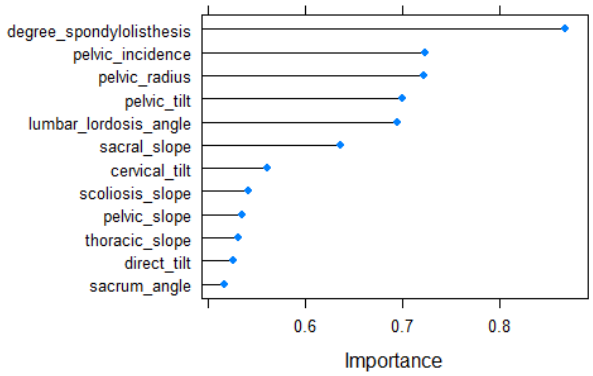
For univariate outlier elimination, extreme value analysis methods work efficiently. As we are dealing with multivariate data, we apply support vector machine algorithm to detect outliers in the data. *OneClassSVM* technique allows us to identify isolated data points in the feature space considering with/without data distribution and expected percentage of outliers using the params:



$$nu\ estimate = 0{:}95 * outliers\ percentage[0; 1] + 0{:}05$$

After the execution of *OneClassSVM*, the data set is clean and outlier free at our confidence level.

C. Feature Selection

Feature selection is an important ML task as excessive, irrelevant and redundant features may mislead the learning model. But feature selection procedures become crucial with large number of features. Moreover, feature selection is a combinatorial problem. There are two types of feature selection approaches: Filtering and Wrapper. Filtering processes find the importance of the features and rank them according to a weight. Meanwhile, wrapper methods search for subsets of features to maximize the computational time.

Wrapper methods start occasionally with empty or complete set of features while filter methods always initiates with full set features. We approach a setwise evolutionary based wrapper paradigm for feature selection. It combines multiple features selection algorithm such as- Learning Vector Quantization (LVQ), Recursive Feature Elimination (RFE), and Chi-Squared Univariate Statistical Test (UST), but these

algorithms worked in a incremental way by adding and removing features. While LVQ searched the best features, RFE worked on the LVQ selected features. UST worked on individual feature to find the best performer. Fig. 3 shows the best features selected that obtained from these algorithms. In the table figures indicates the individual contribution of the features.

Fig. 3. Feature Importance using REF.

Using the concept of voting Ensemble method, finally we have a set of features with majority votes. This is one of the novelties of our work of using ensemble in feature selection step.

D. Classification

We apply basic machine learning algorithm to build classifiers. We built five classifiers including Logistic Regression (LR), Naive Bayse (NB), Decision Tree (DT) and Random Forest (RF) algorithms incorporating feature reduction as our data may contain irrelevant attributes. These algorithms run individually to observe which performs best.

On the purpose of building classification model, first, we employ singleton machine learning algorithms: Logistic Regression, Decision Tree, Naive Bayes. We apply 10-fold cross validation on training data. Following that, we deploy Random Forest ensemble learning method consisting of best performing classifiers in the previous step of the experiment.

After modeling the system we test the performance. We evaluate our model in terms of accuracy, precision, and recall. As our work is supervised, the data set is divided into two set by splitting:

1. TRAIN Set – 248
2. TEST Set – 62

The models are trained using training set data and tested on test set after building the model. We acquired the output in terms of confusion matrix. Then, accuracy, precision, and recall are calculated with respect to the class predictions.

IV. Performance Analysis

In this section we will discuss about the results of the guided experiment. The results and performance have been evaluated using different measures such as accuracy, sensitivity, specificity, and precision [16]. These measures involves the number of true positive (TP), true negative (TN), false positive (FP), and false negative (FN) (defined as in [16]) observations and predictions like:

	The number of
TP	correctly classified positive samples (Class=Normal)
TN	correctly classified negative observations (Class=Abnormal)
FP	incorrectly classified positive instances (Class=Normal)
FN	incorrectly classified negative attributes (Class=Abnormal)

Accuracy is a measure of overall *effectiveness* of the classification model. It indicates the ratio of correct classifications over total observations. It can be calculated as stated Eq. (1)

$$Accuracy = \frac{TP+FN}{TP+TN+FP+FN} \quad (1)$$

Precision is a measure of *exactness* of the classifier and it states the proportion of correct positive classifications over the positive predictions. It can be calculated as Eq. (2)

$$Precision = \frac{TP}{TP+FP} \quad (2)$$

Recall, also called Sensitivity or True Positive Rate or *completeness*, computes how well the model in identifying the positive instances (Class=Normal). It is calculated as Eq. (3)

$$Recall = \frac{TP}{TP+TN} \quad (3)$$

Table II and III depict the summary of results of the Random Forest classification method without and with Feature Selection, respectively. The confusion matrix states TP, TN, FP, and FN values for actual and predicted classes. In comparison, the classification rate in Table III is higher than Table II. This proves better performance of Random Forest classifier with selected features.

TABLE II. Confusion Matrix of Random Forest (Without Feature Selection)

	Predicted Normal	*Predicted Abnormal*
Actual Normal	17	7
Actual Abnormal	3	35

TABLE III. Confusion Matrix of Random Forest (With Feature Selection)

	Predicted Normal	*Predicted Abnormal*
Actual Normal	20	2
Actual Abnormal	2	38

TABLE IV. Comparison of Classification Methods (Without Feature Selection) (in %)

Measurements	***Logistic Regression***	***Naive Bayes***	***Decision Tree***	***Random Forest***
Accuracy	82	79	81	84
Precision	68	62	68	71
Recall	85	90	75	86

TABLE V. Comparison of Classification Methods (Without Feature Selection) (in %)

Measurements	***Logistic Regression***	***Naive Bayes***	***Decision Tree***	***Random Forest***
Accuracy	90	84	92	94
Precision	82	75	86	90
Recall	90	82	90	90

The similar patterns can be seen for Logistic Regression, Naive Bayes, Decision Tree as well. We can observe that from Table IV and V. The tables stated precision, recall, and F1 Score along with accuracy. We observe the highest accuracy of 94% gained by Random Forest ensemble.

It can be observed that the models perform better with feature selection. Feature Selection step of our experiment discards less important features and it may very useful for medical data processing with computational intelligence where huge bunch of data and features are recorded. This experiment answers our research questions as not all the features are useful to consider. However, a patient with low back pain may suffering from other lumber spine issues such as damage of spine due to age, radiculopathy etc. These factors may consider as less responsible for specific deceases or disorders or damages.

In the same experiments we focus on a particular research question which finds the supporting and contradicting trends of the attributes towards the abnormality of lumber spine. disorder. To answer the question, we use the contribution score of the attributes from feature selection step. Table VI summarizes the results. We projected that this information can help to more accurate diagnosis and prescribing the therapy for the patients.

TABLE VI. SUPPORTING AND CONTRADICTING ATTRIBUTES TOWARDS ABNORMALITY

Supporting Attributes	*Contradicting Attributes*
Degree spondylolisthesis	Scoliosis slope
Pelvic incidence	Pelvic radius
Sacrum angle	Sacral slope
Lumbar lordosis angle	Direct tilt

V. CONCLUSIONS AND FUTURE DIRECTIONS

The study shows that an automated system can be implemented in the diagnosis of low back pain. We conclude answering our research questions with experiments. More training data and more efficient algorithm this can be a real life implementation for clinical diagnosis in Bangladesh. Bangladesh medical system can accumulate more clinical data in an organized and structured way where each patient's medical data can be secured which can be later be used in many different studies for other diseases and also incorporate with the existing system for automated classification and detection of those diseases. The research intends an artificial intelligent, in the other, machine learning approach to identify responsible attributes of causing low back pain from the spine. Although the origin of low back pain remains unknown in most of the cases, some frequent occurring symptoms are identified to be useful in this study. This intuits medical professionals to early diagnosis of the low back pain disorder.

***Abstract*—Very few diseases are as deadly as Breast cancer and Lung cancer that causes a high percentage of deaths every year. Data mining approach works quite effectively in diagnosing cancer. This has been possible mainly because of the potential of classification systems that has been improved in a great arrangement in helping medical experts. In this research work, data mining has been applied for the diagnosis of cancer. For the purpose of that, an ensemble method has been used to extract the most important features in detecting cancer and classify the pattern of cancer according to the most influential features. For feature extraction the advantages of Principal Component Analysis (PCA), Pearson Correlation Coefficient (PCC) and Chi Square (Chi2) have been considered using set union operation. By the help of the hybrid model of feature extraction, and classification, Naive Bayes, K Nearest Neighbors, Decision Tree (J48, ID3) classifiers were used to classify the model. Results from individual classifiers have been voted by majority voting to obtain the best possible outcome. k- fold cross validation (10 and 5 folds) and train (80% and 70%) test (20% and 30%) split have been applied to examine the performance of the model(AEEMCD).**

***Index Terms*—Data Mining, Cancer Detection, Feature Selection, Set Union Operation, Classification, Ensemble, Majority Voting, PCA, PCC, Chi2, Naive Bayes, KNN, Decision Tree.**

I. Introduction

Cancer has been one of the most lethal diseases in the recent years. Among women in this world the most common cancer is breast cancer. Men are highly affected by lung cancer. Even though the incidence of breast cancer in developing countries is lower than in Western countries, it is rising rapidly in the particular region. Significant rates of death due to cancer could be reduced in the long term if the cancer is detected in early stages. For best prognosis, identifying cancer cells in early stages is the most critical point. Early stage cancer diagnostic and high sensitive method is a must. Classification and Data Mining methods are effective ways to categorize data especially in the medical field. Computing, and machine learning tools can significantly be used to help solve health care problems by assisting physicians in diagnosing, and predicting diseases in early stage by developing expert systems. Computer Aided Diagnosis (CAD), and medical experts systems, and tools have become one of the foremost research areas in the field of medical diagnosis [1]. In this research work, a few of classifiers are used to detect cancer on their samplings. The precision of these classifiers depends both on their algorithms and how they are trained. In sequence, train them properly using a dataset, the most applicable features of the feature vector have to be taken. In this way, we can increase the efficiency of the classifiers as well as reduce the learning runtime. For this logic, we work to find out the important features of our training datasets and then we use set theorem method on that features to find out the most common features of our datasets.

There are 10 features in the Wisconsin Breast Cancer (Original) Datasets, 32 features in the Wisconsin Breast Cancer (Diagnostic) Datasets and 57 features in Wisconsin Lung Cancer Dataset. All the experiments were performed on WEKA 3.6 [2]. This research work is assembled in these ways: Section II covers the related works on these classifiers and datasets. Section III describes proposed model and followed by the result analysis, and conclusion and future works in section IV, and V.

II. Literature Review

There exist innumerable papers and books demonstrating the convenience of the feature selection process [3], [4].

On the Wisconsin Breast Cancer (original) datasets, the performance of four algorithms of machine learning: Naive Bayes (NB), Decision Tree (C4.5), k-Nearest Neighbors (k-NN) and Support Vector Machine (SVM) where SVM gives the highest accuracy (97.13%) was proposed [5]. All experiments were executed in WEKA data mining tool. The potency of the classifier was evaluated in terms of Kappa statistics (KS), Mean Absolute Error (MAE), Root Mean Squared Error (RMSE), Relative Absolute Error (RAE) and Root Relative Squared Error (RRSE). KS, MAE and RMSE were represented in numeric values. RAE and RRSE were represented in percentage.

A method to extract classification rules from trained Naive Bayes and discussion of its application to breast cancer diagnosis is stated in [6]. The pre-processing of data set that can raise the accuracy of the neural Nave Bayes and the correctness of the rules as some rules may be extracted from human experience, and may be inaccurate were also explained. Laplacian Correction was used when their method got zero probability values. The experiment was carried out in MATLAB (matrix laboratory). The Nave Bayes classification algorithm showed the success rate as around 85-95 percent and the error rate was around 10-15 percent.

A bio inspired model named BATELM was suggested in [7] which combined Bat algorithm (BAT) and Extreme Learning Machines (ELM) on Wisconsin Breast Cancer Prognostic (WBCP) dataset which is a numeric dataset. The concept of BAT and ELM which had many advantages when constrasted to the existing algorithms of their genre had inspired them

to build a model that could predict the medical data with high accuracy and minimal error. The objective of the concept was to predict whether the breast cancer is recurrent or non-recurrent. The accuracy was found to be 95.7% with an RMSE of 0.32. Another objective was to predict the time of recurrence, the result was found to be 93.75% accurate with an RMSE of 0.30.

The collation of Support Vector Machine (SVM), Random Forrest (RF), and Bayesian Network (BN) with and without using k-fold validation techniques was shown in [8]. WEKA machine learning tool was used. Results showed that Bayesian Network (BN) was the best in terms of performance, recall and precision. On the other hand, Random Forest (RF) technique had the optimum ROC performance when compared to the two other techniques. This implied that RF had a higher chance of discriminating between malignant and benign cases. Results had showed that SVMs have the highest performance in terms of accuracy, specificity and precision. However, RFs had the highest probability in correctly classifying tumor.

The accuracy was 97.90% in WDBC when using feature selection technique (Pearson Correlation Coefficient) and Naive Bayes, Logistic Regression, Decision Tree classifier [9]. In this 70% of overall data was used training and the remainder was used for testing the accuracy of classification technique. The simulation result owe support to Logistic Regression with the minimum time taken to build the model is 0.14 seconds.

According to [10], deleterious lumps in an early stage may raise the number of cancer healing patients. The specialists had confirmed that prior detection of cancer can be a great attainment for medical science. In this model the false positive rates were very little. There were some conflicts about the accuracy of the screening.

In this research work, an ensemble method is proposed that relies on voting mechanism for result rather than depending on single classifier. Multiple feature selection techniques find the repetition of features from the individual ones to select final feature sets.

III. Methodology

The main purpose of this study is to design an ensemble method that can detect cancer efficiently. In the process, cancer dataset is given as input. Feature selection techniques are used to select the most influential features with the help of set union operation. Sequentially, classification algorithms are the evaluation process for the precise dataset. It is to be noted that both cross validation and train-test split are chosen for the purpose of comparing the outcomes. In the end, the results are voted using majority voting to achieve the final outcome. The flow chart of the whole model is depicted in figure 1.

For the greater purpose of this research the whole work shown in the flow chart of figure 1 is divided into three phases. The phases are denoted as phase 1, 2, and 3.

A. Phase 1

In this phase the most important features of the three cancer datasets are selected. All the features that are selected using PCA, PCC, and Chi2, are minimized after performing set theorem operation to obtain the most common and influential ones.

Feature selection is primarily an essential process in data mining. Feature selection is a process which explains attribute selection, variable selection and variable subset selection. It is the procedure of choosing a subset of relevant features (variables, predictors) for use in model assembly. A feature selection algorithm defines the combination of a technique of search in reason of proposing new feature subsets. It includes an evaluation measure that make a score of the different feature subsets [11]. The final feature sets are gained using set theorem. To be precise, union operation is performed to get the common features from the feature sets that are found from individual feature selection techniques. After performing this operation, only the common features from the cancer datasets are gained, and eliminated feature sets are considered to be not so influential as they are not common in all the feature sets after performing individual feature selection methods. A brief idea of the feature selection techniques that have been used in this research work, is given is this section.

1) Principle Components Analysis(PCA): For the purpose of discovering the decoration of data that is of high dimension, PCA is a very handy method. [12]. It basically highlights the similarities and the dissimilarities among the data. Larger number of variables are shrink to a smaller number, which have all the necessary information required. This process turns the larger number of interconnected variables into a few variables that are not interconnected. All of the variables are bound to the variability in the data for every remaining variable. It is to be noted that this process only performs for square matrices.

$$\omega_1 = argmax\sum_{i=1}^{n}(t_1)^2 = argmax\sum_{i=1}^{n}(X_1.\omega)^2 \qquad (1)$$

2) Pearson Correlation Coefficient(PCC): Pearson Correlation Coefficient also known as PCC is a feature selection procedure which is used to measure the strength of a linear connection between two variables. The range of the returned value by the formula is -1 to 1, where 1 mentions a strong positive connection and -1 mentions a strong negative connection [13]. The returned value of zero mentions, there is no relationship at all.

$$R = \frac{n\sum xy - \sum x \sum y}{\sqrt{(n\sum x^2) - (\sum x)^2 (n\sum y^2) - (\sum y)^2}} \qquad (2)$$

3) Chi Squared(Chi2): The Chi-Square test of independence is a statistical test to determine if there is a significant relationship between two categorical variables [14]. The Chi-Square test is used to find which variables have an association with the Survived variable. The Chi-Square statistic will also test whether there is a significant difference in the observed vs the expected frequencies of both variables.

$$X^2 = \frac{N(AN - MP)^2}{PM(N-P)(N-M)} \qquad (3)$$

To get the final feature set, we have used three kinds of feature selection methods and have done set union operation on the basis of intersecting the selected features. We have minimized the size of the feature set and it has guided to a simple and faster cancer detection classification model. Let's assume we get feature set F_1, F_2, and F_3 from PCA, PCC, and Chi2 feature selection approach. Then the primary feature sets that have come from extracting the feature between F_1, F_2 and F_3 and then combined to evaluate the feature set to get the most common feature set F. This process is as follows:

$$F = (F_1 \cap F_2) \cup (F_2 \cap F_3) \cup (F_3 \cap F_1) \tag{4}$$

The idea of doing union operation on the results of three kinds of feature selection methods is easy and it also avoids complexity.

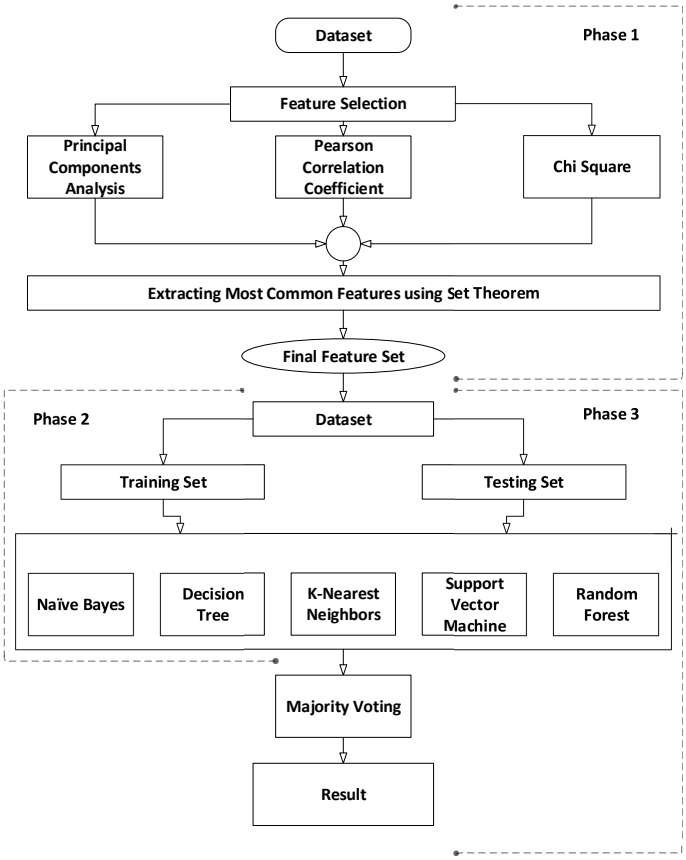

Fig. 1. Methodology

B. Phase 2

The model is trained in this phase. NB, DT, KNN, SVM, and DT classifiers are used to train the model. In this context, the cancer datasets are cross validated and train-test split for the values of cross validation k=5 and 3 and train and test split ratio of 80% and 70%.

Classifiers that play the most important role in this research work are described in this phase. A generalized knowledge of the classifiers are summarized in this part.

1) Naive Bayes(NB): Naive Bayes is one of the most effective, simple, fast and probabilistic based machine learning classifier. The classifier makes classifications using the Maximum Posteriori decision rule. A simple Bayesian network can represent it. It is popular for text classification. The Classifier is also popular for the solution for problems such as spam detection [15].

$$Posterior = \frac{Prior \times Likelihood}{Evidence} \tag{5}$$

Naive Bayes needs less training data. The classifier is highly scalable.

2) Decision Tree(DT): Decision Tree is a simple and widely used non-parametric supervised learning method for both classification and regression tasks [16]. A straightforward idea is applied to solve the classification problem. In this classifier the data is continuously split according to a certain parameter. In our problem we used two types of decision tree classifier: ID3 and J48.ID3 or Iterative Dichotomiser 3 builds decision tree by using a top-down, greedy search through the given sets of training data to test each attribute at every node [17].

3) K-Nearest Neighbors(KNN): K Nearest Neighbors (KNN) is an algorithm that keeps all available cases and classifies new cases based on a similarity action [18]. In both classification and regression predictive problems KNN can be used for solution. The boundary becomes smoother with different value of K. The training error rate and the validation error rate are two parameters to access on different K-value. KNN is very much helpful in the field of classification techniques because of: robust to noisy training data, effective if the training data is large, it has large search problem to find nearest neighbors, it also need storage of data, computation cost is high of KNN.

4) Support Vector Machine(SVM): A Support Vector Machine (SVM) is a discriminative classifier [19]. Decision planes that define decision boundaries, is the basic concept of this classifier. A separating hyperplane describes this classifier. For supervised learning, an optimal hyperplane is returned by this algorithm which categorizes new examples. A line dividing a plane in two parts by a line is the hyperplane in two dimensional space where in each class lays in either side. Both regression and classification tasks are supported and multiple continuous and categorical variables can be handled by this classifier. A dummy variable is created with case values as either 0 or 1 for categorical variables. This classifier has a regularization parameter which can avoid over-fitting. The kernel trick is used by it. Kernel models can be quite sensitive to over-fitting the model selection criterion.

5) Random Forest(RF): Random Forest Classifier is an ensemble algorithm. A set of decision trees are created by random forest classifier from randomly selected subset of training set [20]. The votes from different decision trees are summed by it to determine the final class of the test object. From any decision tree, weight concept can be applied for considering the impact of result. Tree with low error rate are

given high weight value and vice versa. The decision impact of trees would be increased with low error rate. Total number of trees to be generated and decision tree related parameters like minimum split, split criteria are the basic parameters of this classifier.

These different classification algorithms are used to get the test accuracy of the datasets. At first the model is trained with 80% and 70% of the data, and then tested with the left data accordingly. Secondly, the model is trained with 10 and 5 folds. Each time the model is tested with the remaining data in the combination.

C. Phase 3

The final and the resulting process is this phase. After training in the previous phase, the model is tested, given the test data. The results are then voted by majority voting to obtain the final outcome.

The majority voting [21] is one of the simplest and most instinctive ensemble compound techniques.

If a prediction is made by a model for each test case and final output prediction is that one which collects more than half of the votes then it is called majority voting. The ensemble method could not make a stable prediction if no predictions get more than half of the votes. In general, the majority vote classifier is defined as a series of votes. In other word, a classification of an unlabeled instance is applied on a class that gets the maximum number of votes.

Majority voting is used to achieve the final result. To get the final result, each, and every accuracy is passed through voting which decides the final output based on majority, and the accuracy gained through this process is considered to be the decided result coming at the end of the all simulation processes.

IV. Result Analysis

For this research purpose three datasets have been used. The datasets are known as Wisconsin Breast Cancer(Original) Dataset [22], Wisconsin Breast Cancer(Diagnostic) Dataset [23], and Wisconsin Lung Cancer Dataset [24]. All of the mentioned datasets are obtained from UCI Machine Learning Repository.

A. Wisconsin Breast Cancer(Original) Dataset

Wisconsin Breast Cancer(Original) Dataset consists of 699 instances having 10 attributes. There are two classes named Benign and Malignant. The class distribution of this dataset is 458(65.5%) for Benign and 241(34.5%) for Malignant.

1) Wisconsin Breast Cancer(Diagnostic) Dataset: Wisconsin Breast Cancer(Diagnostic) Dataset consists of 569 instances having 32 attributes. There are two classes named Benign and Malignant. The class distribution of this dataset is 357(62.7%) for Benign and 212(37.26%) for Malignant.

2) Wisconsin Lung Cancer Dataset: Wisconsin Lung Cancer Dataset consists of 32 instances having 57 attributes. Attribute 1 is the class label, All predictive attributes are nominal, taking on integer values 0-3. The class distribution of this dataset is 9, 13, and 10.

Here, The simulation results of our An Efficient Ensemble Method for Cancer Detection model, abbreviated as AEEMCD are demonstrated, and a comparison is drawn according to the obtained results. The results achieved from the cancer detection system under study are mounted side by side using table to give a clear view of the classifier performance differences. Results shown here are categorized according to datasets. Tables given in this section are spread over Wisconsin Breast Cancer(Original), Wisconsin Breast Cancer(Diagnostic), and Wisconsin Lung Cancer datasets respectively, Accordingly final feature sets are: 1-8, 1-11, and 1-21

TABLE I
Simulation Result for Train Test Split on Wisconsin Breast Cancer(Original) Dataset

Model	Split	Accuracy	KS	RMSE	Precision	Recall	F-Measure
NB	80-20	0.792857	0.4627	0.3519	0.905	0.904	0.904

	70-30	0.952381	0.8707	0.2182	0.953	0.952	0.951

The performance measurement of different classifiers simulated on Wisconsin Breast Cancer (Original) dataset are embedded in Table I. In this simulation Random Forrest performs best in all categories and Naïve Bayes performs worst in accuracy and Kappa Statistics. We found RMSE the least in Random Forrest (80-20) simulation. The best accuracy we found after simulation is 0.967 by Random Forrest (70-30) model. The accuracy of our proposed model AEEMCD performs best in (70-30) simulation which is 0.951 and in (80-20) simulation gives only 0.870.

	5	0.971388	0.9254	0.1692	0.971	0.971	0.971

In table II we have cross validated the dataset, clarifies the performances of different classifiers simulated on Wisconsin Breast (original) Cancer dataset. In this simulation the accuracy is between 0.835 and 0.974. We have found RMSE the least in Decision Tree (ID3) 10 fold simulation. The best accuracy we have found after simulation is 0.974 by Random Forrest 5 fold simulation. Our proposed model AEEMCD performs best in 5 fold simulation which is 0.971 and in 10 fold simulation gives 0.967 which is almost similar. Our Proposed model also gives the highest kappa statistics which is 0.952. From the previous two tables, we have come to a decision that Random Forrest classifier works best on Wisconsin Breast Cancer (Original) dataset.

	5	0.468750	0.1893	0.5865	0.465	0.469	0.6459
AEEMCD	10	0.531250	0.2910	0.5590	0.524	0.531	0.527
	5	0.531250	0.2982	0.5590	0.514	0.531	0.518

In table VI where we have cross validated the dataset, clarifies the performances of different classifiers simulated on Wisconsin Lung Cancer dataset. In this simulation all of the data also appear to be scrambled but not alike the previous one. Best accuracy is given by Naïve Bayes classifier and worst accuracy is given by Decision Tree (J48) Classifier. The accuracy of our proposed model AEEMCD performs best in both simulation which is 0.531.

From the previous two tables, it can be seen that the resulting accuracy from the tables are not satisfactory. We need to work more on this dataset.

V. Conclusion And Future Work

From table I, and II, it is obvious that the maximum accuracy is obtained by Random Forrest considering Wisconsin Breast Cancer (Original) Dataset. As per table III, and IV, we can notice that the maximum accuracy is achieved by Support Vector Machine considering Wisconsin Breast Cancer (Diagnostic) Dataset. From table V, and VI, it is visualized that the highest accuracy is obtained by K-Nearest Neighbor considering Wisconsin Lung Cancer Dataset. From above it can be concluded to a decision that, any individual classifier can perform quite better for any kind of dataset, which is not certain. For that reason, we propose a model that gives much better results than average. To analyze table I to VI, numbers show that our designed model performs better than individuals. In this experiment, we used two very common indicators which are mean of the two types of errors named Root Mean Square Error(RMSE), and Kappa statistics. Kappa statistic is utilized to calculate the classification accuracy for discriminating between the reliability of the data collected and their credibility.

The most common technique for evaluating the true accuracy of a given model is to select the most common features performing set union operation, and then apply cross validation which is based on splitting the available dataset into a training set, and a validation set and finally get the result after applying majority voting on classifiers.

The main objective of this paper is to explore the impact of the most common features of the dataset into the result by reducing the features applying set union operation in the proposed hybrid feature selection method. We have also used majority voting to find the most perfect result from the classifier. The false positive rate (FP) of the proposed model is 2.11% with a true positive rate (TP) of 97.89%. This model focuses on the misuse detection only, so there is a great scope for further research. For future work, we would like to use a great quantity of classifiers, as we should try to minimize the complexity of the classification model. Again simulation results for Wisconsin Lung Cancer dataset are not so satisfactory. That would be a place where we are very interested to work on.

***Abstract*—Concept drift in big data mining is an absolute, highly demanding research issue in this digital era. A concept in "concept drift" involved in the field of data mining (DM) and machine learning (ML) studies is referred to the relationship between input features and class variables. In real-life classification problems, a concept can be changed or new concepts may appear over the time. Innumerable data mining classification models, new methods are propounded every day to enhance the solution to this raised issue. In this paper, we have extended our vision to attempt an investigation in resolving the issue of concept drift detection, and carried out analysis for creating a better method to adapt to the newly arriving concepts. We have addressed the issue of concept drifting for mining big data, and presented an evolutionary, concept-adaptive, rule-based approach that classifies novel class instances in "concept drifting". The proposed method clusters the big data and extracts decision rules from each cluster for classifying instances with existing classes. For classifying new unlabelled instances, the proposed method first examines and ensures if the new instances belong to the clusters in existence or not. If the new instance does not appear to belong to the existing clusters, we have considered this instance as a novel class instance. Then, we have extracted new classification rules from the new instances data and added these new rules with existing rules. Performance evaluation tests of the proposed method have been conducted using a number of datasets provided by UCI (University of California, Irvine) machine learning repository. The calculated result proves proposed approach as an effective and efficient means of detecting novel class, which implies concept drift identification at the same time.**

Keywords*—Concept Drift; Big Data; Data Mining; Machine Learning; Novel Class Instance;

I. Introduction

Big Data analysis becomes an attractive research area in ML(machine learning) and DM(data mining) at present time [1], [2], [3]. Detection of concept drift in streaming big data captured so much attention of intelligence computational researchers [4], [5]. In big data a large volume of new data generated continuously with time that cannot be restricted to any pre-defined order [6]. Big data are not always accurately stationary. A new data, in a non-stationary environment, could have different knowledge pattern and can probably change the data distribution and makes the current prediction model unsuitable. This circumstance is recognized as concept drift [7]. Concept drift occurs due to difference in the assignment of data in disparate time phases or change the pattern enciphers [8], [9]. Generally, big data should have the following four properties: (1) volume, (2) variety, (3) velocity, and (4) veracity. Volume refers to the amount of generated and stored data. Variety refers to the number of types and nature of data. Velocity is at which pace the data is being processed. Veracity is the quality of data that affects the accurate analysis.

The inauguration of big data applications with huge volumes of high-dimensional instances, often become accessible in stream mode, and impose major obstacles to all learning tasks, among which classification is significant. [10]. On account of numerous reasons, where absent features or acquisition failures are included, the data vectors that are available might often have missing entries, which due to improper treatment, can result in classification. High-dimensional data normally exhibit recognizable patterns that can be leveraged to effectively embed them into low-dimensional spaces. Classification is the function of learning such embedding maps from a finite number of training data with their correct class labels. Big Data applications are rising high and being researched by the region of computer science, in which applications require distributed and present classification function and pattern recognition of huge data sets accordingly which are collected from many different sensor networks, medical data, online form registrations, video and imaging systems, etc. In our paper, we have proposed a new approach for big data mining in the presence of concept drift. Our proposed approach applies clustering technique with adaptive rule-based classifier to classify the unlabelled instances in big data and also predict the novel class instances in big data. The suggested method clusters the big data initially and then extracts classification rules from each of the cluster. To classify new unlabelled instances, it checks if the instances belong to the existing clusters or not. If the new instance does not belong to any of the existing clusters, it indicates that concept drift happened. Afterwards, it extracted new classification rules from the new instances and added these new rules with existing rules. We have assessed the execution of propound formula on conventional datasets from University of California, Irvine (UCI) machine learning repository [11] and the results that are originated from experiments proved the methodology we suggested as effective and efficient in classifying data with identifying novel class instances in data.

The remaining portions of this manuscript is designed as Section II elaborately examines the related works. Section III propounds the proposed method. Section IV reviews the experiment results. Finally, Section V explores the conclusions and future work plans.

II. Related Work

In 2017, Liu et al. [12] proposed a concept drift detection method on the basis of subspace learning that mostly depends on angle optimized global embedding (AOGE) and principal component analysis (PCA). AOGE and PCA algorithms analyze the projection angle and the projection variance for concept drift identification. With observation, the change of objective functions for data streams, concept drift is distinguished. If concept drift is present, it is re-organized, based upon subspace learning which utilizes the new data stream patch. After that, the data streams are processed with dimension reduction for classification procedure. Lu et al. [13] proposed a chunk-based incremental learning method called Dynamic Weighted Majority for Imbalanced Learning (DWMIL), which analyzes concept drift in data streams and class imbalance problem. DWMIL avails an ensemble framework that assigns the weight of the base classifiers dynamically with respect to their performance on current data chunk. DWMIL is an incremental learning model and achieves high performance by keeping limited number of classifiers. In 2016, Haque et al. [14] proposed an active (semi-supervised) framework to classify data streams. It can detect concept drift and ensures chunk limit in a robust way by identifying crucial changes in classifier confidence. Additionally, it utilizes confidence scores to acutely choose specified number of data instances that arrives from the newest chunk as flags to update the classifiers later. They hypothesized the use of confidence estimators and the impact of concept drift on classifier confidence.

In 2015, Yang and Fong [15] used three representative singletree induction algorithms (VFDT, ADWIN, iOVFDT) to explore the occurrence of concept drift. iOVFDT balances accuracy, tree size, and learning speed with a compact size of model and less usage of memory. The results conclude that ioVFDT displayed better performance compared to the other two aforementioned algorithms, due to its adaptive tie threshold, making it suitable for both artificial and real world concept drift data streams. In 2015, Ortiz et al. [16] created an approach named Fast Adapting Ensemble (FAE), which is an ensemble method designed to adapt to concept drifts rapidly and specifically deals with recurring concepts with expertise. FAE harbors a set of inactive base classifiers that change their state to being active within a very short span as the concept they represent re-emerges. FAE uses a drift detector (this helps to process the abrupt concept drifts) to conclude when to construct and include a new base classifier. FAE also uses a weighted majority vote to acquire the global ensemble decision and establishes a formula for adjusting the base classifiers weights, which permits the algorithm to expand or reduce the weights according to their performances. Krawczyk, and Woźniak [17] proposed a novel modification of weighted one-class support vector machine transformed to the relentless streaming data analysis. Their hypothesis prioritized the improved alterations of weights used by WOSVM. They implemented the incremental training of weights, which was followed by forgetting mechanism. They finalized with the theory that the efficient one-class classification model for data streams along with concept drift would be reprized from combination of incremental learning assigned with highest weights to object that arrive from new data chunk with forgetting by sigmoid based function.

In 2015, Wang and Abraham [18] concentrated on concept drift detection that affects binary classification models and demonstrates a framework (Linear Four Rates, LFR), which can identify the concept drift and distinguishes the updated data points of the new concept. The wide-range vision of LFR makes it possible to function for both batch and stream datasets, which are imbalanced datasets. It can also use user-specified parameters that are automatically easy to understand, different from other methods of detecting concept drift. LFR stands out with better performance than the existing popular approaches in respect of early concept drift detection, low false alarm rate and high detection rate across the various sorts of concept drifts. Mirza et al. [19] presented an Ensemble of Subset Online Sequential Learning Machine (ESOS-ELM) to learn from class imbalanced data that occurs from drifting data streams. ESOS-ELM is an ensemble approach for classification in imbalanced environment. It's also an ELM-Store module, which harbours information of old concepts and a change detector that can instantly detect concept drifts. In ESOS-ELM, the ensemble is processed with the equitable subsets of streaming data. In 2015, Kanoun and Schaar [20] addressed the limitations of streaming big data by suggesting an online energy-efficient scheduler that can promptly learn the environmental changes by reinforcement learning techniques to increase the QoS (i.e. throughput and output quality) even with restrictions for resource use. They identified the scheduling problem as a Stochastic Shortest Path problem (SSP) and introduced a learning algorithm that reinforces itself to adapt to environmental changes and resolve this barrier even with recurrence of concept drift. L. Rutkowski et al. (2015) [21] proffered a new criteria that apply the theory of splitting nodes of decision trees for classifying data streams. The nodes are split according to the count of impurity, otherwise addressed popularly as misclassification error. The proposed measure or criteria observes if the selected ideal one among all the resident properties of current series of elements in node is equally the best in the entire stream or not. Also, this criterion in question was blended along with the criterion developed from Gini index. The synthesized algorithm reproduced quite efficient results while processing data streams in different environments.

In 2013, Farid et al. [22] introduced an adaptive ensemble learning classifier to handle deficiencies that particularize concept drift, infinitesimal length, minimal labeled data, and concept evolution for detecting novel class in data streams with concept drifting. The suggested model frequently upgrades itself with freshly arrived data points to keep up with most up-to-date concepts in data stream. The majority of weighted predictions among the classifiers in model classifies unlabeled observations. The model, M, labels the instances present in each sub-stream and a new classifier are adapted with the most contemporary dataset.

III. Big Data Mining with Concept Drifting

A. Concept Drift

Big Data is a vast source of instances that appear in an organized order. So, it enforces certain restraints on the learning system, which are unable in accomplishing the destined result with the help of the orthodox algorithms from this realm. Suppose, a stream of data made up of some states which are grouped, $G = \{G_1, G_2, \cdots, G_n\}$, where G_i is originated by a

diffusion D_i. If we consider streaming data which is stationary where the order of instances are symbolized as $D_j = D_{j+1}$, the transition can be marked as $G_j \rightarrow G_{j+1}$. Meanwhile, the behaviour of data may change in time due to many reasons in our modern and realistic problems. This event is addressed as concept drift. The fundamental problem is the alteration in the input and output(I/O) with time. A "drift" or change from a standard concept occurs because of the "subtle changes" in attribute values of big data. Concept drift possibly appears where data is collected over time, with or without predictions on supervised learning problems. Typically, these are known as online learning problems, where change is expected in the data with time. Concept drift is basically bifurcated into (1) real concept drift, and (2) virtual concept drift. The type of concept drift that can alter the decision boundaries also known as posterior probabilities and can also have an effect on unconditional probability density function is called real concept drift which imposes a threat on learning system. Another type of concept drift is virtual that does not affect the decision boundaries, but transform conditional probability density functions, thus it cannot overpower the recently used learning methods. But, it is mandatory for us to identify concept drift. The four prior applications that are popularly used to deal with concept drift are: concept drift detectors, online learners, sliding windows, and ensemble learners. We might need different concept drift detection and handling procedures depending on different situations. Several ways to handle concept drift are: periodically update, detect and choose model, learn the change, weight data, and data preparation.

B. Proposed Approach

If concept drift is existent in big data, classifying it will be quite an arduous task. Because, machine learning models are trained on fix number of class labels and learning models misclassify the novel class instance as existing classes in classification process. It's very common in real-life classification problem that observations with latest class may manifest itself over the time. A rule-based learning model has been propounded to classify large data with clustering technique that can classify unknown instances and detect novel class instances. The proposed method divides the big data into small sub-datasets, so that each of the sub-data can fit into the computer memory and easy to manage. Then we cluster the each sub-data into several clusters. Data clustering is an approach of segmenting data observations that are similar to each other [23]. Then classification rules are extracted from clusters using decision tree (C4.5) algorithm [24], as extracting classification rules from trees are very well known approach [25]. C4.5 decision tree algorithm is a top-down divide and conquer recursive process, which classify the unseen instances based on the several seen instances [26], [27]. C4.5 decision tree algorithm uses Gain Ratio to select the best splitting attribute. Generation of a classification rule from individual leaf of the decision tree. From the root to leaf defines a path that corresponds to a rule-set. The perk of extracting rules from tree is that it's easy to marge and can be executed in any order. Latest rules can be merged to previously extracted rules. Where as decision tree merging is quite complex process. For classifying new unlabelled instances, the proposed method first checks the new instances belong to the existing clusters or not. If the contemporary observations does not fit in to the existing clusters, then we have considered this observations as a novel class instance. Then, we have extracted new classification rules from the new instances and added these new rules with existing rules. Table I presents the frequently used notations and terminologies in this paper. Fig. 1 describes the proposed method for mining big data in concept drifting employing clustering with rule-based classifier, which is illustrated in algorithm 1.

TABLE I: Frequently used notations and terminologies.

Notation	Terminology
D_{Big}	Big Data
D_i	Small data that into the memory
C_j	Cluster
DT_j	Decision tree
$rule$	Classification rule
x_{New}	New data point/ instance
x_{Novel}	New instance with novel class

Algorithm 1 Big Data Mining with Concept Drift

Input: *Big Data, D_{Big}; C4.5 Classifier;*
Output: *Rule-set*; // Classification rules.
Method:

Rule-set = $\emptyset$;
divide D_{Big} into small sub-data sets $D_1, D_2, \cdots, D_N$;
for i = 1 to N **do**
  cluster D_i into several clusters $C_1, C_2, \cdots, C_M$;
  for j = 1 to M **do**
    build decision tree, $DT_j \leftarrow C_j$ using C4.5 classifier;
    if $error(DT_j) \leq 0.5$ **then**
      Rules $\leftarrow DT_j$; // extracting the rules from DT_j.
    end if
  end for
  Rule-set = *Rule-set* $\cup$ *Rules*;
end for

To classify new instance, x_{New}:

if x_{New} belongs to any C_j **then**
  classify x_{New} with existing rules;
else
  extract *Rule* $\leftarrow x_{New}$;
end if
add new rule with existing rules;

IV. Experimental Analysis

This section constitutes details of datasets, experimental setup and performances.

A. Datasets

Datasets are assembled from UCI machine learning repository [11]. Table II provides a brief interpretation of the datasets. NSL-KDD dataset is used quite frequently as a standard for assessment of concept drift detection approaches. This dataset is the updated form that has solved the shortcomings present in the KDD99 dataset. In Table III, we presented the variety instructed samples of different genre used in the NSL-KDD dataset. There are 683 data instances and 35 categorical attributes with 19 class values in the large soybean dataset. Another dataset employed in our work is image segmentation data

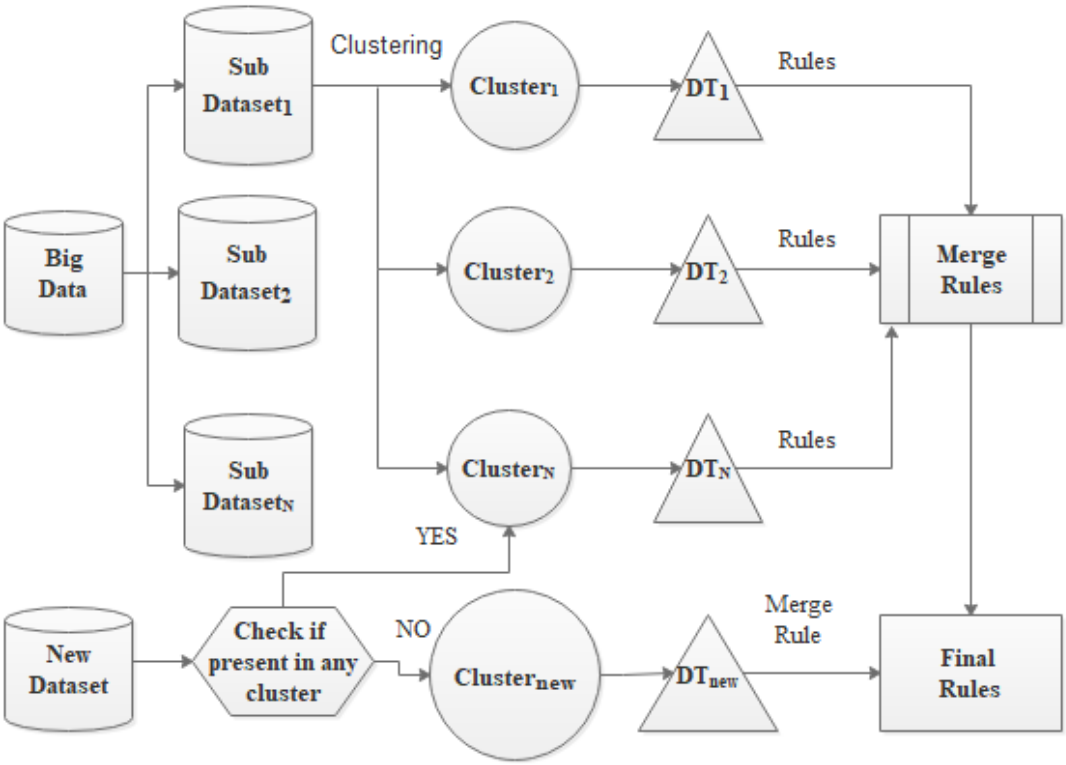

Fig. 1: Propound method for mining big data in presence of concept drift.

of 7 outdoor images, where instances were drawn randomly. Categorization with respect to each pixel was generated from handpicked images. The 3X3 region was assigned for every instances in the employed dataset. The basic target for using this specific dataset is accomplishing a factual reasoning for image segmentation research. This database has 19 features and 7 categories and 2310 data instances.

TABLE II: Dataset details.

Dataset Name	Features	Category	Observation	Target
NSL-KDD	41	Real & Categorical	25192	23
Soybean-Dataset	35	Categorical	683	19
Segment-Test	19	Numeric	2310	7

TABLE III: The NSL-KDD dataset.

Category	Target	Observation
Normal	normal	13449
Denial_of_Service (DoS)	neptune, land, back tenddrop, smurf, pod	9234
Remote_to_User (R_2_U)	warezmaster, guess_passwd, impa, spy, ftp_write, warezclient, multihop, phf	209
User_to_Root (U_2_R)	rootkit, buffe_overflow, loadmodule, perl	11
Probing	protsweep, nmap ipsweep, satan	2289
	Total = 23	Total = 25192

B. Experimental Setup

We have enacted the proposed hypothesis in Java using NetBeans IDE 8.2. NetBeans is an open-source integrated development environment that gives assistance to the development for all types of Java application. The code for decision tree (C4.5) is adopted from Weka 3.8, which is a data mining software in Java [28].

C. Experimental Results

Tables IV to VI describe how the presence of novel classes have an impact on the performance of the datasets that we have used. The outcomes represent that our proposed method, which is taught with a stable amount of sets, displays satisfactory fitness in learning and classifying new concepts, and overshadows the conventional C4.5 decision tree induction algorithm. Table VII shows the summary of some useful metrics of success of prediction when the classes are very imbalanced. It presented the values of the metrics called Precision, Recall and F-score respectively on each of the datasets that are shown in Eq. 1 to Eq. 3. Fig. 2 to Fig. 4 show the classification accuracy between proposed method and C4.5 classifier in the appearance in novel classes on the NSL-KDD, Soybean, Segment-test datasets respectively.

$$Precision = \frac{TP}{TP + FP} \tag{1}$$

$$Recall = \frac{TP}{TP + FN} \tag{2}$$

$$F - score = \frac{2 \times precision \times recall}{precision + recall} \tag{3}$$

TABLE IV: Performance of propounded method in the novel class manifestation using the NSL-KDD dataset.

Training Observations	Testing Observations	Enduring Classes	Novel Classes	Accuracy
13449	9234	1	6	85.68 %

V. Conclusions & Future Work

In this paper, we successfully attempted in introducing a standard approach for mining big data in the presence of concept drift employing clustering with rule-based classifier. A major problem of dealing with big data is managing and storing it into machine's computer memory. The most popular technique is the partitioning of big data into small sub-datasets, so that each sub-data can easily be alloted to the memory of a computer. The proposed system clusters each of the sub-datasets to group the instances that are similar to each other. We then extracted classification rules from each cluster using decision tree induction technique. Merging decision trees or any other learning classifiers is a quite difficult task, whereas merging rules are quite easy owing to the fact that rules do not require any definite order of execution. We can add new rules to previously extant rules in our system without disrupting them. To find the concept drifting in data we have considered clustering technique. If any new data point does not belong to any clusters existing in our learning method, we have considered this instance as a novel class instance. Novel class instances come with new class labels in the data, generally in streaming data environment. Our conducted experiments demonstrated the performance of the proposed approach as efficacious in manner of generating better and accurate results with minimized error. We plan on extending our work in future under dynamic feature environment.

Abstract— **In recent years managing Big Data is a big challenge. Big data has huge volume, variety of format and its volume increases at a very high velocity. Traditional data structures fail to handle these types of data. Moreover Big Data storage scheme is very expensive. So some efficient scheme is needed. In this paper we show the application of dynamic Extendible Array for Big data storage. It is an efficient scheme which has better performance over other approaches. We used Map Reduce concept to distribute the data in heterogeneous environment. The data that belongs to different dimensions are distributed to different machines to do the operations efficiently. The basic operations including insertion, deletion, update and retrieval of various types namely point key query, single key query and range key query are performed. Moreover the dynamic extension of the structure without reorganizing the existing data is performed. Experimental results are well studied. We used cheap commodity machines for our implementation.**

Keywords—MapReduce, Extendible Array, Dynamic Array storage, Big Data Storage, Future data maintanance.

I. INTRODUCTION

The large volume with diverse dimensionality attribute of arrays make it popular in various researches, like medical imaging, geographic information system, environmental and astronomical surveillances, or high precision prototypes of physical consequence [1][2]. These applications force an array to demand a scalable system for array operations. But the Traditional Multidimensional Array (TMA) does not provide dynamic scalability as it requires reorganization of the previous data in case of a new data set entry. Hence, the TMA structure is unable to fulfill the dynamic data velocity of Big Data. Much IT investments are going towards managing, maintaining and analyzing big data. Sometimes big data is represented by three Vs. - Velocity, Variety and Volume [3]. Big data comes with some big problems. One of them is big data storage. Huge data Volume which is increasing with high Velocity (termed as future data) with Variety in format can't be handled using tradition storage systems. Sometimes big data is unstructured. So storing huge amount of unstructured data in relational database is not a very good idea. Moreover analysis of huge amount of data is time consuming in relational database systems. So some efficient and dynamic data storage techniques should be adopted which will speed-up storing and analyzing of big data especially future data.

In this paper, we propose a big data storage system using commodity machines in heterogeneous environment. The scheme employs a distributed storage model using extendible multidimensional arrays[2][9][15]. For storing high dimension data arrays are used extensively[3][11]. This paper presents a dynamic array storage namely Extendible Karnough Array[2][12][16] based map reduce storage technique. The EKA is a dynamic array system that can store the future data. In this paper we proposed map reduce algorithm for fast retrieval of array elements in distributed environment for future data maintenance. Map Reduce is now mostly used for distributed analysis system. Map reduce algorithms are used extensively for example, Google implements the map reduce paradigm internally for the last decade and jobs of one hundred thousand are executed per day on Google's clusters which is nearly twenty petabytes of data per day. Map Reduce offers scalability, distributed analysis and reliability which are crying need for an efficient big data storage system [3][17].

II. RELATED WORKS

Some of the dynamic array models are summarized in this section. [16] employs an extendible array that extends the array boundary dynamically. It on ly treats the history tables in an efficient way. The extendible array model presented in [21] introduces axis vectors that stores necessary information like the auxiliary tables.[4][5] mentions the Extended Karnaugh Map Representation (EKMR) model that signifies an n dimensional data by a set of two dimensional arrays. But EKMR is also not dynamically extendible. The Extendible Array (EA) model [6]-[12] can meet the expended data velocity by solving the limitation of a TMA using dynamic memory allocation during run time as form of subarrays. [9] represents an EA based model which can convert the n dimensions of an array by only 2 dimension. The subarrays of EA based models are n-1 dimensional and hence it can utilize better storage compared to TMA. However, the EA based models cannot meet the expected huge storage requirements like Big Data applications as they cause address space overflow. [10] represents an EA model based on [9] which can delay the address space overflow and can meet the expected storage requirements of large volume applications efficiently compared to other EA models. [2]. [11][12] represents another EA solutions to address space overflow based on EKMR. None of

the above model used either the idea map reduce retrieval or distributed array storage. We implemented distributed array storage and applied ma preduce technique for retrieval. The map reduce architecture is a way to originate and activate large data sets that enlarges the scalability of parallel applications efficiently which attains high performance [13]. [14] improves [13] named Map-Reduce-Merge which introduce the Map-Reduce with a Merge phase that can competently combines the partitioned and sorted results of the previous map and reduce units. [15] employs Map-Reduce on Big Data applications. In this paper, we have used the Map Reduce architecture to utilize the data sets of an EKA based model. The introduction of map reduce model in dynamic arrays is employed in this paper to speed up the data retrieval and increase the storage capacity.

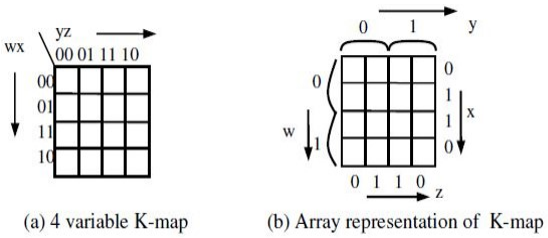
III. THE EXTENDIBLE KARNOUGH ARRAY (EKA)

The EKA is illustrated in this section. The details can be found in [2][12]. The idea of date distribution is possible by EKA because the dimensions and subarrays introduced in EKA are completely independent to each other. Hence the subarrays are send to different machines and merged by another machine for cumulative results.

A. Structure of an EKA

The EKA is a multidimensional Extendible Array model that utilizes the concepts of Karnaugh Map (K-map). The K-map is awell-knowndepiction employed inBoolean expression minimization typically assisted by mapping values for eachpotential combinations.Fig. 1 (a) depicts a 4 variable K-map representation of a Boolean function (2^4 combinations). The row is denoted bythe pair (w, x) and the column is denoted bythe pair variables (y, z). The row and the column indicate the potential combinations of a Boolean function in a form of two dimensional array.

Adjacent Dimension. The row pair and column pair of a K-map are re-expressed as row dimension and column dimension respectively of an EKA. Here, the indices of the row dimension are adjacent to each other and the indices of the column dimension are adjacent to each other. The adjacent dimensions of row is denoted as $adj(z) = y$ or $adj(y) = z$ and adjacent dimensions of column is denoted as $adj(w) = x$ or $adj(x) = w$ and.The EKA representation of Fig. 1(a) is shown in Fig. 1(b).



Auxiliary Table. The EKA model requires some auxiliary tables for managing scalability of its structure and also for managing faster data retrieval from the structure as follows:

- *History Table* which is required monitoring extension information.
- *Co-efficient Table* which is required for storing the co-efficients of addressing function. The addressing function can be defined as follows:

$$f(x_n, x_{n-1}, x_{n-2},\ldots,x_2, x_1) = l_1l_2\ldots l_{n-1}x_n + l_1l_2l_3\ldots l_{n-2}x_{n-1} + \ldots + l_1x_2 + x_1. \quad (1)$$

where, $< l_1l_2\ldots l_{n-1}, l_1l_2l_3\ldots l_{n-2}, \ldots, l_1>$ are theco-efficients of addressing function and l_i indicates the length of dimension d_i.

- *Address Table* which is required for monitoring the extended subarays of an EKA.As the subarrays of EKA are divided into segments, hence this table will store the first address of each segments by storing first address.

(a) 4 variable K-map (b) Array representation of K-map

Figure 1: Realization of an EKA Using K-map

B. Operations on EKA

Extending Dimension. Consider the array in Fig. 2(a), the dimensions are d_1, d_2, d_3 and d_4 and thesize of the array is [l_1, l_2, l_3, l_4] andsubscripts varies from 0 to l_i-1. In the current example $l_i = 2$. The dimension (d_1,d_3) and (d_2,d_4) are adjacent dimensions respectively. The extension of $d_1$that can be done logically isshown in Fig. 2(b). The extension is done by allocating subarrays and is determined by [l_2, l_3, l_4] (i.e. 3 other dimensions). The number of segments is thelength of the adjacent dimension, $adj(d_1) = d_3$; In this case it is $l_3 = 2$. The size ofeach segmented subarray extended along dimension d_1 is determined by [l_2, l_4]. Afterextending along dimension d_1, the length of that dimension is incremented by 1. Foreach extension the corresponding auxiliary tables are maintained accordingly. Fig.2(c), 2(d) and 2(e) shows the extension realization along dimension d_2, d_3 and $d_4$respectively.

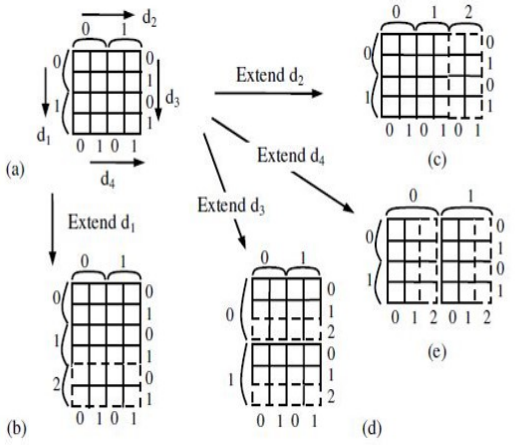


Figure 2: Logical extension of a 4-dimensional EKA.

The EKA(4) shown in Fig.3 is taken as an example in this section. This EKA(4) is going to be extended for the corresponding 4 dimensions. The initial situation is shown in Figure 3(a). The value of history counter is initially 0, the address table has the first address and coefficient table is initialized to 1. During the extension of $d_1$and d_3 dimension size of the segment is $l_2 \times l_4$ which is a two dimensional array and so coefficient vector is one dimensional. Hence for our example

we use l_2 as coefficient vector for d_1 and d_3 dimensions. Similarly $l_3$is used as coefficient for $d_2$and d_4 dimensions.

Retrieval. Let the value to be retrieved is indicated by the subscript $\langle x_1, x_2, x_3, x_4\rangle$. The maximum history value among the subscripts h_{max}= max($H_{d1}[x_1]$, $H_{d2}[x_2]$, $H_{d3}[x_3]$, $H_{d4}[x_4]$) and the dimension (say d_{max}) that corresponds to history value h_{max} is determined. h_{max} is the subarray that contains the desired element. This is because;the history values are linear numbers, therefore subarray having maximum history value was constructed at last. Hence the desired element remains in the segment that makes the subarray having history value h_{max}. Now the first address and offset from the first address is to be found out. The adjacent dimension $adj(d_{max}) = d_{adj}$(say) and its subscript x_{adj} is found. Now the first address of the segment is

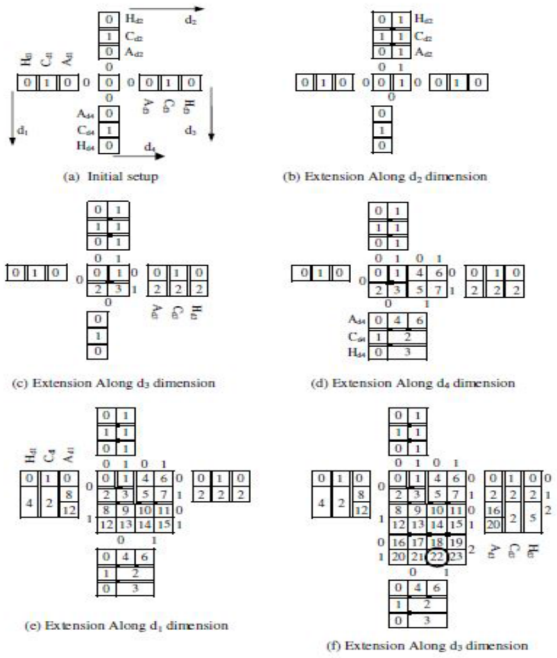

Figure 3: An Extension Realization of EKA(4)

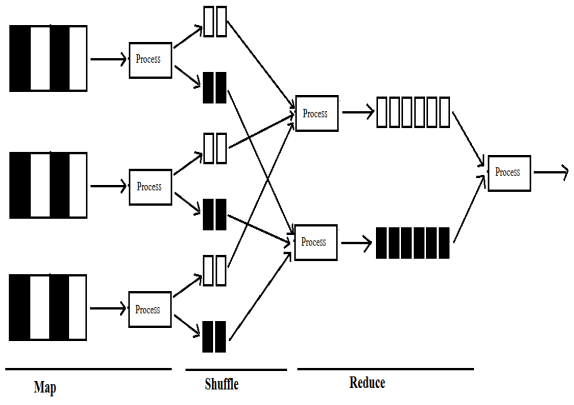

Figure 4: The MapReduce implementation model

found from$A_{dmax}[x_{max}][x_{adj}]$. The *offset* from the first address is computed using the addressing function (see Eq. 1); the coefficient vectors are stored in C_{dmax}. Then adding the *offset* with the first address, the desired array cell (x_1, x_2, x_3, x_4) is found.Let four subscripts ⟨1, 0, 2, 1⟩ for dimension d_1, d_2, d_3, and d_4 is given (see Figure 3.3(f)). Here h_{max}= max($H_{d1}[1]$, $H_{d2}[0]$, $H_{d3}[2]$, $H_{d4}[1]$)= max(4, 0, 5, 3) =5, and dimension corresponding to h_{max}i.e. d_{max} = d_3 whose subscript x_{max}= 2 and $adj(d_{max}) = adj(d_3) = d_1 = d_{adj}$*and* $x_{adj} = 1$. So the *firstAddress*=$A_{d3}[2][1]$ = 20, and offset is calculated using the coefficient vector stored in coefficient table C_{d3} which is 2. Here, *offset*=$C_{d3}[2]*x_4 + x_2 = 2*1 + 0 = 2$. Finally adding the offset with the first address the desired location 20 + 2 = 22 is found and circled in Fig.3.

IV. The Map-Reduce Model for Distributed Array Storage

The mapping phase is implemented by invocatingmachines automatically partitioning the input data into a number of splits. These splits are processed according to parallel scheme by a number of machines. The reduce phase merges the distributed partitions into the intermediate key using a partitioning function namely hash function. Fig.4 shows the overall flow of a MapReduce operation in our implementation [13].

We have used EKA[2] as basic storage structure. In its initial format has 4-dimensions. We will use this basic format and extend along the each dimension. Each of the dimensions can be used for storing specific type of data. For example dimension one and two may store string type data where dimension three and four may store integer type of data.

A. Distribution of Dimensions

The EKA has initially four dimensions. It has also internal mechanism to store and retrieve data. This internal mechanism and storage of dimensional data introduce extra overhead to single machine. This burden of single machine is distributed among many machines. In its simple form each dimension is distributed with single node machine. So for four dimensions we need four single node machines. Where internal mechanism for storing and retrieving data is maintained by the master machine. Fig.5 shows a 4D EKA. Fig. 6 shows the distribution scheme for master and slave machines.

Master Machine: Master machine performs all the initializations for single node machines. The main task of master machine is to maintained internal structure and mechanism of EKA which is complex. So master machine is responsible for storing EKA's History table, Co-efficient table and Address table. Operations are given through this machine.

The machine modify or access these auxiliary tables with respect to desire operations

Slave Machine: Slave machines are single node machines simply store the dimension data. They are responsible for storing data in their corresponding format. In response to the

master machine the single node machines simply allocate memory and retrieve data according to the type of the query.

V. Implementing Map Reduce Concept

In this section EKA we describe the implementation in heterogeneous environment. Heterogeneous environment in the sense that the single node machine may have different configurations, and most importantly they store data of different format or type. This heterogeneity is maintained and merged by implementing Map-Reduce concepts in extending dimension and data retrieving.

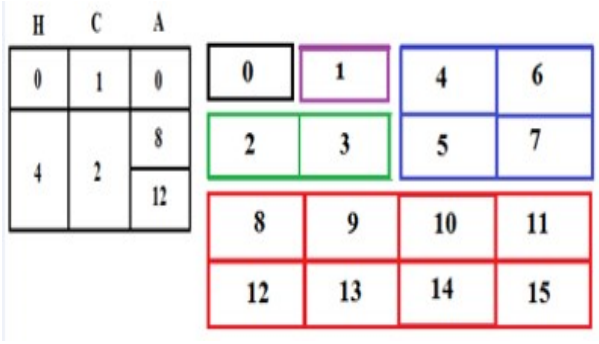

Figure 5: Main structure of EKA.

Map Reduce Concepts in Extending Dimensions

***Map-Phase*:** Extending along any dimension is done by first determining the specific node machine and then delivering the task of extension to the corresponding node.

***Reduce-Phase*:**The corresponding node performs all the tasks for extension such as memory allocation, data storing and sending feedback message to master node. Then the master node modify the auxiliary tables with respect to the feedback from the corresponding single node.

Map Reduce Concepts in Retrieving Data

Retrieving data may include communicating with all the single node machines. Master node first takes the instructions and then separates the indices that corresponds to the data in specific dimension that resides in specific single node machine. Then data is retrieved.

Map Phase: Gets instruction, separates indices and send requests to the specific single node with indices that belongs to the corresponding dimension.

Reduce Phase: Each single node machine collects the corresponding data for given indices and sends feedback to master node with retrieved data. Thenthe master node merges and show all the retrieved data. Fig. 7 shows a schematic diagram for map reduce technique for retrieval of data.

VI. Experimental Results

We measured the required time to retrieve data for different extension length along each dimension. For retrieve we accessed the middle square of the whole data space. We implemented a range query as shown in black part of the Fig. 8. For a multidimensional we implemented the different part in each dimension. For example if the length of dimension one is 20 then 5 to 15 indices will be selected for dimension one. This will help us to get average result.The experiment is repeated up to each dimension length is 60. The result is compared with single machine implementation of EKA (4).

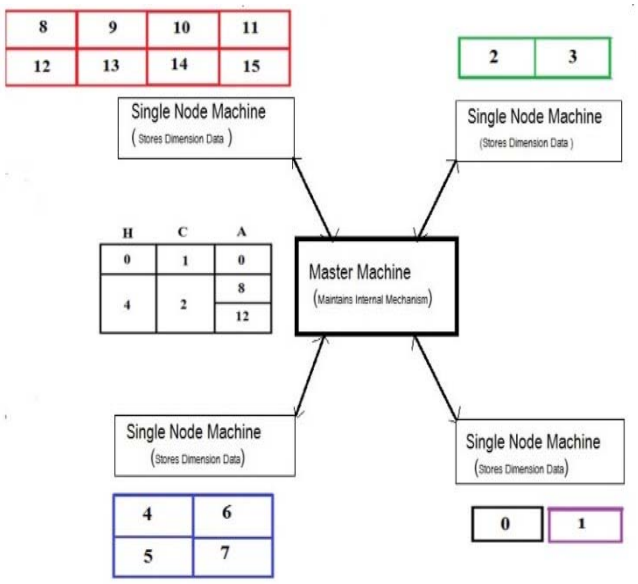

Figure 6: Distribution of dimension

We measured the required time to retrieve data for different extension length along each dimension. For retrieve we accessed the middle square of the whole data space. We implemented a range query as shown in black part of the Fig. 8. For example if the length of dimension one is 20 then 5 to 15 indices will be selected for dimension one. This will help us to get average result.The experiment is repeated up to each dimension length is 60. The result is compared with single machine implementation of EKA. The performance is shown in Fig.9. When we use multiple machines the length of dimension of the EKAis increased from 75 to 110 this means the volume of the array increases $(75)^4$ to $(110)^4$. This is huge improvement for array storage. If the average data size is 4 unit and M is the size needed to maintain the structure then

In single machine we get capacity, $c1 = (75)^4 \times 4 + M_1$

In multi machine we get capacity, $c2 = (110)^4 \times 4 + M_2$

Increased capacity = (c1/c2), which is approximately 4.63.So using multiple machine we able to increase the capacity 4.63 times larger than single machine.

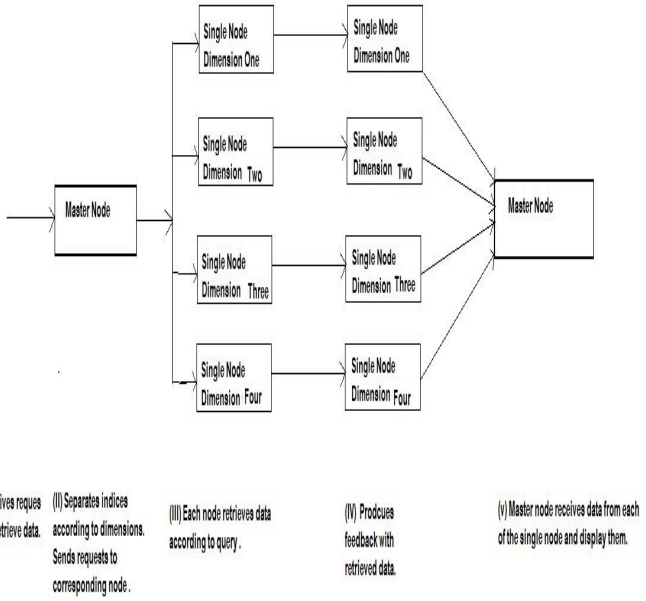

Figure 7: Map-Reduce in retrieving data

From Fig. 10 we can also see the retrieval performance is also improved for map reduce technique. This is because 4 processor will be more powerful than the single one. Figure 9 shows the improvement i.e speed up of the two schemes. The speed up is not so good because we used heterogeneous environment where the machines are connected through optical fiber and core switch for networking among them.

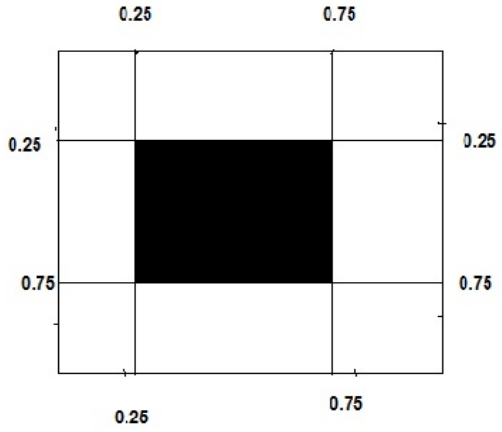

Figure 8: Map-Reduce retrieving in EKA

VII. CONCLUSION

In this paper we analyze and implement new array storage using EKA and Map Reduce concepts. Distributed technique is compared with the single machine technique. As in distributed technique many computations are done in parallel, from the analysis we can simply show that our technique is better than single machine concept. We all the dimension data and structure of EKA in main memory. We can now recommend our scheme to use it for big data storage where multiple machines are available and huge amount of data need to be stored. The scheme will be efficient in for big data storage in actual situation because the subarrays are independent to each other and makes easy to implement in parallel environment. We believe the scheme can be more effective for actual parallel environment for huge data d management especially for future data.

***Abstract*— Distributed file system (DFS) is a transformation of traditional file systems to perform file read, write and execution of petabyte or larger-sized datasets with high-velocity and different structures. In order to process these large amounts of data in an inexpensive and efficient way, Hadoop Distributed File System (HDFS) is used and designed to scale up from a single server to hundreds of servers, with a very high degree of fault tolerance. Secured and optimized distributed file system for ISP user log management is a centralized log analytics platform that supports collaboration in a distributed environment. DFS for ISP log provides a uniform name space for all ISP along with location independence and location transparency. Any user's internet access log can be accessed and analyzed using apache sparks data brick file system on stored log in DFS. In this paper, at first, limitation of popular DFS like NFS and CIFS is explored. ISP log management, DFS file architecture and security is considered for designing proposed ISP log management system. Finally, simulation on proposed distributed file system and query processing is performed to obtain the desired result related to optimization and security of the proposed distributed log analysis system.**

Keywords—Hadoop, DFS Security, NFS, ISP log, Optimize

I. INTRODUCTION

From a security point of view, the purpose of a log is to act as an alert or red flag to detect suspicious activity. Reviewing access logs could help identify malicious activities on any system. The primary objectives for log management implementations are concerns about security, system and network operations and regulatory compliance. Given the large amount of log data generated by systems, it is impractical to preserve and review all of these logs manually each day. Effectively analyzing large volumes of diverse logs can pose many challenges, such as volume, normalization, velocity and veracity. Commercial organizations may procure complete solutions or build their own log management tools, assembling the features from various open-source components, or acquire systems from commercial vendors. Log management is a complicated system and organizations often make mistakes while approaching it.

A distributed file system (DFS) is a file system with data stored on multiple servers [1]. The data is accessed and processed as if it was stored on the local client machine. The DFS makes it convenient to store and process data files of any relational databases or share files among users on a network in a controlled and authorized way [2]. The server allows the client or users to share files and store data just like they are processing the information locally.

An NFS server can mount directories that are exported by other NFS servers [3]. However, it cannot export share to its clients. NFS supports location transparency but not location independence. This is due to its decision not to enforce a common name space. This makes it harder to share files. CIFS cannot really be described as a legitimate distributed system. It merely provides a way to access resources over a network. It does not provide either location transparency or location independence. AFS does not use unix file semantics. AFS only supports directory permissions which may confuse those who are used to the standard unix chmod permission sets. The need to authenticate everything and everyone may sometimes cause problems for people who have no idea how to handle authentication. XFS is a high-performance 64-bit journaling file system created by Silicon Graphics and ported to the Linux kernel. XFS is supported by most Linux distributions i.e., Debian and REDHAT. XFS supports a maximum file system size of 500 TB and a minimum file size of 16 TB. An XFS file system can be shrunk only by backing up, re-installing, and restoring, e.g. using xfsdump and xfsrestore. Samba uses netbios which is not the world's most efficient network protocol.

De-centralized ISP log management and lack of standard for ISP log format and retention has motivated us to design and implement a centralized log management system where hadoop distributed file system will be implemented due to limitation of other popular distributed file systems namely NFS and CIFS. Apache spark performs faster than map reduce on executing no-sql query and ranger security suite provides best access control across distributed file system. Considering the volume and necessity of ISP user's log, the research issues of the paper are set as follows:

- Review the features of all DFS. Choose highly reliable, resilient DFS for big data.
- Review and analysis of log mandate, format and propose a common log format.
- Security of proposed DFS. Ensure confidentiality of stored log, integrity and availability of proposed DFS.
- Implementation of proposed DFS with 3 nodes and optimization of DFS using open source software resources.

- Perform log analysis and simulation to obtain desired results like best performance of read, write latency and security features. Optimization of DFS using open source software resources.

II. LITERATURE REVIEW

Deepa et al. state that the components of HDFS file system, Big Data and processing of this terabytes to multiple petabytes which will help to manage and process large volume of data [4]. And also addresses the fundamental of HDFS file system with architecture and challenges. It is also mentioned how storing less number of larger files rather than huge number of smaller files. V. Sajwan et al. state about HDFS architecture, name node and Data Node configuration [5]. HDFS is designed and developed to scale up from a one server to thousands of machines device with extremely high degree of ability.

BTRC has described about ISP license and internet user statistics. This is about the total number of internet subscribers which has already reached 92.466 Million at the end of October, 2018 [6]. This survey provides a clear view of necessity of centralized log server for keeping the track of internet usage. CoreStack addresses the initiative to improve transparency of ISPs in India [7]. This paper will describe how to preserve access log for all users and share log files with central regulatory body using log mandate.

Internet has significant contributions to our life. Most people are connected to internet for 24 hours using BWA and WIFI device which in turn connects to local ISP and WIMAX/3G/LTE/4G internet service provider. Local ISP's are maintaining their own log servers where customers' internet session is logged using different format [8]. The Indian ISPs have to comply with the directions issued by the Department of Telecommunications (DoT). In its initiative to improve transparency, the DoT had mandated ISPs to maintain logs of Internet Protocol Detail Record (IPDR) and Network Address Translation (NAT).The directive also instructed storage of log data using format for one year by every ISP owner itself.

HDFS is a distributed file system designed to run on x86 processor based server. HDFS is highly fault-tolerant and is designed to be deployed on low-cost hardware [9]. HDFS provides high read, write throughput access to application data and is suitable for applications that have large data sets. Features of HDFS includes hardware failure, streaming data access using POSIX semantics [10], large data set, data replication, the communication protocol layered on top of the TCP/IP [11] and remote procedure call (RPC) [12].

Apache Sentry, an open source project by Cloudera is an authorization module for Hadoop that offers the granular, role-based authorization required to provide precise levels of access to the right users and applications [13]. It supports for role-based authorization, fine-grained authorization and multi-tenant administration [14].

Apache Knox is a security gateway that provides a single point of authentication and access gateway for various Hadoop services in a cluster. It provides a perimeter security solution for HDFS. It supports various authentication and token verification scenarios. Knox manages security across multiple clusters and versions of Hadoop. It also provides SSO solutions, and allows integrating other identity management solutions such as LDAP, Active Directory (AD), and SAML based SSO and other SSO systems [15].

Project Rhino provides an integrated complete data security solution to the Hadoop ecosystem [16]. It provides a token based and single sign-on solution. It offers Hadoop crypto codec framework and implementation to provide block level encryption for the data stored in Hadoop. It supports key distribution and management so that Map-Reduce can decrypt data block and execute the program as per requirement. It also enhances the security of HBase by offering cell level authentication and transparent encryption for table stored in HDFS. It supports audit logging framework for easy audit trails. Spark is a no-sql query processing tool developed by Apache to process programs written in a high-level concise language and distributes the execution of its tasks onto DFS.

It achieves this through an API such as Data Frames and Datasets built atop Resilient Distributed Datasets (RDDs) – a distributed dataset abstraction that performs calculations on large clusters in a fault-tolerant manner. Spark's architecture improves RDD's performance significantly:

- Spark allows users to take advantage of memory-centric computing architectures by persisting DataFrames, Datasets, and RDDs in-memory, enabling fast iterative processing use case such as interactive querying or machine learning.
- Spark's high level DataFrames and Datasets APIs also enable further intelligent optimization of user programs.
- Project Tungsten and Catalyst Optimizer as part of the Spark SQL engine significantly boosts spark's execution speed in many cases by 5-10 times.

III. PROPOSED SYSTEM ARCHITECTURE

Addressing the problem of existing ISP log management process and studying the relevant work of other countries a system architecture is proposed in this paper. It contains 1 master node and 3 slave nodes for DFS to interconnect ISP log servers. Proposed DFS, log analysis process, access control policy, security features and data protection process is discussed. A common log format for all ISP is also shown in this section.

A. Proposed DFS Model

HDFS exposes a file system namespace and allows user data to be stored in files. Internally, a file is split into one or more blocks and these blocks are stored in a set of Data Nodes. The Master Node executes file system namespace operations like reading, closing and modifying files and directories. It also determines the mapping of blocks to Slave Nodes. The Slave Nodes are responsible for serving read and write requests from the file system's clients. The Slave Nodes also perform block creation, deletion and replication upon instruction from the Master Node. The details of nodes and functionalities are described in Table I.

The Name node makes all decisions regarding replication of blocks by receiving a heartbeat and a block report from each of the Data Nodes in the cluster. Reply message of a heartbeat implies that the Data Node is functioning properly. A block report contains a list of all block's status on a Data Node.

TABLE I. ISP LOG ANALYTICS NAME NODE AND DATA NODE INFORMATION

SL	*Node Name*	*Disk Space*	*RAM*	*IP Address*	*Role*
1	Name Node	50 GB	12 GB	103.103.35.137	Name Node
2	Data Node 1	50 GB	12 GB	103.103.35.137	Data Node, Spark Server
3	Data Node 2	50 GB	7 GB	103.103.35.138	Data Node
4	Data Node 3	50 GB	7 GB	103.103.35.139	Data Node, Apache Ranger

A Data Node stores data in the distributed file systems. A functional file system has more than one Data Node, with data replicated across them. On startup, a Data Node connects to the Name node and spinning until that service comes up. It then responds to requests from the Name Node for file system operations. Our proposed architecture will include all ISP's as Data Node. Here Data Nodes are represented by debian, node1 and node2 respectively.

B. Log analysis over Proposed DFS

We've deployed spark at master node 'debian' to process query over ISP internet access log in CSV format. Apache Spark has had two core contexts that are available to the user. The sparkContext made available as sc and the SQLContext made available as sqlContext, these contexts make a variety of functions and information available to the user. The sqlContext makes a lot of DataFrame functionality available while the sparkContext focuses more on the Apache Spark engine itself. In our proposed deployment, Apache Spark 2 contains just one context - the SparkSession.

Databricks is a platform for running Apache Spark which provides a host of features to help its users be more productive with Spark. It's a point and click platform for those that prefer a user interface like data scientists or data analysts. However, this UI is accompanied by a sophisticated API for those that want to automate aspects of their data workloads with automated jobs. To meet the needs of enterprises, Databricks also includes features such as role-based access control and other intelligent optimizations that not only improve usability for users but also reduce costs and complexity for administrators. In Spark environment, a DataFrame is a distributed collection of data organized into named columns. It is equivalent to a table in a relational database or a data frame but with richer optimizations under the hood. Data Frames can be built from a wide range of sources such as: structured data files, tables in Hive, external databases, or existing RDDs.

C. Access Control of Proposed DFS

Apache Ranger is a security solution to enable, monitor and manage comprehensive data security across the HDFS file system. The vision with Ranger is to provide centralized and comprehensive security across the Apache Hadoop ecosystem using attribute based access control (ABAC). With the advent of Apache YARN, the Hadoop platform can now support true data lake architecture. Organizations can run multiple workloads, in a multi-host environment. Data protection within HDFS needs to evolve to support multiple use cases for data access, while also providing a framework for central administration of security policies and monitoring of user access.

Policies are set centrally and enforced by plugins. Plugins are simple libraries that run within data processing application and enforce policies enforces set in the policy manager. Apache Ranger goes beyond access control, with the ability to dynamically masking data when data is accessed in Hive. Centralized policy management and distributed enforcement around various data processing and storage engines using ranger is illustrated in Fig. 1.

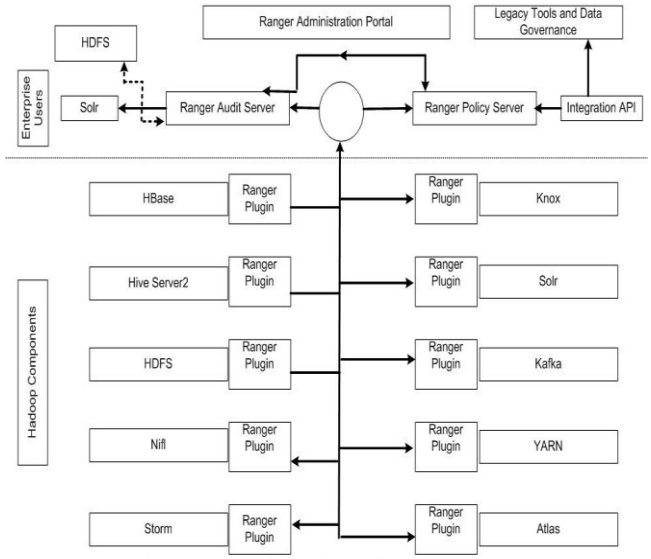

Fig. 1: Proposed security policy management

D. Security Features of Proposed DFS

Initial Hadoop distribution, Data Nodes do not enforce control. Due to this reason, the malicious user can read arbitrary Data Node blocks from Data Nodes and bypass the access control restrictions or write the garbage data in Data Nodes. Therefore, any user can submit a job to Job Tracker and could arbitrarily execute the job. The Yahoo Hadoop community realized the security issues and enforced robust security controls through Kerberos as the authentication mechanism for Hadoop. The latest version of HDFS accomplished the goal using following security goals.

- Kerberos remote procedure call (RPC) for mutual authentication of users, their processes, and services.
- Internet clients implement their pluggable authentication called SPNEGO (Simple and Protected GSSAPI).
- Generic Security Service Application Program Interface and Negotiation Mechanism.
- Access control lists of users and groups on HDFS.
- Delegation tokens and subsequent authentication checks.
- Master Node takes access control decisions for Data blocks access.
- Job tokens ensure task authentication to verify that tasks could do only assigned tasks.
- Enforce network level encryption to ensure security.

E. Proposed Log Format for ISP

In order to store all ISP log and merge into a single file, we have proposed a common log format. This format will include unique ISP id having at least 4 digits and a subscriber id to be provided by his/her related ISP. The individual ISP

log is merged and rotated once a week or a month according to the total data volume. The common log format is provided in Table II.

TABLE II. PROPOSED LOG FORMAT

SN	*Field attribute*	*Description*
1	ISP ID	ISP identification number
2	Subscriber ID	Subscriber identification number
3	Name of Person / Organization	Full name of person or organization
4	Address	Customer address
5	Contact No	Customer phone number
6	Alternate Contact no	
7	Email Address	Customer email address
8	User ID for Internet	Identification number
9	IP Address Assigned	Customer's assigned real IP address
10	Static / Dynamic IP Address Allocation	Natted IP address
11	Source port of the public IP address	Source port for real IP address
12	BST Start Time (hh:mm:ss)	Timestamp in Bangladesh time
13	BST End Time (hh:mm:ss)	Timestamp in Bangladesh time

Log rotation policy is determined according to retention policy and duration i.e., preserve log for six, twelve months or two years. For long duration, log rotation's frequency will be executed frequently to maintain minimum space of any log file and merge all ISP's log file to produce a single file called 'NAT.csv' for processing using below script as illustrated in Fig. 2.

```
#!/bin/bash
OutFileName="NAT.csv"                    # Fix the output name
i=0                                      # Reset a counter
for filename in ./*.csv; do
 if [ "$filename"  != "$OutFileName" ] ;  # Avoid recursion
  then
   if [[ $i -eq 0 ]] ; then
     head -1  $filename >  $OutFileName   # Copy header if it is the first file
   fi
   tail -n +2  $filename >> $OutFileName  # Append from the 2nd line each file
   i=$(( $i + 1 ))                       # Increase the counter
fi  done
```

Fig. 2: ISP Log merge script

IV. IMPLEMENTATION

A. DFS Cluster Environment

Master and Data Nodes must have similar version of debian linux kernel and java or jre version for ideal hadoop's distributed file system. The master node in clusters host the various storage and processing management services. For each Data Node to communicate with its Master Node, we have configured '/etc/hosts' file at all three nodes to add the IP address of the three servers. The master node will use an ssh-connection to connect to other nodes with key-pair authentication to manage the cluster without password. The key based password less SSH connectivity among three nodes will be configured from master node [17]. After completion of key based SSH communication among nodes, from master node 'debian' below commands is executed to synchronize node 1 and 2 hadoop binary installation directory.

```
# rsync -avzh /home/hadoop/ hadoop@node1:/home/hadoop/
# rsync -avzh /home/hadoop/ hadoop@node2:/home/hadoop/
```

After completion of HDFS Data Block replication, Yarn, configuration of Data Nodes, cluster is started. Apache spark is extracted and hdfs user profile is configured to perform sql jobs. Spark's job execution, completed SQL query's duration can be monitored from web gui using url http://103.103.35.137:4040 as shown in Fig. 3.

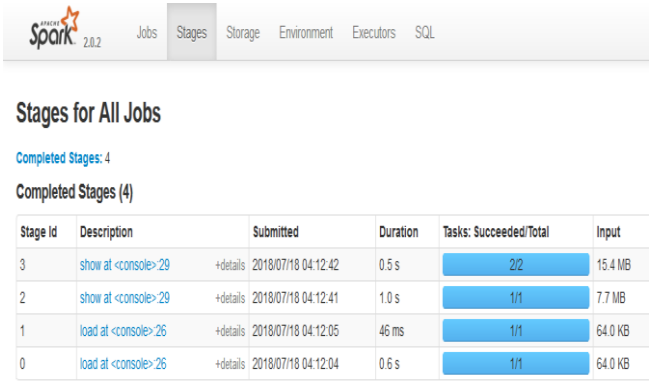

Fig. 3: Apache Spark Web GUI

B. Implementation of Access Control

For access control, Apache Ranger has been installed and configured in third node of distributed file system and integrated with Log analytics. The Ranger administration portal can be accessed using url: 103.103.35.139:6080 where user named as Shazzad and Mahfuz has been created with admin and user role is shown in Fig. 4.

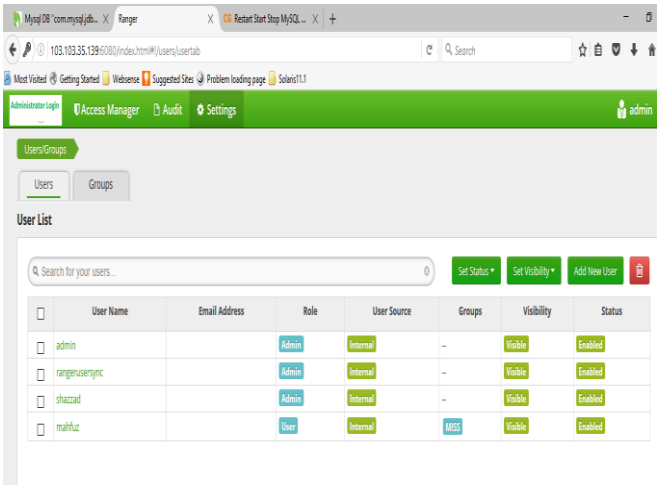

Fig. 4: Log analytics User and Group information

From Fig. 4, user name, role and status can be verified and add, delete, modification of privileges can be done. Audit of administrator and user activity can be accessed from the mentioned web page.

C. Secured Connectivity among Nodes

In order to ensure secured communication among name node and all Data Nodes, we apply following best practices for configuration of VPN and IPTABLE in participating hosts [18].

- Enable Host Based Firewall.

- Allow required Ports i.e. 50070, 8088, 6080 and restrict or deny access to all other ports,
- Configure IPSec tunnel between Master and Slave Nodes in shown in Fig. 5.

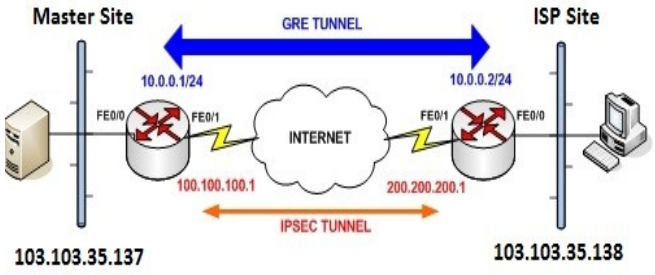

Fig. 5: IPSec over GRE tunnel configuration between Master and one ISP site

- Define access control list (ACL) to allow only master and slave nodes.
- Use strong cryptography key and passphrase for tunnel configuration.
- Allow authorized user or administrator to modify or update network configuration and log activities.
- Arrange for secondary or backup link connectivity between Name node and each Data Node.

D. Setup and Configure NFS for benchmarking

To setup NFS mounts for performance comparison with proposed DFS, one NFS server with three clients are configured. For sharing a directory with NFS, an entry is required in "/etc/exports" configuration file. A new directory named "isplog" in "/" partition is created to share with client server using below commands:

```
# vi /etc/exports
/isplog 103.103.35.137 (rw,sync,no_root_squash)     // NFS server share name
```

At the NFS client end i.e, from Data Node 2, check the nfsshare using below commands:

```
# showmount -e 103.103.35.137
Export list for 103.103.35.137:
/isplog 103.103.35.138
```

Above command shows that a directory named "isplog" is available at server having IP address "103.103.35.137" to share with Data Node 2. To mount that shared NFS directory at the client's node, following command will be used:

```
# mount -t nfs 103.103.35.137:/isplog /mnt/isplog
```

CIFS mount point is configured in the same way for performance comparison.

V. SIMULATION AND RESULTS

The architecture and relevant configuration of the proposed DFS is used to simulate and evaluate the performance of the file systems, query processing and security features. To evaluate the performance of log processing, a comparison between proposed query processing method and map reduce is performed. ISP log is used by Spark utility to perform search based on specific attribute and the latency of read, write operations shell be recorded in proposed DFS, NFS and CIFS shares respectively to draw performance comparison.

A. Data Collection

Our proposed solution processes user's internet activity log in real-time and for that purpose, we have collected ISP user's log from two ISP. User access log contains required information is shown Table III.

TABLE III. SAMPLE ISP USER INTERNET ACTIVITY LOG

Date Time	*Client IP*	*Src Port*	*Dst IP*	*Dst Port*	*Pop Name*
00:59.0	54.255.166.250	80	10.254.27.206	39389	104.30
00:59.0	10.254.31.76	51906	31.13.79.63	443	104.30
00:59.0	10.254.27.19	42978	47.88.65.224	6798	104.30
00:59.0	172.217.166.106	443	10.254.27.237	60589	104.30
00:59.0	43.245.142.146	443	10.254.31.202	38215	104.30

B. Experiments with Proposed Method

From below query using Spark's scala command shell, we can identify the client communicating with destination POP address in Table IV where connected clients source, source port, destination IP address, destination port no. and POP id through which the clients connect to internet are displayed.

```
scala>df.select("ClientIP","Src_Port","Dst_IP","Dst_Port","Pop_Name").show()
```

TABLE IV. SCALA OUTPUT

Client IP	*Src_Port*	*Dst_IP*	*Dst_ Port*	*Pop_Name*
54.255.166.250	80	10.254.27.206	39389	Cyber-POP-104.30
10.254.31.76	51906	31.13.79.63	443	Cyber-POP-104.31
10.254.27.19	42978	47.88.65.224	6798	Cyber-POP-104.32
172.217.166.106	443	10.254.27.237	60589	Cyber-POP-104.33

C. Comparison between Proposed Method and Map Reduce

Proposed Spark method can do processing in memory, while Hadoop MapReduce has to read from and write to a disk . As a result, the speed of processing differs significantly, Spark may be up to 100 times faster. However, the volume of data processed also differs. Spark's performance over map reduce may be obtained with work count programs performance which was tested and result is provided in Fig. 6. In Fig. 6, the analysis used three Data Nodes and processed up to 48 GB data and comparison of required time by hadoop's map reduce and spark are shown in the graph as blue (Hadoop) and red or orange (Spark). Fig. 7 and 8 shows that proposed DFS provides much better read and write latency respectively over NFS and CIFS. For 100 GB data read and write operation, latency of proposed DFS is lower than that of CIFS and NFS.

D. Security Comparison of Proposed DFS

Security comparison among NFS, CIFS and proposed DFS is described in below Table V.

TABLE V. SECURITY COMPARISON AMONG NFS, CIFS AND PROPOSED DFS

File System	*NFS*	*CIFS*	*Proposed DFS*
Architecture	File-based	File-based	Cluster based
Processes	Stateless	Stateful	Stateful
Naming	No central metadata server	No central metadata server	Central metadata server
Synchronization	No	No	Write-one-read-many
Session Requirement	No	Yes	Yes
Communication speed	Fast	Slow	Fast
Fault Tolerance	No	No	Yes
Security mechanism	No	Kerberos	Security in the form of AAA

From Table V it is found that the architecture of NFS and CIFS is file based protocol but proposed DFS is cluster based. NFS has stateless process, CIFS and proposed DFS have stateful process. There is no central metadata server for NFS and CIFS except proposed DFS. There is no synchronization in NFS and CIFS. Communication speed is fast in both NFS and proposed DFS. There is no security mechanism in NFS, kerberos in CIFS and AAA security in proposed DFS

Fig. 6: Comparison between proposed method and map reduce (3 Instances)

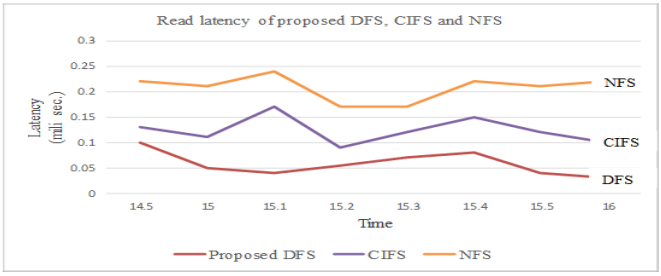

Fig. 7: Read latency of proposed DFS, CIFS and NFS

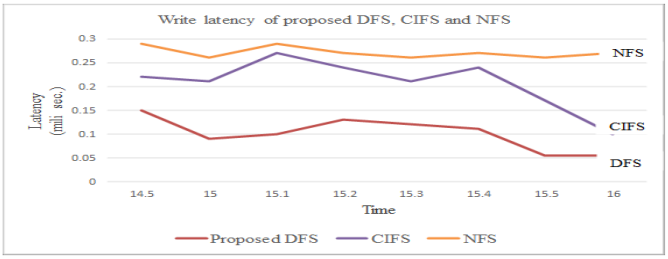

Fig. 8: Write latency of proposed DFS, CIFS and NFS

VI. CONCLUSION

In Perspective of Bangladesh a centralized log analytics system has been designed to access and monitor user's activity in internet using commodity hardware and open source software for cost optimization and rapid deployment. All experiment results regarding log analytics distributed file system implementation, map reduce algorithm, no-sql query using spark and access control features have been included. The log analytics system offers flexibility and ability to process large datasets. Our proposed solution will also preserve user activity log for a long duration to detect and investigate suspicious activity that occurred a long time ago.

Abstract*— In remote sensing image classification, really it is an intimidating when kernel supervised learning approaches stands in need of adequate amount of training samples. Often there is a vital problem for definition and acquisition of reference data. For Hyperspectral image classification, improved spectral information is required to make it suitable for ground object identification. In this paper, Support Vector Machine with RBF kernel (KSVM) and the spectral angle mapper (SAM) are used for performance comparison in terms of classification accuracy in Hyperspectral image classification. Kenel support vector machine is more preferable for the mastery to generalize better hyperplane when limited availability of training samples and separate the classes competently in a new dimension feature space. Experiments are performed on NASA Airborne Visible Infrared Spectrometer (AVIRIS) image and it shows KSVM outperforms SAM and obtains the highest accuracy. Due to more well-conditioned against the outliers, KSVM significantly reduced the classification complexities than SAM.

Keywords*— Spectral Information, Object Identification, Hyperspectral Images Classification, Support Vector Machine, Spectral Angle Mapper.

I. INTRODUCTION

Earlier scientists and geologists obtained land cover information through manual surveying by observing places on movable cars, bus or foot. In many circumstances, it was found that the above methods are not efficient and not practical in some location of the world. For example, suppose you have to implement this for large and remote areas. So now you might be thinking how much time and money should be required and also thinking if there are other way to do so. So manual surveying approach will practically require more expensive and consume more time.

The geographical land information is captured by mounting camera on aircraft and using the power of this technique, the researchers need to obtain land cover information in much shorter time. However, they found such method dependent on the weather to some extent for the increasing number of air accidents. In accordance with the development of modern space technologies, remote sensing satellite took the place of aerial photography technology where satellites captured land cover information by satellite's sensor. The cost slope is relatively slow down when this opportunity are created by satellite sensor than the aerial photography that makes the whole operation of monitoring land covers efficient and several places can be covered and observed at a time [1-3]. As a result, in a particular slot of time, the time to time changed land cover information detect effectively. By the change of land cover natural conditions and human activities related to environmental, agriculture and urbanization, it is essential to make accurate decision [4-7]. Previously different digital classification algorithms have been used to predict the nature and classes existent in those images such as Maximum Likelihood Classification (MLC), Vertex component analysis (VCA), Kernel Support Vector Machine (SVM) and Spectral Angle Mapper (SAM) etc. To overcome the lacking of MLC, SAM was got introduced. The Performance of these classifiers depends on the accurate selection of training samples. When the input dimension is high and the limited availability of training sample are presented, then the hyperspectral image classification is seriously daunted with poorly classified labeled training samples. To solve this problem, the alternative standard multiclass classifiers are developed. Spectral Angle Mapper (SAM) classifier is technique that matches each pixel in the input image with every end member for each class instead of matching it to the input training pixels [7]. The problem of this SAM classifier is that is does not considered the sub-pixels when the end member is selected and creates more problem for multiclass or heterogeneous earth surface. Again the development of the accuracy of classification can be obtained by the improved the kernel support vector machine which makes a good job of classification for Hyperspectral image [7-8]. By using SVM with RBF kernel, the optimal separation is obtained by generating a hyperplane between the classes considered. The support vector machine selects in the race of thousands of decision boundaries if pattern recognition has two classes that are linearly separable and select the one that has a minimized generalization error. By this, the decision boundary that has been taken into consideration has to be the one that has biggest margin between two class levels, where margin is equal to sum of the length to the hyper-plane of the two classes' closest point. By means of standard quadratic programming, the problem of maximizing the margin can be solved. The margin is measured by using closest distance between the data points and the hyper-plane and these data points are called support vectors [9-10]. Therefore, in term of counting, small numbers of support vectors are present. As detecting environmental and global ecology alter, main forwardness has to be taken about land cover and land use. Land use or land cover classification is an essential element; in there that element is made of different parameters. Different parameters are jointed together on the rule of necessities. Agricultural land, water, buildings, soil, fallow bare land, vegetations, and artificial cover are these that indicate the land cover and others seen on the land [11].

II. CLASSIFICATION TECHNIQUES

Two classification techniques are adopted in this study to classify the hyperspectral image classes.

A. Spectral Angle Mapper (SAM)

Spectral Angle Mapper (SAM) approach is a supervised technique that uses spectral angular information for the task of image classification. The SAM works well since it utilizes the spectral similarity between the reference spectra

and the image spectra [13-15]. SAM measures spectral similarity by calculating the angle between two spectras. This spectrum is a vector in a space with dimensionality that is equal to the number of spectral bands. The range of spectral angle is (0 to 1). Unlike the distance metrics it is possible to have a zero spectral angle even when the two vectors are not identical. Therefore this approach is not sensitive to albedo effect and illumination because the angle between two vectors is not variant according to the length of the vectors. SAM between two spectral signatures with L bands $\mathbf{S}_i = (\mathbf{S}_{il}...\mathbf{S}_{il})^T$ and $\mathbf{S}_j = (\mathbf{S}_{jl}...\mathbf{S}_{jl})^T$ is defined as,

$$\mathbf{SAM}\ (\mathbf{S}_i, \mathbf{S}_j) = \mathrm{Cos}^{-1}(\Theta_{si,sj}) \qquad (1)$$

where,

$$\theta(s_i, s_j) = \left(\frac{\sum_{i,j=1}^{L} s_i s_j}{\left[\sum_{i=1}^{L} s_i^2\right]^{\frac{1}{2}} \left[\sum_{j=1}^{L} s_j^2\right]^{\frac{1}{2}}} \right)$$

This classifier is robust against the solar illumination effect. Therefore it is said that the SAM is a robust classifier as it is effective to overcome to the shading effect to target reflectance characteristics. The major disadvantages created by SAM is that it considers the end members taken to classify an hyperspectral image by creating the genuine spectra of a reference material, where the heterogeneous earth's surface are present in many ways and make of mixed pixels.

B. *Support Vector Machine(SVM)*

This classification considers separate data sets for testing sets and training set. All the training set carries different target value and different characteristics. To predict the target values of the given test data by SVM that is the main goal of SVM. The nonlinear SVM is used to calculate the inner product of the mapped samples which avoids the difficulty in determining the mapping function ϕ and also the cost for calculation of the mapped samples and their inner product. Several typical kernels including linear, polynomial, and radial basis function (RBF). Though SVM is initially developed for two-class problems, It has been extended to deal with multiclass classification based on either combination of decision results from multiple two-class classifications or optimization on multiclass based learning [3]. In the first phase, SVM is used for initial training and classification. In the second phase, these results have been used for probability based modeling. The open-source library livSVM is used for initial training and classification of the aforementioned four datasets, and both the linear and the Gaussian radial basis (RBF) kernels are tested. For each group of datasets, all the data are normalized to [−1, 1] before SVM is applied. Through 10-fold cross validation, the best group of parameters, including the cost and the gamma value, are optimally determined. Eventually, the optimal parameters are used for classification. Without misclassification, a linear hyper-plane is unable to separate classes that are common cases. For this special case, a nonlinear separating hyper-plane can able to separate those classes. By using a nonlinear transformation function, data are mapped into a high dimension space. Data are expanded in high dimension space so that a linear separating hyper-plane can be developed [14]. This is the idea of a principle *Cover's theorem* on the *separability of patterns*. In the figure below that describes one that when two classes are in an input space, linear separating hyper-plane cannot separate two classes. A linear separating hyper-plane can be acquired wherein data has to be mapped in the high dimensional feature space [14].

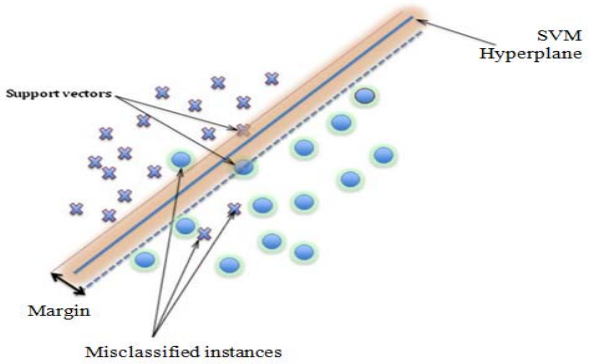

Figure 1: Linear support vector machine example.

Now Θ is a nonlinear transformation function that maps all data into a high dimensional feature space. Let there is a function *T*, that is said to be a kernel function, so that:

$$T(\mathbf{X}_i, \mathbf{X}_k) \equiv \Theta(\mathbf{X}_i) \cdot \Theta(\mathbf{X}_k) \qquad (2)$$

The kernel function Θ is replaced by the explicit form of Θ and dot product of the transformed vectors. Again, the less computationally intensive is provided by the use of the kernel function [15-17]. *Mercer's theorem* is used by a special case of dot product and the formation of the kernel function.

III. METHODOLOGY

In this paper, the research includes with three stages: data preprocessing, using standard feature selection method (statistical information measure feature selection), using Spectral Angle Mapper and SVM RBF kernel for classification and comparison of the results of those two methods.

A. *Data Pre-Processing*

We have worked with NASA Airborne Visible Infrared Spectrometer (AVIRIS) image. We have manipulated the image using Multispec tools application and 8 classes (Soy, Woods, Corn-nottill, Hay, Soy-till, Corn, Wheat, Corn-min) were taken in the image area among of all 16 classes are available in the dataset. We have taken five features more specifically five channels and studied on the classification accuracy results given by SAM and SVM based on them. That's why it is necessary to extract the best possible features by using standard feature selection method.

B. *Feature Extration*

During the selection and manipulation of some particular bands and features of our specified data set, our study has been involved with the feature extraction from the

specialized NASA Airborne Visible Infrared Spectrometer (AVIRIS) image data. For this we have used the mutual information based feature selection approach [16]. This approach is selected in this case for the feature selection because it selects the features that have enhanced discrimination power. The classification accuracy of MIFS features is also higher than the classification in the original space [16]. That is why we have used this method for the extraction of feature from our AVIRIS data set.

C. *Data Operation in Spectral Angle Mapper*

The SAM classifier is one of most emerging classification technique cause of calculating the similarity of spectra by creating the robustness against the influence of shading to underscore the target reflectance characteristics. For hyperspectral image classification, the Multispec tools are used.

D. *Data Operation in Support Vector Machine (RBF kernel)*

On the statistical information based feature selection of hyperspectral remote sensing image, the Kernel Support Vector Machine (SVM) is suitable for classification [14]. Nowadays, Kernel support vector machine is very emerging technique for hyperspectral image classification [17-19]. SVM is implemented to classify the multiclass problem by trickily creating KSVM directly, but due to the number of the classes essential for being correctly classified increases, parameters number for being estimated increases. KSVMs finally affect the classification performance in terms of accuracy. We use livSVM in matlab tools. We have implemented this operation by three steps; firstly, we have performed the input data scaling in the dimension [0 1], secondly we have performed the cross validation check to find out the best value of c(cost estimation factor value) and the gamma to carry out the testing of our referred AVIRIS data set. The values of c and gamma will be used to train our selected data values in accordance with the band value selected by feature selection. Finally we will calculate the training accuracy with best c and gamma value and get the best training accuracy for the specified values referred to as our extracted band values.

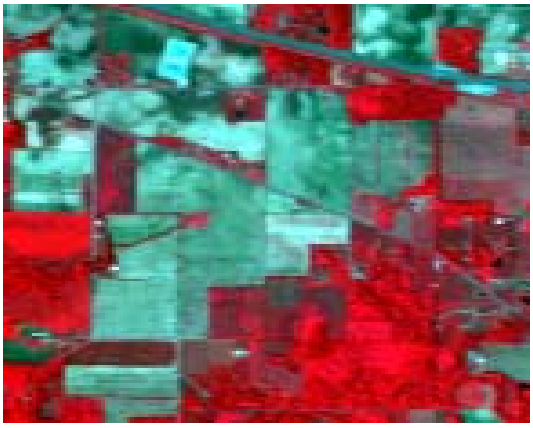
IV. Experimental Analysis

We have used NASA Airborne Visible Infrared Spectrometer (AVIRIS) hyperspectral data for our experimental analysis. Spectral Angle Mapper and Support Vector Machine (RBF Kernel) was used for classification. The performance of the proposed approach was evaluated using one real hypersepectral image data sets. Image consisted of 220 channels and was collected by an AVIRIS sensor over the agriculture area of Indian Pine in the north part of Indiana Sixteen classes is defined in the ground truth [23-26]. In this experiment, the numbers of eight classes are used. They are Soy, Woods, Corn-nottill, Soy-till, Hay, Corn, Wheat and Corn-min.

A. *Accuracy Assement*

For assessing the classification accuracy, the confusion matrix was used by using the ground truth image. In the experiment, the percentage of correctly classified pixels refers to the overall accuracy.

B. *Dataset Description*



The performance of the proposed approach was evaluated using one real hypersepectral image data sets. Image consisted of 220 channels and was collected by an AVIRIS sensor over the agriculture area of Indian Pine in the north part of Indiana Sixteen classes is defined in the ground truth [23-26]. In this experiment, the numbers of eight classes are used. They are Soy, Woods, Corn-nottill, Soy-till, Hay, Corn, Wheat and Corn-min.

Table 1: Classes used in the experiments for NASATA AVIRIS dataset

AVIRIS Dataset			
Class Name	**Class No**	**Train**	**Test**
Soy	1	96	168
Woods	2	170	130
Corn-nottill	3	96	126
Hay	4	120	128
Soy-till	5	110	105
Corn	6	56	30
Wheat	7	63	84
Corn-min	8	90	80
Total	8	801	851

C. *Experimental Result and performance analysis*

Spectral Angle Mapper classifier and KSVM is applied on AVIRIS Indian pine dataset ('92AV3C.lan) after performing extracting feature by using Standard feature extraction algorithm (Statistical Information based Feature selection-SIBFS) is used for best feature. The selected image bands are 193, 65, 31, 170, 2. In the experiments, 8 classes are used Soy, Woods, Corn-nottill, Soy-till, Hay, Corn, Wheat and Corn-min for the evaluation of the suitability of the feature selection. Table 2 shows the overall accuracy of the SIBFS selected features when using Kernel SVM. Error matrics are calculated for both training and testing performance shown Table 3 and Table 4 respectively when using Kernel SVM classifier. Table 5 shows the overall accuracy of the SIBFS selected features when using SAM. Error matrics are calculated for both training and testing performance shown Table 6 and Table 7 respectively when using SAM classifier. Finally overall performance of accuracy KSVM vs. SAM based on SIBFS are shown in Table 8 and graphically shown in Figure 3.

Table 2: Shows KSVM accuracy on SIBFS feature band

No. of features	KSVM Accuracy (%)
1(Using images band: 193)	60.549

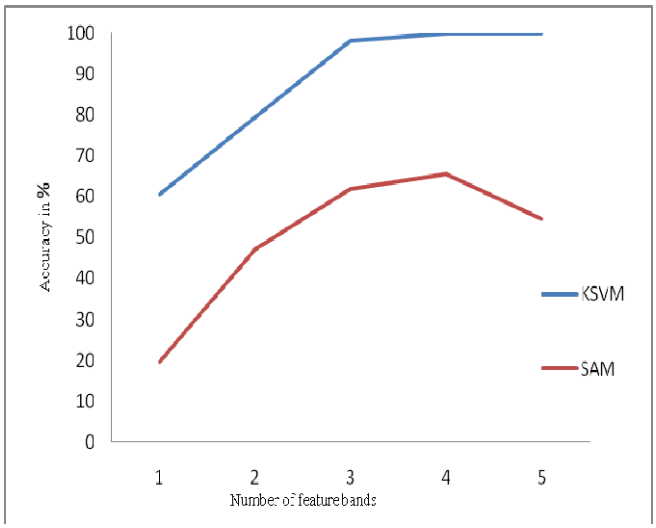

Figure 3: Performance of testing accuracy KSVM vs. SAM based on SIBFS.

V. CONCLUSION

From the performance analysis it is quite clear that KSVM provide better result than SAM. KSVM provide a good classification result due to creating an optimal hyper plane between the target classes and rest of the classes. It has the ability to separate the complex class pairs easily in the high dimensional space. KSVM also gives a good result since some classes are complex in structure and were not linearly separable. The main disadvantages of SAM classifier is that it chose the end members to classify an image by symbolizing the pure spectra of a reference material, in where the earth's surface is heterogeneous and made of mixed pixels. Hence the strength and weakness of the KSVM and SAM are analyzed.

***Abstract*—Microstrip patch antenna (MSA) has numerous applications such as aircraft, biomedical engineering, connected vehicles, cellular phones, satellites, smart grid, and spacecraft. Single MSA or MSA Array (MSAA) require low-cost materials with simple and inexpensive fabrication techniques. With the help of modern and highly precise printed-circuit technology it is possible to fabricate inexpensive and robust MSA/MSAA, which are compatible with microwave monolithic integrated circuit (MMIC) designs. Rectangular patch, one of the most popular patches, has different feeding techniques for impedance matching. Inset fed rectangular patch does not require any additional complex microwave circuit. Inset feeding mechanism can easily be optimized with the help of 3D simulation software. Very few investigations are made on inset fed MSAA, though several research papers can be found on inset fed rectangular MSA. In this paper a comparative analysis of edge fed and inset fed MSA/MSAA at 2.45 GHz frequency band is done using FR-4 and air substrates. It was found that the inset fed MSA with air substrate performs better when the directivities, gains, bandwidths and return losses are considered. Though FR-4 substrate is cheap and miniaturization of MSAA is better with FR-4 substrate.**

***Index Terms*—antenna radiation patterns, directivity, gain, microstrip patch, impedance matching.**

I. Introduction

While most of the advances in Microstrip patch antenna (MSA) and MSA array (MSAA) are due to military and space applications, the utility of this technology has been rapidly gaining interest in commercial sectors [1]. On the other hand the 5th generation (5G) wireless systems will depend on a huge number of smaller cells to offload the traffic from the cellular and from other wireless networks [2]. One of the distinctive features of 5G technology is its intrinsic flexibility of frequency spectrum, which will allow it to support different application in an efficient way, either using low-band below 1 GHz, mid-band from 1 GHz to 6 GHz, or high-frequency band above 6 GHz [3].

MSA and MSAA have applications in different technological areas such as aircraft, biomedical engineering, connected vehicles, cellular phones, satellites, smart grid, and spacecraft. A microstrip patch generally consists of a metallic patch, which may take many different forms, on a grounded plane [1]. A dielectric medium (with a particular dielectric constant), called the substrate, is placed between the radiating patch and the grounded plane.

Some of the characteristics of MSA/MSAA are radiation pattern, beam width, directivity, gain, bandwidth, quality factor, efficiency, polarization, and return loss. The specifications for military and space applications typically put emphasis on best performance with almost no constraint on cost. On the other hand commercial applications seek low cost components sacrificing some electrical performances [1]. MSA/MSAA for commercial applications require low-cost materials with simple and inexpensive fabrication techniques. Microstrip patch can be planar or non-planar. With the help of modern printed-circuit technology it is possible to fabricate inexpensive and robust MSA/MSAA, which are compatible with microwave monolithic integrated circuit (MMIC) designs. There exists different shapes of patches for different applications. Improvements in the properties of the dielectric materials and in design techniques have led to enormous popularity of MSA [4]. Among different shapes, the rectangular MSA is the most popular [1]. Fig.1 illustrates the basic structure of a rectangular shape MSA.

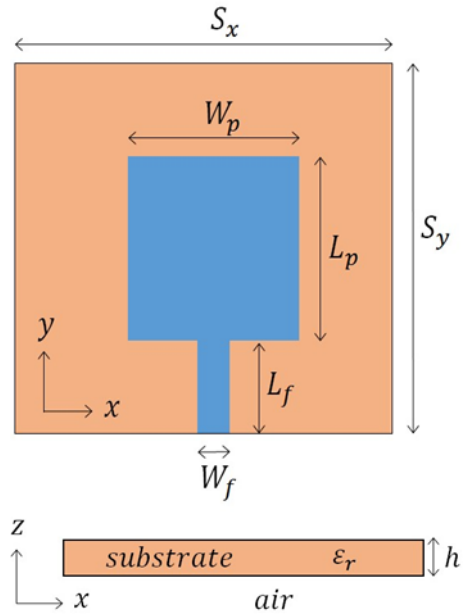

Fig. 1: Rectangular shape microstrip patch antenna.

There are several feeding techniques for microstrip patch antennas such as:

a. Aperture coupled feed
b. Coaxial probe feed
c. Microstrip transmission line feed:
    i. Edge feed-
        1. Center feed
        2. Offset feed
    ii. Inset feed
d. Proximity coupled feed
e. Quarter-wave line feed

Design complexities of MSA/MSAA increase with the miniaturization of the antenna. MSA is a resonant device and suffers from a number of limitations such as low bandwidth, low gain, low power handling capacity and higher return loss. An effort to improve one parameter, such as return loss, results in other complexities. Detailed methods of antenna designs and optimization processes are described in [1], [5]- [8].

In this paper we have investigated the performances of edge fed and inset fed rectangular patches at 2.45 GHz frequency band. We have used the HFSS software as a simulation tool.

The paper is organized as follows. Section II describes the performances of inset fed rectangular patch in terms of its input impedance. Section III makes a comparative analysis of edge fed and inset fed MSA using two different substrates, one is air and the other is FR-4. In section IV an analysis of 4×1 edge fed MSAA and 4×1 inset fed MSAA are made. Section V describes the fabrication of an inset fed rectangular MSA with copper material and air substrate. Finally, conclusion is made in section VI.

II. Analysis of the Input Impedance of Inset Fed Rectangular Patch Antenna

Each feeding method has its own merits and demerits. The feed structure affects the bandwidth [1], directivity, gain, and return loss of antenna. With inset feed patch, a good matching condition can be obtained [1], [6] and a wide impedance bandwidth can also be achieved [6]. Inset feed method does not require any additional matching arrangement. It is achieved by properly controlling the inset position and width. Fig. 2 shows an inset microstrip line fed antenna. Inset feed scheme is an easy feeding scheme since it provides ease of fabrication with simplicity in modeling as well as impedance matching [1].Though improvement procedures of inset feed patch have not been widely investigated in case of array antenna.

Two different feed mechanisms of patch antennas, resonating around 720 MHz, using a probe feed and an inset microstrip-line feed, have been discussed in [6]. The notch cut of the inset fed rectangular patch decreases the effective length of the excited patch surface current, and the effect is larger for a larger notch [6]. An antenna occupying more space in a spherical volume will have a wider bandwidth (BW) [1]. One way of increasing the BW is to increase the height (h) of the substrate. Increase in height also results in more efficient antenna. However higher value of h may result in surface waves that travel within the substrate. These phenomena result in undesired radiations which may cause other problems.

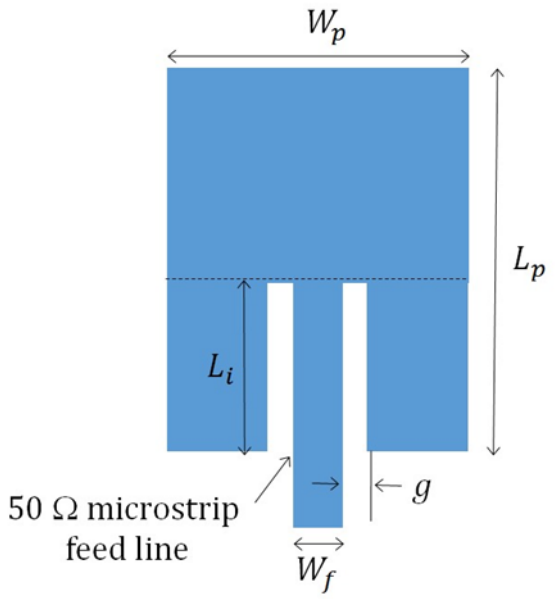

Fig. 2: Inset fed Microstrip Patch Antenna.

By inset feeding of the MSA, the input impedance can be decreased. Let's assume that the patch length is $L_p = 0.61\lambda$ (i.e. $\lambda = 1.64L_p$). The phase change in the length L_i (Fig. 2) is expressed as $\frac{2\pi L_i}{1.64L_p} = 1.22\pi(\frac{L_i}{L_p})$. If sinusoidal current distribution is assumed, the departure from the end by a distance L_i will increase the current by $\cos(1.22\pi\frac{L_i}{L_p})$. At the same time the voltage will also decrease in magnitude by the same amount as that when the current increases [1].

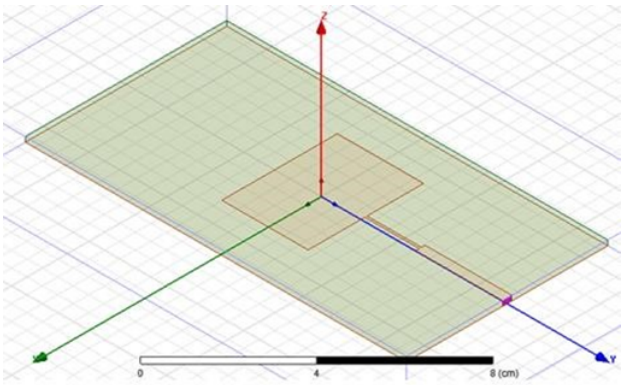
The input impedance ($Z = \frac{V}{I}$) can be expressed as [1]:

$$Z_{in}(L_i) = \cos^2(1.22\pi\frac{L_i}{L_p})Z_{in}(0) \quad (1)$$

Where $Z_{in}(0)$ is the input impedance if the patch is fed at the end.

As an example let $L_i = 0.245L_p$, $\cos(1.22\pi\frac{L_i}{L_p}) = 0.59$ and $\cos^2(1.22\pi\frac{L_i}{L_p}) = 0.35$. Therefore a $0.245L_p$ inset feed would decrease the input impedance by 35%.

III. Performance comparison of edge fed and inset fed rectangular patches using different substrates



In this section, we have compared the performances of edge fed and inset fed rectangular MSA at the resonant frequency 2.45 GHz ($\lambda = 122.45mm$). Equations for the different dimension of patch antenna can be found in [5], [10]. With inset feed patch, a good matching condition can be obtained and a wide impedance bandwidth can be achieved [6]. We've used HFSS antenna design kit [11] to calculate the dimensions of patch and feed lines. We have considered two different substrates in the simulations, one is FR4 ($\epsilon_r = 4.4$) and the other one is air ($\epsilon_r = 1$). Thickness (h) of the substrate was kept constant at 1.6 mm in every scenario.

Different dimension of edge fed and inset fed patches (with FR4 and air substrates) are summarized in Table I. Use of substrate with lower relative permittivity results in lower impedance, better radiation pattern, increased antenna bandwidth, and higher antenna efficiency [1]. A higher value of permittivity should be used in the locations where no power is to be used radiated (e.g. transmission lines). Higher values of permittivity also result in 'shrinking' of the patch antenna which is good for cell phone use where a very little space is available for antenna placement. Fig.3 shows the snapshots of the patches from HFSS simulations. Fig.4 shows the return losses of the edge fed and inset fed rectangular patches with the FR-4 and air substrates. A summary of the simulation results is included in Table II.

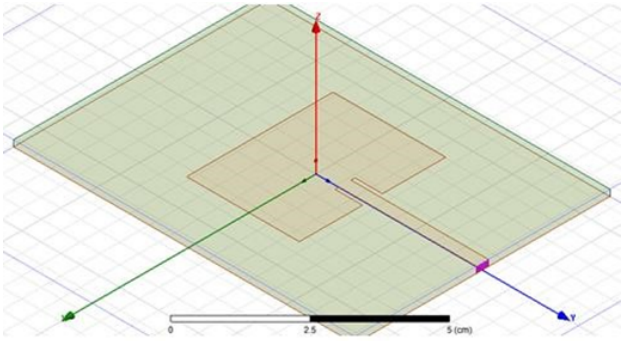


TABLE I: Dimensions (in mm) of edge fed and inset fed patches with FR-4 and air substrates.

Type of substrate ⇒		**FR-4 substrate** ($\epsilon_r = 4.4$)		**Air substrate** ($\epsilon_r = 1$)	
Feed-method ⇒		**Edge feed**	**Inset feed**	**Edge feed**	**Inset feed**
50 Ω feed line	Length	27.96	27.96	51.02	27.96
	Width	3.06	3.06	7.87	3.06
100 Ω feed line	Length	17.6	-	30.61	-
	Width	0.72	-	4.06	-
Patch	Length	27.85	28.7	57.5	58.9
	Width	37.3	37.3	61.2	61.2
Ground/ Substrate	Length	122.96	86.86	227.73	164.97
	Width	65	65	101	101
Inset cut	Length	-	7	-	15.8
	Width	-	1	-	1

It can be observed from Fig.4 and Table II that the inset fed MSA performs better than the edge fed one from all the perspectives of impedance bandwidth, directivity, gain, and return loss. The results with air substrate are also better than the corresponding results with FR-4 substrate. The gain of the inset feed with air substrate was 7.18 dB. In [1] the gain of a rectangular patch with air substrate was estimated within the range of 7∼9 dB. If the effective permittivity increases by a factor of 4, the required length decreases by a factor of 2 [1]. One disadvantage of using the air substrate is the larger antenna size that can be observed from Table I. Generally the higher value of permittivity is used to miniaturize the patch [1]. During the simulations, the length of the inset fed patch had to be increased slightly in order to keep the constant resonant frequency of 2.45 GHz. The aspect ratio (≈ Length/Width) of the patch controls the resonant frequency [1].

(a) Edge fed microstrip patch.

(b) Inset fed microstrip patch.

Fig. 3: Edge fed and inset fed microstrip patches from HFSS simulations (substrate: FR-4).

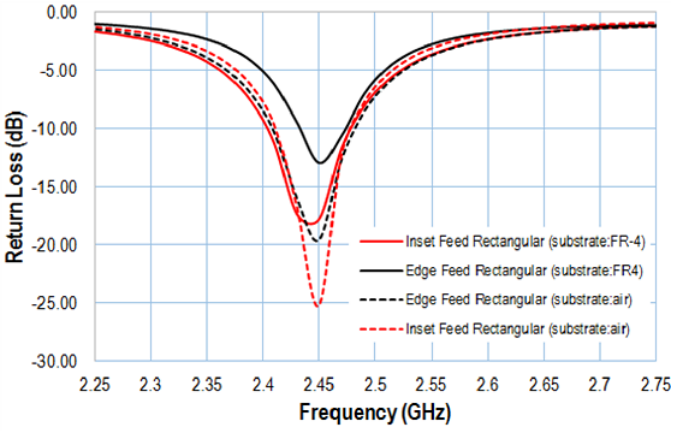

Fig. 4: Return loss characteristics of edge fed and inset fed microstrip patch antennas with FR-4 and air substrates (resonant frequency: 2.45 GHz).

IV. Performance comparison of 4×1 array antenna with edge fed and inset fed rectangular patches

Array antennas are used in order to enhance the gain and reduce the beamwidth. Generally the larger the number of antenna elements used, the higher the gain and the narrower the beamwidth can be achieved. A power efficient MSAA with minimum side lobe level (SLL) and narrower beamwidth will be required in next generation wireless systems. Some existing MSAA applications have drawbacks of larger beamwidth, higher SLL and lower gain. For example, Traffic Collision Avoidance System (TCAS) requires compact MSAA with higher gain, narrower beamwidth, and perfect directional radiation pattern [12]. MSAA should optimize multiple criteria simultaneously such as beam forming gain with very narrow beamwidth, lower side lobe level [13], less interference [14], polarization, power efficiency, and required bandwidth.

We have designed 4×1 MSAA with two different feeding techniques mentioned in the previous sections and with FR-4 substrate . We have used quarter-wave transformer with the feed systems for impedance matching purposes. Fig. 5 shows 4×1 MSAA with inset feed technique. Inter-element spacing of the array was 0.5λ in this case. Simulation results of the two MSAA are summarized in Table II. It can be seen from Table II that the values of all the four parameters (return loss, directivity, gain, and bandwidth) have been improved in case of MSAA in comparison to those of single patch antenna cases. Though the return loss is the lowest in case of inset fed MSAA (Fig. 8), other parameters are comparatively inferior to those of edge fed MSAA. Fig. 6 shows the directivities and 3D radiation patterns of two different MSAA.

V. Development of inset fed rectangular patch with copper material and air substrate

Our research group is in the process of developing and testing inset fed MSA/MSAA which resonate at 2.45 GHz and other ISM bands. Fig.7 shows an inset fed rectangular MSA antenna which was fabricated from copper plate and air was used as substrate between the patch and ground plate. We have chosen the copper material since it is available in the local market. We have selected the air as a substrate in order to check the performance of the inset fed patch with air. The results of the antenna testing will be included in future publications.

TABLE II: Summary of performance-parameters of edge fed and inset fed rectangular patches at 2.45 GHz.

Antenna type ⇒	**Single MSA**				**4×1 MSAA**	
Substrate type ⇒	**FR-4**		**Air**		**FR-4**	
	Edge feed	**Inset feed**	**Edge feed**	**Inset feed**	**Edge feed**	**Inset feed**
Return Loss (dB)	-12.97	-17.80	-19.60	-25.28	-18.28	-26.00
Directivity (dB)	5.41	5.62	6.6758	7.1913	11.032	9.876
Gain (dB)	2.306	2.5	6.6756	7.1822	7.63	5.97
Bandwidth (MHz)	40	80	70	70	110	90

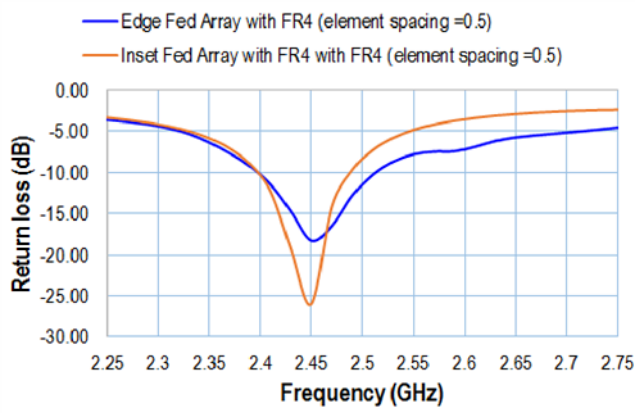

Fig. 8: Return losses of edge fed and inset fed microstrip arrays (4×1) with FR-4 substrate (resonant frequency 2.45 GHz).

VI. Conclusions

In this paper a comparative analysis of different characteristics of edge fed and inset fed rectangular microstrip patches are done at 2.45 GHz. The investigation results, which have been described in the paper, revealed that the better impedance matching can be made through inset feed of rectangular array without any complex modification of microwave circuits. Inset fed rectangular patch antenna performed better than the edge fed patch when impedance bandwidths, directivities, gains and return losses were compared. Though research findings on single patch can be found in different publications, research investigations on edge fed and inset fed rectangular array have not yet been widely published. It has been seen through HFSS simulations that return loss in case of inset fed array, which is -26 dB, is better than that of edge fed array. Return loss in case of edge fed array was -18.28 dB. Better return loss of inset fed array was obtained through optimization of the dimensions of inset fed patch. The investigation results reported in this paper would be helpful in implementation of inset fed rectangular microstrip antennas in future wireless applications.

Abstract— **Graphene has opened the floodgate for a plethora of new applications in the field of communication due to its outstanding electrical and optical properties. In this paper, three types of Graphene antenna arrays, i.e. rectangular, circular and triangular are designed to operate around 3THz on a silicon (ϵ_r = 11.9) substrate. A single band to dual band operation is achieved for all three types of Graphene antenna arrays at THz frequency range by changing the height of the silicon substrate, which has not been reported before. In comparison to rectangular and circular antenna arrays, triangular antenna array exhibits better performance in terms of S_{11}, VSWR, BW and Radiation Efficiency with an S_{11} of -39.44dB, VSWR of 1.024, BW of 103.4GHz and a staggering efficiency of 99.11%, which is the highest Radiation Efficiency, reported so far for Graphene antenna array application.**

Keywords—graphene; array; antenna

I. INTRODUCTION

Over the last decades, wired communication mediums are reaching their limits and according to Edholm's law, the wireless data rates have doubled in every 18 months [1]. Future generation communication systems will need to have data rates as high as 100 Gbit s^{-1} or more. With the increasing demand of high-speed data transmission, exploitation of the new higher band of frequencies is becoming a must. For this purpose, Terahertz communication has been considered a decisive wireless technology. Its spectral band lies in between the microwave and mid infrared with a span of frequencies between 0.1-10 Terahertz [2].

The main constraint of Terahertz communication is its high path loss due to atmospheric molecular absorption, which restricts its distance of communication. That is why Terahertz communication is applicable to LAN and PAN networks. In addition to this, implementation of Terahertz transceiver and efficient antennas remains challenging. GaN based HEMTs have already shown f_c >450GHz, f_{max} >600GHz [3] and InP based HEMTs have shown f_c >600GHz, f_{max} >1.2THz [4]. This transistor technology is already used to build MMIC amplifiers, which are reported to exhibit data rate as high as 25 Gbit s^{-1} [5]. The implementation of sources, detectors and modulators operating at Terahertz band will enable Terahertz communication feasible within few years.

Typical metallic antennas of micrometer sizes tend to resonate at optical range of frequencies of several hundreds of Terahertz [6]. These antennas suffer from a significant amount of shortcomings such as signal and channel attenuation due to their low carrier mobility at such high resonant frequencies.

Graphene based antennas can be a solution for this purpose. Graphene is an astonishing material with stunning electrical and optical properties. It is a 2D version of Graphite with carbon atoms arranged in a honeycomb lattice of single layer [7]. Most importantly, it can resonate at Terahertz frequency band [8]. Graphene possesses extremely high carrier mobility in the range of 8000-10000 $cm^2 V^{-1} s^{-1}$, which may reach as much as 200,000 $cm^2 V^{-1} s^{-1}$ at room temperature, and a Young's modulus of 1.5 TPa, which makes graphene one of the strongest materials with immense carrier velocity [2]. This astonishingly high carrier mobility enables Graphene based devices to operate at Terahertz band. The amazing thing about Graphene is that, it is tunable by changing its chemical potential and relaxation time and it possesses better radiation efficiency than typical metallic antennas [9]. It also supports SPP wave propagation, which makes it a precious material in the research field of communication. In the terahertz band, plasmonic nature of the graphene causes extreme solidity, where metals behave as non-plasmonic conductors. Graphene makes the creation of dynamically tunable devices possible [10].

In recent times, there have been some works on Graphene based rectangular, triangular and circular patch antennas at Terahertz range [11-13]. Works are also done on Graphene antenna arrays. In [14], multiple resonance is achieved by changing the number of Graphene layers for UT shaped Graphene antenna array. In [15], rectangular patch Graphene antenna array for 5G application is investigated. Previously, Graphene based dual band antennas are realized by creating slots and stubs near the radiating edges and using backing cavity [16].

In this paper, we are presenting Graphene based triangular, rectangular and circular 2x1 patch antenna arrays with Graphene as a radiating patch on a silicon substrate (ϵ_r = 11.9) operating around 3THz. We achieved a single band to dual band conversion for changing the substrate height of each type of 2x1 patch antenna arrays at Terahertz range and compared the results. Achieving dual band operation by changing the substrate height of different types of Graphene antenna arrays at Terahertz band haven't been investigated before and it provides an easier way of achieving dual band operation at micrometer size than creating slots and this signifies the novelty of this work. Previously, the highest radiation efficiency reported for Graphene antenna array application was 93.14% for rectangular Graphene patch on a Kapton substrate [15]. We have achieved higher radiation efficiency of 99.11% for triangular 2x1 patch antenna array for silicon (ϵ_r = 11.9) substrate which is also a novelty of this work.

II. GRAPHENE MODELLING

We used Computer Simulation Software (CST) Microwave Studio for our 2x1 Graphene antenna array design. CST provides Graphene material for optical applications. In [9], Llatser et al. showed that the resonance of Graphene depends heavily on its chemical potential (μ_c) and relaxation time (τ). The conductivity of Graphene is defined as,

$$\sigma(\omega) = \frac{2e^2 K_B T i}{\pi\hbar^2\left(\omega + i\tau^{-1}\right)} \ln\left[2\cosh\left[\frac{\mu_C}{2K_B T}\right]\right] \quad (1)$$

Here, the electron charge is **e**, the temperature is **T**, the Boltzmann constant is $\mathbf{K_B}$, the chemical potential is $\boldsymbol{\mu_c}$ and the relaxation time is $\boldsymbol{\tau}$. From Equation (1), we can see that chemical potential has a direct relation to the conductivity of Graphene hence a change of chemical potential will change the conductivity of Graphene. The increase of chemical potential increases the resonant frequency and increase in relaxation time produces strong resonant characteristics. Chemical doping is used for changing chemical potential of Graphene. Our Graphene parameters are: Temperature (T) = 300K, Chemical Potential (μ_c) = 0eV, Relaxation Time (τ) = 2ps and Graphene sheet thickness = 0.1um.

III. RECTANGULAR PATCH ARRAY DESIGN

Our rectangular antenna is designed to resonate around 3THz. On the basis of cavity model, the resonant frequency of a rectangular antenna of length L is given by [17] as,

$$f_{10} = \frac{c}{2L\sqrt{\varepsilon_r}} \quad (2)$$

Where c is the light speed and ϵ_r is substrate's dielectric constant. The width W of the antenna has a minor contribution to the resonant frequency. The geometry of the antenna array is given in Fig. 1 and the dimensions are given in Table I.

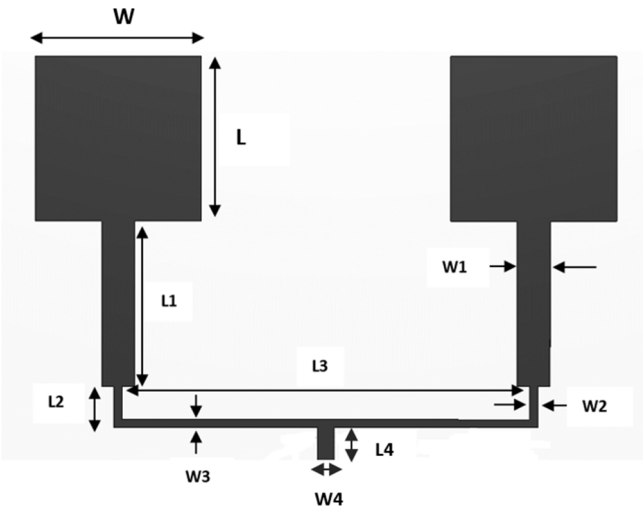

Figure 1. Geometry of 2x1 rectangular Graphene antenna array designed in CST

TABLE I. DIMENSIONS OF PATCH ANTENNA ARRAYS

Dimensions	Rectangular (μm)	Circular (μm)	Triangular (μm)
Width*Length(W*L) / Radius(a) / Side Length(a)	10*10	5	10
Patch height	0.1	0.1	0.1
W1	2	2	2
L1	10	10	10
W2	0.5	0.4	0.5
L2	2.05	2	2.5
W3	0.5	0.5	0.5
L3	25.5	25.5	25.5
W4	1	1	1
L4	2	2	2

IV. CIRCULAR PATCH ARRAY DESIGN

Our circular antenna is designed to resonate around 3THz. The resonant frequency calculation is given by [18] as,

$$f_r = \frac{1}{2\pi\sqrt{\mu\varepsilon}}\left(\frac{X'_{mn}}{a}\right) \quad (3)$$

Where ***a*** is the radius of the patch. For the lowest order mode, Bessel function zeros X'_{mn} becomes 1.8414 and equation (3) becomes,

$$f_r = \frac{1.8411c}{2\pi a\sqrt{\varepsilon_r}} \quad (4)$$

The geometry of the antenna array is given in Fig. 2 and the dimensions are given in Table I.

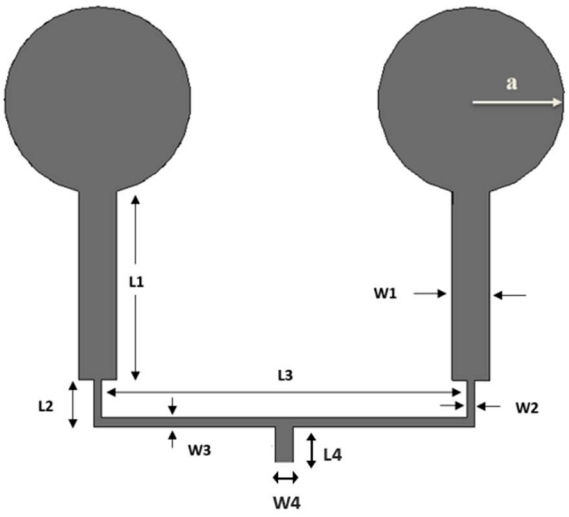

Figure 2. Geometry of 2x1 circular Graphene antenna array designed in CST

V. TRIANGULAR PATCH ARRAY DESIGN

Our triangular antenna is designed to resonate around 3THz. The geometry of the antenna array is given in Fig. 3 and the dimensions are given in Table I.

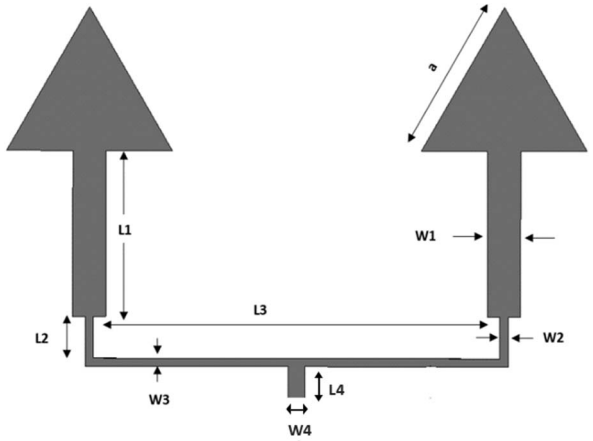

Figure 3. Geometry of 2x1 triangular Graphene antenna array designed in CST

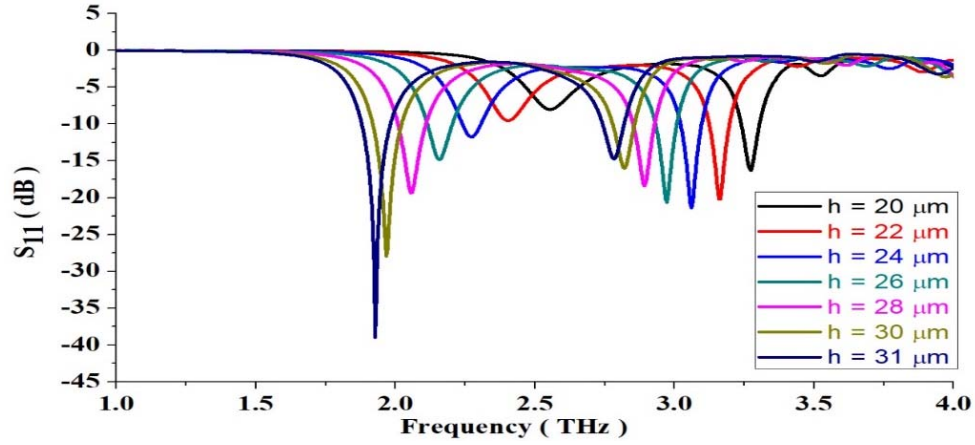
The resonant frequency calculation for an equilateral antenna of the lowest mode is given by [19] as,

$$f_{10} = \frac{2c}{3a_e\sqrt{\varepsilon_r}} \qquad (5)$$

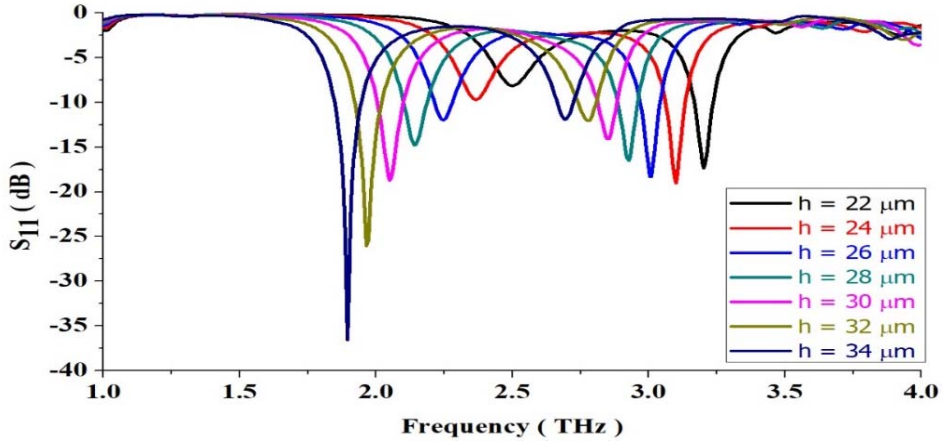
Where a_e is the effective side length of the antenna and is given as,

$$a_e = a\left[1+2.199\left(\frac{h}{a}\right)-12.853\left(\frac{1}{\sqrt{\varepsilon_r}}\right)\left(\frac{h}{a}\right)+16.434\left(\frac{1}{\varepsilon_r}\right)\left(\frac{h}{a}\right)+6.182\left(\frac{h}{a}\right)^2-9.802\left(\frac{1}{\sqrt{\varepsilon_r}}\right)\left(\frac{h}{a}\right)^2\right] \qquad (6)$$



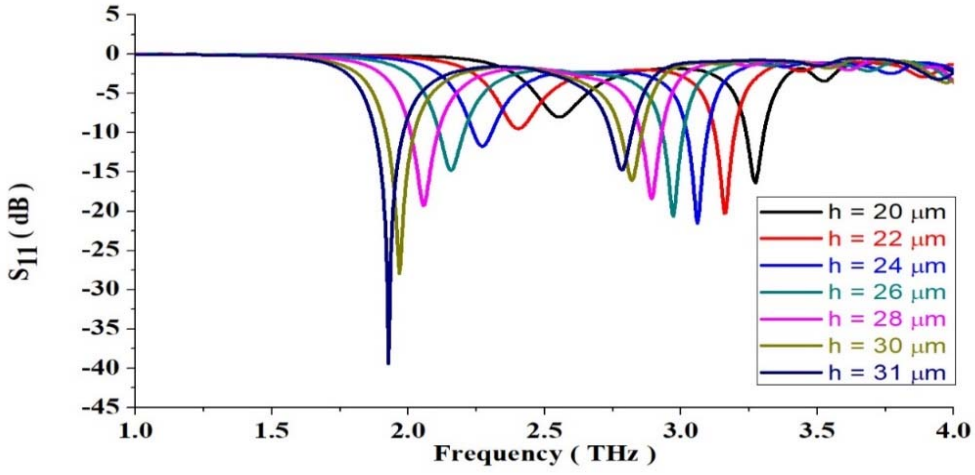
VI. SIMULATION & RESULTS

The complete simulation process is carried out by CST microwave studio, which supports EM field solver. We used microstrip line feeding to excite the antenna arrays with discrete port as exciter and we used quarter wave (λ/4) transformers for matching the input impedance of 50Ω to the patch antenna's load impedance. We simulated each of the antenna arrays and analyzed different antenna parameters, e.g. Return Loss S_{11}, Voltage Standing Wave Ratio (VSWR), Bandwidth, Radiation efficiency, Directivity and Gain for different height of the Silicon substrate.



For antennas, the Return Loss S_{11} should be less than -10dB to be considered as workable frequency band. The VSWR should be close to 1 for perfect impedance matching. The Radiation Efficiency should be as high as possible (less negative in dB), where 0dB means perfect antenna with 100% efficiency. The higher the values of Directivity, BW and Gain the better the antenna performance. Table II shows the antenna performance for each antenna array with different values of the substrate height.

TABLE II. PERFORMANCE OF GRAPHENE ANTENNA ARRAYS



Array Type	Substrate Height-h(μm)	Resonant Frequency-f_c (THz)		Return Loss-S_{11}(dB)		VSWR		Bandwidth (GHz)		Radiation Efficiency(dB)		Directivity(dB)		Gain(dB)

Figure 4. S_{11} of (a) Rectangular (b) Circular (c) Triangular 2x1 Graphene antenna array

From table II and Fig. 4 we can see that for each type of antenna array, as we increase the substrate height, second band arises from a single band operation. As the substrate height increases, it creates enough space for the fringing field to excite another higher order mode to be propagated. The fringing-filed effect of antenna is related to patch dimension and substrate height [20]. The new order mode resonates alike the first mode but at a separate frequency because of distinct phase constants. Thus, a single to dual band conversion is achieved for all three-antenna arrays.

The highest single band gain is 5.388dB for triangular antenna array operating at 3.16THz with substrate height h=22 µm. The highest dual band gain is exhibited by rectangular array with h=24µm. The second band operates at 3.06THz with a Gain of 5.223dB. Fig. 5 shows the 3D & 2D radiation pattern for rectangular array with h=24µm. The best S_{11} and VSWR exhibited by triangular array with h=31µm. The first band operates at 1.928THz with a very good S_{11} of -39.44dB and VSWR of 1.021. The fringing field increases the BW of the antenna and we can see the proof from the results in table II. The highest single band BW is 72.81GHz for triangular array with h=22µm. For dual band operation, the highest BW is 103.4GHz for triangular array with h=30µm operating at 1.968THz. The highest Radiation efficiency is exhibited by triangular array with h=28µm. The second band operates at 2.892THz with an astonishing Radiation efficiency of -0.0388dB or 99.11% and a Gain of 5.062dB. Fig. 6 shows the 3D & 2D radiation pattern for triangular array with h=28µm. The amazing thing is that the lowest Radiation efficiency for triangular Graphene antenna array is -0.0832dB or 98.1%. The lowest Radiation efficiency for rectangular Graphene antenna array is -0.0836dB or 98.09% and in case of circular array the lowest Radiation efficiency is -0.5487dB or 88.1%. So, we can see that, all the three types of Graphene antenna arrays are highly efficient.

VII. CONCLUSION

In this paper, we presented an approach for gaining dual band operation from a single band operation by increasing the height of the silicon substrate for three types of antenna arrays. We have seen from the results that for all the three types of Graphene antenna arrays, i.e. rectangular, circular, triangular a single band to dual band conversion is achieved. In comparison to other two types of antenna arrays, the triangular antenna array shows better performance in case of Radiation efficiency, S_{11}, VSWR and BW. A staggering 99.11% antenna efficiency is achieved for triangular antenna array operating at 2.892THz for substrate height h=28µm. Circular antenna array exhibits Radiation efficiency greater than 88.1% for different substrate heights and rectangular antenna array exhibits Radiation efficiency greater than 98.09% for different substrate heights. All the three antenna arrays are highly efficient.

***Abstract*—Full-duplex (FD) is significantly better than half duplex (HD) as it transmits and receives data signal simultaneously at the same frequency channel. But one of the major challenges in this technique is self-interference (SI). To our best knowledge, for the first time, we introduce a system model for 5^{th} generation up-link communication exploiting distributed antenna system (DAS) to reduce SI to an extent and thus making the overall network performance better. This proposed DAS is modified version of the conventional one. It uses separate transmitter and receiver whereas traditional DAS uses transceiver which is highly exposed to SI. After comprehensive simulation of the proposed system, its performance is evaluated and compared with the existing DAS technology under different parameters and scenarios. The SINR performance of proposed system model appears to be better than the traditional DAS.**

***Index Terms*—Full-duplex; Distributed Antenna System; Self-Interference; Signal to Interference plus Noise Ratio; 5G.**

I. Introduction

Rapid growth of consumer demand for worldwide wireless communication has motivated the development of fifth generation mobile communication system. For meeting the demand of increasing users, in-band FD communication has been proposed as a new scheme in 5G which doubles the capacity compared to HD [1-2]. The main aspect of FD is the simultaneous utilization of transmission and reception at the same frequency by a single user increasing the transmission rate which will enable mobile operators to maximize the use of the limited frequency bandwidth they are given [3]. Although using FD, user capacity will be raised, a major drawback of this technology, SI degrades the overall network performance rendering this technology impractical. To suppress this additional deleterious signal, numerous methods have been proposed for SI cancellation [4-6].

Since wireless networks use transceiver for communication, the closely-spaced transmitter and receiver antennas makes the system suffer high magnitude of SI. This paper proposes a new model of DAS implementing FD by isolating the transmitter and receiver and therefore, reducing the effect of SI in the main signal. Analysis is presented and the proposed system model is compared with the traditional DAS using FD and path loss parameters standardized by 3^{rd} Generation Partnership Project (3GPP) demonstrating the effect of SI on both models [7].

Traditional DAS has been designed to increase network capacity solving coverage problem by re-using existing infrastructure [8]. Although, DAS have been implemented originally to cover dead spots in indoor wireless communication systems, this system can also be utilized to expand system capacity with reduced transmit power providing a better coverage in cellular communication. Because of analytical simplicity, DAS is used for uplink performance [9-10]. It can be recognized through investigation that our proposed model produces better performance.

This paper is organized as follows. Section II illustrates an elaborate description of our proposed system model. Section III elucidates the path loss model as well as the systemic evaluation of SINR calculation for the proposed model. Section IV provides the performance analysis and compares it with traditional DAS. Finally, Section V concludes the paper by summing the analysis.

II. System Model

Fig.1 illustrates the proposed in-band FD system model for up-link communication using DAS. The proposed system model exploits a macro cell in a homogeneous network consisting of a receiver approximately at the center and multiple transmitters distributed within the receivers perimeter. This model presents separate transmitter and receiver where every transmitter and receiver works individually not as a transceiver since SI increases as the distance between the transmitter and receiver decreases. Furthermore, different cell uses different frequency band which are orthogonal to each other resulting in zero inter-cell interference. In this model a single user is placed randomly in the cell at a time considering no user to user interference. Here a User Terminal (UT) connects to the nearest transmitter which transmits signal and the receiver which receives signal, both working individually. Since same frequency is used for transmission and reception simultaneously, the receiver of DAS will receive the received signal of UT as well as a portion of the transmitted signal from the transmitter as SI. For a traditional DAS depicted in Fig. 2,

in case of implementing FD, interference degrades the SINR output resulting in a far worse signal strength and crosstalk as all the nodes work as transceivers. During a phone call, UT sends and receives signal from the same node resulting in major SI.

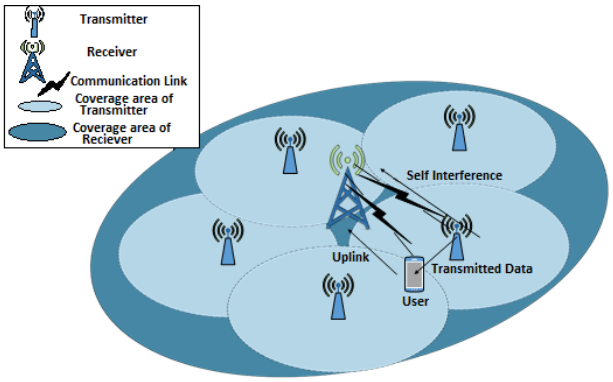

Fig. 1. Proposed model for full-duplex up-link communication exploiting DAS

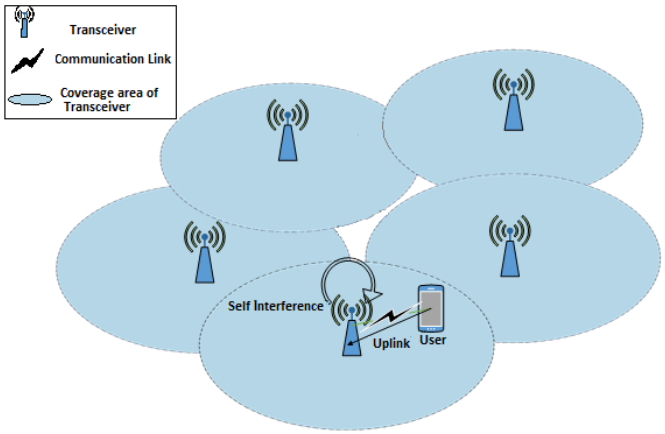

Fig. 2. Full-duplex up-link communication exploiting Traditional DAS

III. Theoretical Analysis

To meet the demand of the rapid growth of consumers 3GPP has introduced a new path loss model for 5G. This model supports higher frequencies (above 6 GHz up to 100 GHz). This model is also applicable for Line of Sight (LOS) and Non Line of Sight (NLOS) scenarios having log normal shadow fading with some basic criteria like distance between Base Station (BS) and UT, UT height, BS height, etc. [7]. In our proposed method, we have taken this path loss model into consideration and evaluated the received power by the Receiver from UT and the SI power from transmitter. Considering the peak to peak distance between Receiver/Transmitter and UT is three dimensional distance (d_{3D}), the linear distance between Receiver/Transmitter and UT is two dimensional distance (d_{2D}), the following equations for outdoor Users are as follows: [7]

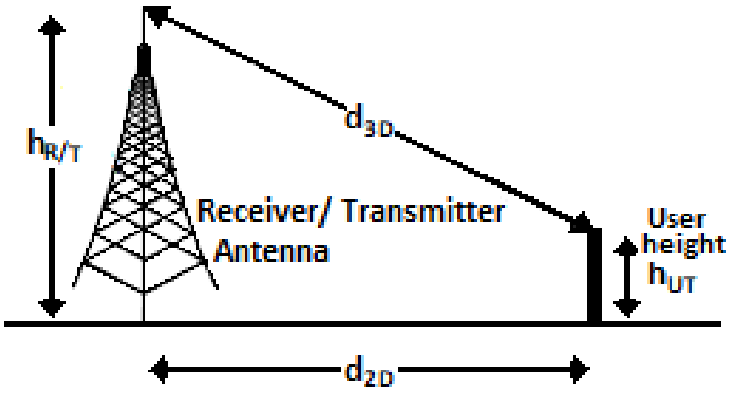

Fig. 3. d_{2D} and d_{3D} for outdoor users.

From Fig. 3,

$$d_{3D} = \sqrt{(d_{2D})^2 + (h_{R/T} - h_{UT})^2} \tag{1}$$

here,
$h_{R/T}$ = Receiver / Transmitter height
h_{UT} = UT height

When the receiver is connected to UT we take receiver height (h_R) into consideration and transmitter height,(h_T) when UT is connected to transmitter for this path-loss model. The path-loss model equations for LOS and NLOS for Urban Macro (UMa) and Rural Macro (RMa) outdoor along with all the parameters are described below:

A. Path-Loss Equation for UMa:

1) For LOS:

$$\text{PL}_{UMa-LOS} = PL_1 \quad \text{for}\,(10m \le d_{2D} \le d'_{BP}) \tag{2}$$

$$\text{PL}_{UMa-LOS} = PL_2 \quad \text{for}\,(d'_{BP} \le d_{2D} \le 5Km) \tag{3}$$

where,

$$PL_1 = 32.4 + 20\log_{10}(d_{3D}) + 20\log_{10}(fc) \tag{4}$$

$$PL_2 = 32.4 + 40\log_{10}(d_{3D}) + 20\log_{10}(fc) - 10\log_{10}((d'_{BP})^2 + (h_{R/T} - h_{UT})^2) \tag{5}$$

$$\text{and} \quad d'_{BP} = 4h'_{R/T}h'_{UT}fc/c \tag{6}$$

Here,

Center frequency is fc ;
The effective antenna heights at the Receiver/Transmitter (in meters), $h'_{R/T} = h_{R/T} - h_E$;
The effective antenna heights at the UT (in meters), $h'_{UT} = h_{UT} - h_E$;
Breaking point distance is d'_{BP} ;
The variance, $\sigma_{SF} = 4$ for shadow fading.

2) For NLOS: Keeping the parameters unchanged, the path-loss for UMa-NLOS scenarios, $PL_{UMa-NLOS}$ is given by:

$$PL_{UMa-NLOS} = \max(PL_{UMa-LOS}, PL'_{UMa-NLOS}) \quad for\ (10m \leq d_{2D} \leq 5Km) \tag{7}$$

where,

$$PL'_{UMa-NLOS} = 13.54 + 39.08\log_{10}(d_{3D}) + 20\log_{10}(fc) - 0.6(h_{UT} - 1.5) \tag{8}$$

For this case, the variance σ_{SF}= 6 for shadow fading.

B. Path-Loss Equation for RMa:

1) For LOS:

$$\text{PL}_{RMa-LOS} = PL_1 \quad \text{for}\,(10m \leq d_{2D} \leq d_{BP}) \tag{9}$$

$$\text{PL}_{RMa-LOS} = PL_2 \quad \text{for}\,(d_{BP} \leq d_{2D} \leq 5Km) \tag{10}$$

where,

$$PL_1 = 20\log_{10}(4\pi d_{3D} fc/3)) + 0.002\log_{10}(h)d_{3D} + \min(0.03h^{1.72}, 10)\log_{10}(d_{3D}) - \min(0.044h^{1.72}, 14.77) \tag{11}$$

here, variance σ_{SF}= 4 for shadow fading.

$$PL_2 = PL_1(d_{BP}) + 40\log_{10}(d_{3D}/d_{BP}) \tag{12}$$

$$\text{and} \quad d_{BP} = 2\pi h_{R/T} h_{UT} fc/c \tag{13}$$

here, d_{BP} is Breaking point distance and variance σ_{SF} becomes 6 for shadow fading.

2) For NLOS: The parameters and ranges are similar to LOS. The path loss equation for NLOS-RMa scenarios, $PL_{RMa-NLOS}$ is:

$$PL_{RMa-NLOS} = \max(PL_{RMa-LOS}, PL'_{RMa-NLOS}) \quad for\ (10m \leq d_{2D} \leq 5Km) \tag{14}$$

where,

$$PL'_{RMa-NLOS} = 161.04 - 7.1\log_{10}(W) + 7.5\log_{10}(h) - (24.37 - 3.7(h/h_{R/T})^2)\log_{10}(h_{R/T}) + (43.42 - 3.1\log_{10}(h_{R/T}))(\log_{10}(d_{3D}) - 3) - (3.2(\log_{10}(11.75h_{UT}))^2 - 4.97) + 20\log_{10}(fc) \tag{15}$$

here, variance σ_{SF} becomes 8 for shadow fading.

C. Received Power and SINR Calculation:

The following equation is used for calculating both the received power and SI power,

$$P_r = P_T - P_L - X \tag{16}$$

where,

$$P_r = Received\ Signal\ Power,$$
$$P_T = Transmitted\ Power$$
$$P_L = Path\ Loss,$$
$$X = Shadow\ Fading$$

Calculation of received power from the UT for up-link ,

$$P_r = P_T(UT) - P_L(UT) - X \tag{17}$$

Calculation of received SI power from the transmitter,

$$P_i = P_T(T) - P_L(T) - X \tag{18}$$

The SINR calculation for our proposed model is as follows:

$$SINR = \frac{P_r}{P_i + P_n} \tag{19}$$

where, P_n is the thermal noise power for one resource block in LTE.
In case of traditional DAS system, the value of SI power of transceiver is same as the value of transmitted power from the transmitter, $P_T(T)$ as there is no presence of path loss or shadow fading.

IV. Results & Discussions

Using the path loss model equations for LOS and NLOS for UMa and RMa outdoor along with all other parameters standardized by 3GPP provided in Section III, SINR performance is evaluated for our proposed Tx-Rx isolated DAS and a comparison with traditional DAS is demonstrated to mitigate the effects of SI. Parameters used for this analytical simulation with their values are displayed in Table I and II for UMa and RMa respectively.

The following Fig. 4 and Fig. 5 delineate the comparison of SINR performance between our proposed and traditional DAS for different frequencies. The graphs are shown for UMa LOS and NLOS scenarios respectively. From these plots it is clear that although SINR performance enhances with the decrease in frequency for both models, the output of traditional DAS is

TABLE I
SIMULATION PARAMETERS FOR UMa SCENARIOS [7]

Parameters	Value
Antenna height of Transmitter (h_T)	20m
Antenna height of Receiver (h_R)	25m
Antenna height of UT (h_{UT})	2m [1.5m $\leq h_{UT} \leq 22.5m$]
Receiver range	4Km
Effective environment height (h_E)	1m
Effective Antenna height of Transmitter (h'_T)	19m
Effective Antenna height of Receiver (h'_R)	24m
Effective Antenna height of UT (h'_{UT})	1m
Light velocity (c)	$3 \times 10^8 ms^{-1}$
Transmitted power of Transmitter ($P_T(T)$)	43 dBm
Transmitted power of UT ($P_T(UT)$)	23 dBm
Thermal noise power (P_n)	-121.45 dBm

TABLE II
SIMULATION PARAMETERS FOR RMa SCENARIOS [7]

Parameters	Value
Antenna height of Transmitter (h_T)	20m [10m $\leq h_{DAS} \leq 150m$]
Antenna height of Receiver (h_R)	35m [10m $\leq h_R \leq 150m$]
Antenna height of UT (h_{UT})	1.5m [1m $\leq h_{UT} \leq 10m$]
Receiver range	4Km
Average building height (h)	15m [5m $\leq h \leq 50m$]
Average street width (W)	20m [5m $\leq W \leq 50m$]
Light velocity (c)	$3 \times 10^8 ms^{-1}$
Transmitted power of Transmitter ($P_T(T)$)	43 dBm
Transmitted power of UT ($P_T(UT)$)	23 dBm
Thermal noise power (P_n)	-121.45 dBm

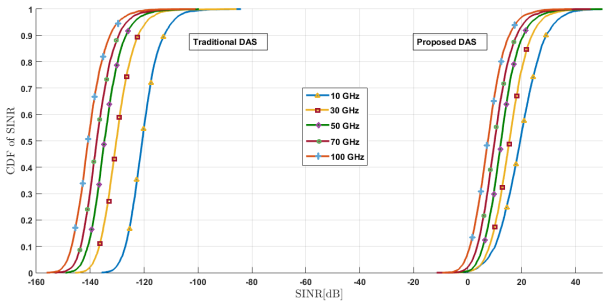

Fig. 4. Comparison between proposed and traditional DAS varying frequency for Urban Macro (LOS).

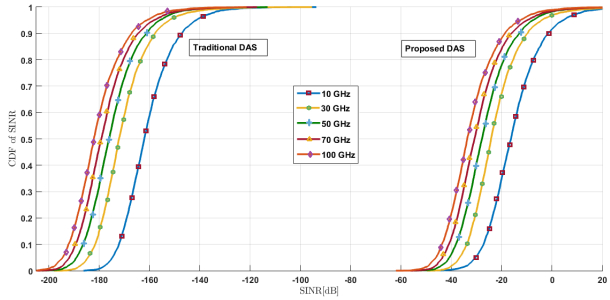

Fig. 5. Comparison of SINR performance between proposed and traditional DAS varying frequency for Urban Macro (NLOS).

always far worse due to the receiver antenna of the transceiver being highly exposed to the unwanted transmitted signal of its transmitter antenna which is SI. On the other hand, the proposed model gives a better output as the transmitter and receiver are separated and SI is reduced by creating distance between them.

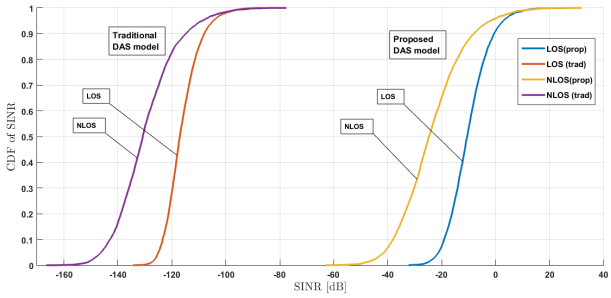

Fig. 6. Comparison of SINR performance between proposed and traditional DAS for Rural Macro (LOS and NLOS) keeping the center frequency fixed at 7 GHz.

Fig. 6 compares the SINR output between our proposed and traditional DAS for Rural Macro LOS and NLOS scenarios keeping the center frequency fixed at 7 GHz. According to the graph the traditional DAS shows high SI and worse performance while the proposed model gives a better output.

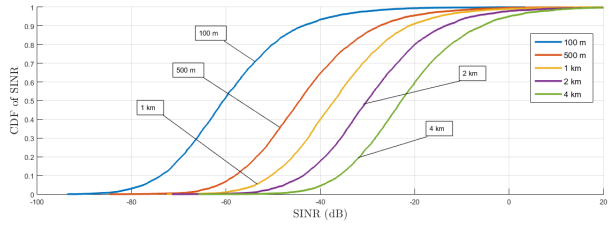

Fig. 7. SINR performance of proposed DAS for RMa-NLOS varying transmitter distance at 7GHz.

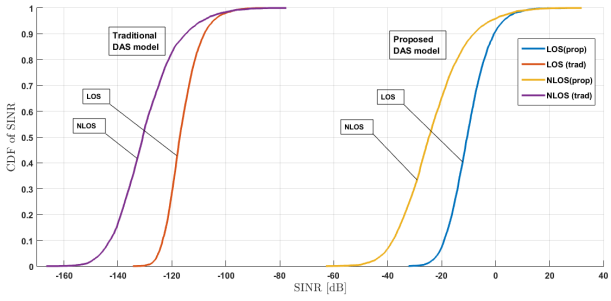

Fig. 8. SINR performance of proposed DAS for UMa-LOS varying transmitter distance at 50GHz.

SINR performance of proposed DAS for RMa-NLOS and UMa-LOS varying transmitter distance from receiver keeping the frequency fixed at 7 GHz and 50 GHz respectively are explained by using Fig. 7 and Fig. 8 respectively. As the distance increases between the transmitter and the receiver the

SI decreases resulting in a better performance. In the figures, the performance becomes saturated as the distance increases. It is also observed that SI is lowest and the SINR performance is quite better when the distance between transmitter and receiver is greatest (4 km).Varying distance for traditional DAS has no effect on SINR performance as every node works as transceiver.

V. Conclusion

The proposed system model presented in this paper comprises of two technologies: FD communication and DAS. Simulations are evaluated for both Urban and Rural outdoor case scenarios with various parameters to enumerate their impacts on the proposed and traditional network. After analysis, it is found that, for traditional DAS (where the nodes perform as transceiver), the SINR was worse due to a huge amount of SI. But for the proposed DAS (with the same parameters), the SINR was much better in comparison. The performance of SINR for 5^{th} generation communication network is better when a lower frequency is used. Furthermore, SI degrades the overall system performance when transmitter is closest to the receiver. Gradual increase in distance reduces SI and enhances the output of the system. This model can be further used for indoor scenarios and down-link channel.

***Abstract*—Analysis is developed for a Circular Polarization Division Multiplexing Quadrature Phase Shift Keying (CPDM-QPSK) with direct detection optical transmission system considering the impact of the crosstalk(Xtalk) owing to cross-polarization(XPol) induced crosstalk by arbitrary misalignment of the SOPs. A thorough analysis is demonstrated to acquire the output expression of the Signal to Cross-talk plus Noise Ratio (SCNR) for a direct detection CPDM-QPSK receiver. Considering the Maxwellian distribution of the random misalignment angles, the outcome of Bit Error Rate (BER) performance is presented ultimately. Moreover, cross-polarization affects the BER performances and thus the system suffers a significant deterioration from the expected results. It can also be observed that, the system suffers power penalty of 0.18, 0.92 and 4.44 dB for misalignment angle of 10, 11 and 12 degrees respectively at BER of 10^{-9}.**

***Index Terms*—cross-polarization; crosstalk; circular polarization division multiplexing; direct detection; quadrature phase shift keying.**

I. Introduction

The transmission capacity demand which is ever-growing in optical transmission systems has made it necessary to increase the spectral efficiency by implementing different techniques of transmission. Circular Polarization Division Multiplexing (CPDM), which involves Right Circular Polarization (RCP) and Left Circular Polarization (LCP) is an efficient technique for making the spectral efficiency of fiber-optic communication systems quadrupled. Every state of polarization Right Circular Polarization and Left Circular Polarization of two independently modulated signals at the same wavelength are transmitted in this technique [1]. By the use of coherent receivers or direct detection receivers, these orthogonally polarized signals are demultiplexed at the receiver. Since compared to the direct detection, the coherent detection is more expensive, a number of efforts have been made in recent times for the development of the direct detection technique for the Polarization Division Multiplexing (PDM) signals [2]. A circularly Polarized (CP) beam, when transmitted through a PBS, produces a set of LP beams as vertical and horizontal polarizations meaning that it is more efficient than PDM for the improvement of the spectral efficiency of the fiber optic system and hence makes the information carrying capacity of the fiber double than that of PDM [3-4].

In this paper, we present a proposal to incorporate CPDM into the QPSK fiber optic communication (FOC) system with a view to quadrupling the spectral efficiency and accordingly the bandwidth of the system without altering the spectral width of the transmitter. This paper analyses the performance of a prevailing CPDM-QPSK system with direct detection affected by XPol induced crosstalk. At the output of direct detection receiver, SCNR and BER have been evaluated analytically. Considering different system parameters, a numerical estimation is carried out for the decline of the BER performance by cross-polarization. Similar estimation is carried out for power penalties suffered by cross-polarization.

This is the description of the organization of the paper. The detailed system model for CPDM-QPSK direct detection is mentioned in Section II. Theoretical analysis of the system with configuration is done in Section III by analytical evaluation of the BER and SCNR. Section IV depicts the results found from the simulation. Ultimately, Section V concludes the paper by precising the analysis.

II. System Model

The block diagram of a CPDM-QPSK transmitter is depicted in Fig. 1 where, two orthogonal and circularly polarized input lasers electric fields are separated by the Circularly Polarization Beam Splitter (CPBS) into two components, RCP and LCP. Consequently, these two components individually pass through the Polarization Beam Splitter (PBS) modules and are divided into two linearly polarized beams separately. Using the Mach Zender Modulator linearly polarized signals are QPSK Modulated. Then the RCP and LCP signals are combined using a Circularly Polarization Beam Combiner (CPBC).

The receiver shown in Fig. 2 follows direct detection method for demodulating the transmitted signal. The electric fields of signals received from transmitter section are divided into two components (RCP and LCP) by the help of a CPBS and are further split into two components by two PBSs. Each output of PBS is fed into QPSK demodulators. Hence, the original electrical signal is recovered from its transmitted data. In CPDM-QPSK we get 4 pairs of orthogonal components which eventually quadruples the transmission rate without altering the spectral width of the transmitter.

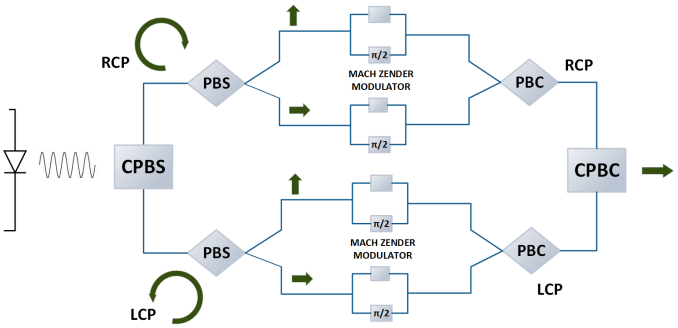

Fig. 1. CPDM-QPSK transmitter section

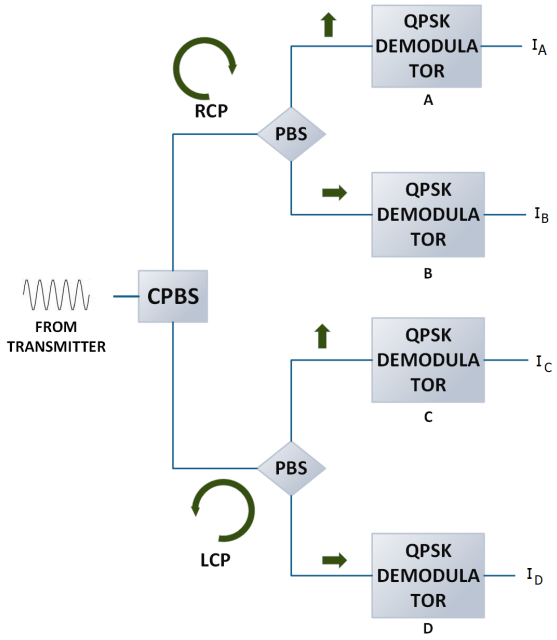

Fig. 2. CPDM-QPSK Direct Detection receiver section

III. Theoretical Analysis

The uneven rotations of the sub-channel SOPs cause misalignment of the eigenmode of PBS of the receiver which deteriorates the signals by inducing crosstalk and fading between the sub-channels.Taking $|e'_x\rangle$ and $|e'_y\rangle$ are the eigenmodes of the PBS, the sub-channel electric field E_x will be the component of the main field along e'_x. Thus [4],

$$|e'_x\rangle \langle e'_x|E|e'_x|E\rangle = \varepsilon_F E_x |e'_x\rangle + \varepsilon_X E_y |e'_x\rangle \tag{1}$$

where,

$$\varepsilon_F = \langle e_x{}'|e_x\rangle = \text{complex co-efficient of fading}$$
$$\varepsilon_X = \langle e_x{}'|e_y\rangle = \text{complex co-efficient of crosstalk}$$

The magnitude of ε_F and ε_X can be determined as [4],

$$|\varepsilon_F| = \cos(\theta/2) \text{ and } |\varepsilon_X| = \sin(\theta/2) \tag{2}$$

here, the random misalignment angle, θ satisfies the Maxwell-Boltzman pdf with mean θ_m. Thus, the pdf of θ can be written as [5],

$$p(\theta) = \frac{32}{\pi^2 {\theta_m}^3}\theta^2 \exp\left\{\left(\frac{-4\theta^2}{\pi {\theta_m}^2}\right)\right\} \tag{3}$$

The output signal at the PBS [1],

$$\begin{aligned} E_{RCP,x} &= \text{Re}[\varepsilon_F E_s e^{j\phi} + j\varepsilon_X E_s e^{j\phi}] \\ &= \varepsilon_F E_s \cos(\omega t - kz) - \varepsilon_X E_s \sin(\omega t - kz) \end{aligned} \tag{4}$$

$$\begin{aligned} E_{RCP,y} &= \text{Re}[\varepsilon_F E_s e^{j(\phi+\frac{\pi}{2})} + j\varepsilon_X E_s e^{j(\phi+\frac{\pi}{2})}] \\ &= -\varepsilon_F E_s \sin(\omega t - kz) - \varepsilon_X E_s \cos(\omega t - kz) \end{aligned} \tag{5}$$

where, $\phi = (\omega t - kz)$.
Likewise,

$$E_{LCP,x} = \varepsilon_F E_s \cos(\omega t - kz) - \varepsilon_X E_s \sin(\omega t - kz) \tag{6}$$

$$E_{LCP,y} = \varepsilon_F E_s \sin(\omega t - kz) + \varepsilon_X E_s \cos(\omega t - kz) \tag{7}$$

The PBC input is as follows,

$$\begin{aligned} E_{RCP,1} &= -(\varepsilon_X E_s \cos\phi + \varepsilon_F E_s \sin\phi) \\ &\quad + (\varepsilon_X E_s \sin\phi - \varepsilon_F E_s \cos\phi) \end{aligned} \tag{8}$$

$$\begin{aligned} E_{RCP,2} &= -(\varepsilon_X E_s \cos\phi + \varepsilon_F E_s \sin\phi) \\ &\quad - (\varepsilon_X E_s \sin\phi - \varepsilon_F E_s \cos\phi) \end{aligned} \tag{9}$$

The PBC output is,

$$\begin{aligned} E_{RCP} &= a_{even}(\varepsilon_X E_s \cos\phi + \varepsilon_F E_s \sin\phi) \\ &\quad + a_{odd}(\varepsilon_X E_s \sin\phi - \varepsilon_F E_s \cos\phi) \end{aligned} \tag{10}$$

Similarly,

$$\begin{aligned} E_{LCP} &= b_{even}(\varepsilon_X E_s \cos\phi + \varepsilon_F E_s \sin\phi) \\ &\quad + b_{odd}(\varepsilon_X E_s \sin\phi - \varepsilon_F E_s \cos\phi) \end{aligned} \tag{11}$$

For direct detection, the received signal from the transmitter,

$$r_A = s\exp(-\alpha d) \tag{12}$$

where, $s = E_{RCP} + E_{LCP}$
α = attenuation constant, d = distance from the transmitter to receiver.

The output photo-current from the QPSK demodulator,

$$\begin{aligned} I_A &= R_d|r_A|^2 \\ &= R_d|a_{odd}(\varepsilon_X E_s \sin\phi - \varepsilon_F E_s \cos\phi)|^2 \\ &= R_d(\varepsilon_X^2 P_s + \varepsilon_F^2 P_s) \\ &= I_{sig,A} + I_{xtalk,A} \end{aligned} \tag{13}$$

where, the responsivity of photo-diode is,

$$R_d = \frac{e\eta}{h\nu}$$

where,

η = quantum efficiency, ν = operating frequency

e = electronic charge, h = Plank's constant

$$P_s = \frac{E_s^2}{2},\ P_{LO} = \frac{E_{LO}^2}{2}$$

where, the singal and the crosstalk currents are,

$$I_{sig,A} = R_d \varepsilon_F^2 P_s$$
$$I_{xtalk,A} = R_d \varepsilon_X^2 P_s$$

So, combining XPol-induced crosstalk for a chosen BER and mean misalignment angle θ_m, the conditional $SCNR(\theta)$ can be calculated by,

$$SCNR(\theta) = \frac{|I_{sig,A}|^2}{|I_{xtalk,A}|^2 + \sigma_{noise}^2} \tag{14}$$

where, the total noise power,

$$\sigma^2{}_{noise} = \sigma^2{}_{thermal} + \sigma^2{}_{shot}$$

where , $\sigma^2{}_{thermal} = 4kTB/R_L$ and $\sigma^2{}_{shot} = \sqrt{2}eBI_{sig,A}$

Using the following formulas we can calculate both the $BER(\theta)$ and the average BER,

$$BER(\theta) = \frac{1}{2}\text{erfc}(\sqrt{\frac{SCNR(\theta)}{2}}) \tag{15}$$

The average BER is,

$$\text{BER} = \int_0^{\pi/2} BER(\theta) p(\theta) d\theta \tag{16}$$

IV. Results & Discussions

Subsequent to the analytical obtainment given in previous section, Section IV elucidates the simulation results of SCNR(θ), BER(θ) and power penalty influenced by cross-polarization induced crosstalk. Table I displays the parameters with appropriate values for this simulation.

TABLE I
Simulation Parameters and their Standard Values

Parameters	Value
Charge of electron , e	1.6021 × 10^{-19} Coul
Responsivity , R_d	0.85
Temperature , T	300K
Boltzmann Constant , k	1.38065 × 10^{-23} J/K
Load Resistance , R_L	25 Ω

Fig. 3 delineates the plots of SCNR (with and without the XPol-induced crosstalk) vs misalignment angle for different values of optical received signal power of -20 dBm, -15 dBm and -10 dBm. Due to XPol-induced crosstalk there is a significant drop in the performance of SCNR as the SCNR decreases with the rise of misalignment angles which is clear from the equation (14). When there is no crosstalk, SCNR is higher and it rises with the rise in optical received signal power, also supported by the equation (14). The maximum SCNR is found to be 33.2 dB when there is no cross-polarization at a received signal power of -10 dBm.

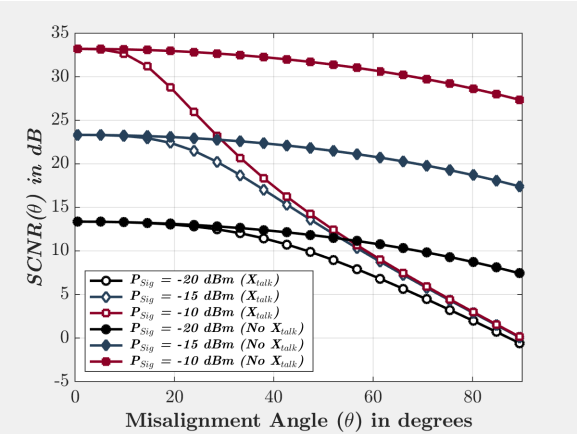

Fig. 3. SCNR (with and without crosstalk) vs misalignment angle for different received signal power.

The increment of BER with the rise of mean misalignment angles is shown in Fig. 4. When the received signal power is higher it causes lower BER and at a fixed received signal power BER rises with rise in crosstalk that is misalignment angles. It is evident in the graph that at a given signal power of -6 dBm , the BER rises from 10^{-20} to almost 10^{-1} for incrementing mean misalignment angles from 9 to 45 degrees. So, it is evident that increasing misalignment angle also gradually increases the BER for an adjusted signal power since misalignment angle increments Xtalk power. The degrading performance of BER is caused by the emersion in crosstalk power which satisfies Fig. 4 as well as the equations (14) and (15).

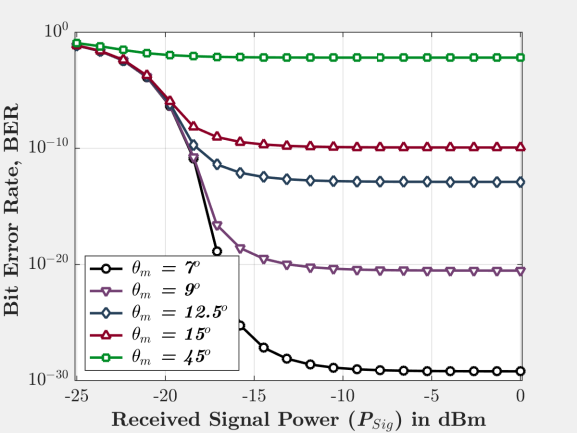

Fig. 4. BER vs Received signal power for different misalignment angles.

Fig. 5 signifies the loss of SCNR as a function of misalignment angle for multiple values of signal power. We see that the losses of SCNR is extra at greater values of received signal power and higher values of misalignment angles. The

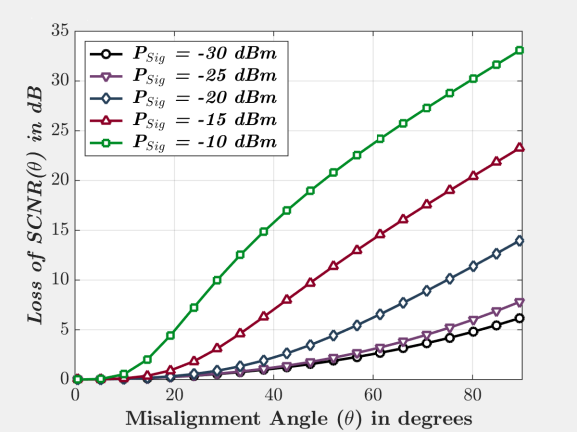

Fig. 5. Loss of SCNR vs misalignment angle for multiple values of signal powers.

loss of SCNR is 8.66 dB from 9.99 dB to 1.33 dB when the received signal power is lessened from -10 dBm to -30 dBm at a misalignment angle of 30 degree.

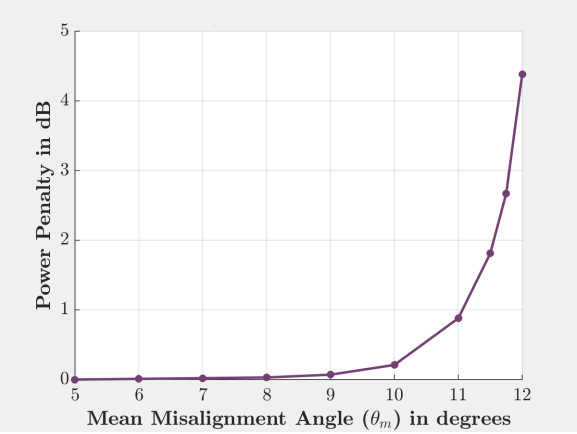

Fig. 6. Power penalty vs mean misalignment angle at BER 10^{-9}.

Fig. 6 represents the power penalty vs mean misalignment angles at a fixed BER of 10^{-9}. This plot elucidates the result of XPol-induced crosstalk which suffers power penalty. According to the estimation, the system undergoes power penalty of 0.18, 0.92 and 4.44 dB for the mean misalignment angles of 10, 11 and 12 degrees respectively at a BER of 10^{-9}. The given analysis makes it explicit that, as the misalignment angle augments, the BER performance declines for the interference of crosstalk into the main signal.

V. Conclusion

This paper introduces CPDM-QPSK for direct detection FOC system intending to quadruple the spectral efficiency. According to the analysis of SCNR, BER and power penalty, it is observed that the interference of crosstalk into main signal weakens the system resulting in the decline of BER and SCNR performance. Therefore, the system suffers power penalty for different misalignment angles. This eventually lessens the receiver sensitivity to acquire a BER of 10^{-9}. However, using this method the spectral bandwidth can be improved to a great extant. The current approach stands on the theoretical and mathematical analysis of circular polarization in light which can provide compelling advantages in the future of faster FOC system.

***Abstract*—An UWB Vivaldi antenna is proposed for cancer detection and treatment. The antenna operates at the resonant frequency of 4.76 GHz within the bandwidth of 4.63 GHz (3.13 GHz-7.76 GHz) in free space. In addition, the antenna possesses a high radiation efficiency of 81.34% and a gain of 5.81 dB in free space condition. The overall dimension of the proposed antenna is 110.46 x 96.77 x 1.67 mm^3. The antenna is simulated with 1.6 mm thick FR-4 dielectric substrate since it is cost-effective and easily available. Furthermore, a six-layer biological tissue model comprising of skin, fat, outer cortical bone, cancellous bone, inner cortical bone, and muscle with a tumor of 10 mm radius is modeled to assess antenna performance for cancer detection and treatment. In simulation, a specific gap of 2.5 mm is maintained between the proposed antenna and the proposed phantom model in order to avoid skin burn and other side-effects. Cancerous cells in tumor are detected and killed because of higher SAR value of the cancerous tissue than the normal healthy tissue.**

Keywords—UWB Vivaldi antenna, phantom model, SAR, cancer detection, cancer treatment.

I. INTRODUCTION

The underlying concept of cancer detection and treatment is to diagnose and cure cancerous cells ensuring minimum cumulative side-effects of the nearby healthy tissues. The malignant tumor is responsible for generating cancer which is the second leading cause of death [1]. Antenna can be used as the basic element of cancer detection and treatment. For the detection of cancer, microwave imaging is one of the most prominent methods where the tumor shows electrical properties that are substantially different from those of healthy tissues. One leading feature of microwave imaging antenna is that the antenna must have ultra-wideband (UWB) characteristics to enhance the resolution of the image [2]. Cancer treatment can also be performed by applying high doses of antenna radiation beam on the detected tumor region. This process is called radiotherapy. It is executed very carefully so that the adjacent healthy tissues do not get damaged along with the cancerous tissues. In recent years, many antennas including Vivaldi antenna, Dipole antenna, Monopole antenna, Bow-tie antenna, Pyramidal horn antenna, Microstrip patch antenna, Log periodic antenna, and Spiral antenna have been designed for microwave imaging and radiotherapy applications [3].

The Vivaldi antenna is one of the most popular directive antennas which is widely used for commercial UWB applications like microwave imaging and radiotherapy. This antenna provides significant advantages such as high efficiency, high gain, wide bandwidth, simple geometry and so on. In a recent paper, Alzabidi *et al.* [2] proposed an optimum UWB Vivaldi antenna for tumor detection. The antenna had an antipodal configuration and it achieved better performance for an overall dimension of 329.25 x 153 x 1.6 mm^3. The bandwidth of the antenna was nearly 0.8 GHz after simulating with phantom model. In another paper, Alsulaiman *et al.* [4] proposed an ultra-wideband balanced antipodal Vivaldi antenna for hyperthermia treatment. The overall volume of the antenna was 82 x 92 x 1.6 mm^3. After simulating this antenna with phantom model, a bandwidth of 3.7 GHz was obtained. In this paper, the aim is to design an UWB Vivaldi antenna assuring improved performance (e.g., bandwidth) than the existing ones for cancer detection and treatment.

In cancer detection and treatment, biocompatibility analysis for human safety is vital. One of the biocompatibility analysis factors is specific absorption rate (SAR). The term SAR refers to a parameter used to measure the power absorbed per mass of body tissue [5]. This calculation is performed as a post-processing step after simulation. According to IEEE C95.3 method, a cube is grown around the specific point until it contains the required mass of body tissue corresponding to a reference power. Tissue with malignant tumor shows higher value of SAR than that of normal healthy tissue [2]. This variation of SAR gives an indication of the presence of tumor and an indication of absorption of power in tumor. The value of SAR can be calculated by using a biological tissue model around the antenna.

The organization of this paper is as follows: Section II presents the theory of Vivaldi antenna, the design equations and configuration of the proposed Vivaldi antenna. Section III illustrates the antenna performance in free space and with the proposed six-layer biological tissue model. Ultimately, discussion and conclusion are provided in Section IV and Section V respectively.

II. VIVALDI ANTENNA DESIGN

A. Theory of Vivaldi Antenna

The basic Vivaldi antenna has an exponentially tapered slot profile. Primarily, the antenna consists of a dielectric substrate and a slot-line for feeding purpose. The basic configuration of this antenna is shown in Fig. 1. The antenna is also known as travelling wave antenna which can be categorized into propagating section and radiating section [6]. The slot width indicates the separation between the conductors. In the propagating section, the slot width is less than one-half of free space wavelength ($\lambda_0/2$) while the opposite situation occurs in the radiating section. Therefore, the bond between the conductors and the curved portion of antenna is stronger in the propagating section than that in the radiating section. The Vivaldi antenna is most fruitful

with slot-line feeding because of design flexibility. In this scheme, a transition is designed to couple signals to the slot-line from the transmitter or receiver. The transition causes low loss over a wide range of frequency so that it does not limit the operating bandwidth.

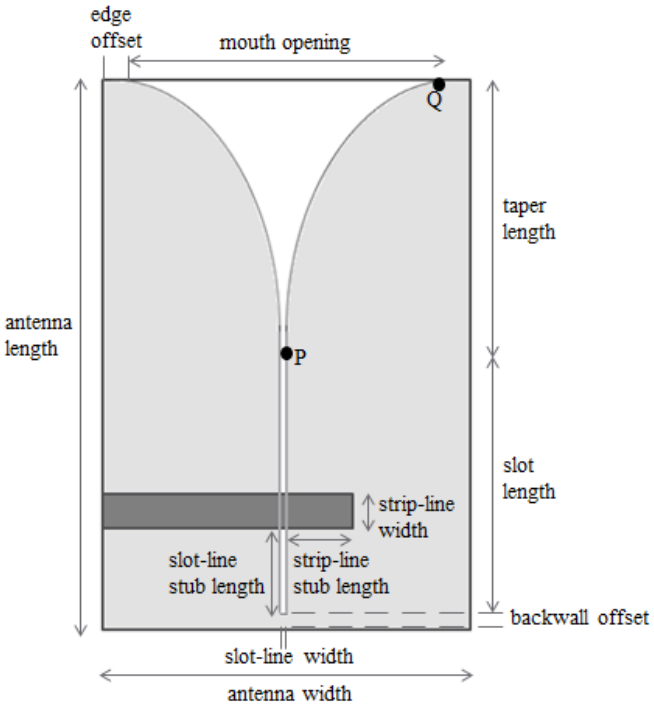

Fig. 1. Basic configuration of Vivaldi antenna.

(i) Substrate width (*subw*): In order to accomplish the desired radiation performance, the substrate width (*subw*) should be greater than one-half wavelength at the lowest frequency of operation (λ_{min}) [6].

$$subw > \frac{\lambda_{min}}{2} \tag{1}$$

(ii) Taper length (*TL*): In this design, the taper length (*TL*) is equal to the substrate width (*subw*) as given below:

$$TL = subw \tag{2}$$

(iii) Taper rate (*r*): The taper rate (*r*) can be defined by an exponential equation as [7],

$$Y = C_1 e^{-rx} + C_2 \tag{3}$$

where, $C_1 = \frac{y_2 - y_1}{e^{rx_2} - e^{rx_1}}$ and $C_2 = \frac{e^{rx_2} y_1 - e^{rx_1} y_2}{e^{rx_2} - e^{rx_1}}$

(iv) Strip-line width (*MW*): Depending on the dimensions of the transmission line, the characteristic impedance Z_0 can be calculated as [7]:

$$Z_0 = \frac{60}{\varepsilon_r} ln\left(\frac{8h}{MW} + \frac{MW}{4h}\right) \tag{4}$$

where, *MW* = strip-line width and *h* = substrate thickness

(v) Slot-line width (*2S*): It indicates the separation between the slot-line conductors before the tapered section [6]. This parameter should be determined carefully in order to get the desired return loss response.

(vi) Slot-line stub length (*QWS*): The length of slot-line stub is determined by this parameter [6]. The stub length should be open circuited by means of a short circuited quarter wavelength stub in order to improve field coupling.

(vii) Strip-line stub length (*QWM*): The strip-line prolongs a finite length and ends to slot-line transition [6].

(viii) Slot length (*SL*): In this design, the slot length (*SL*) is calculated by summing stripline width (*MW*) and slot-line stub length (*QWS*) as follows:

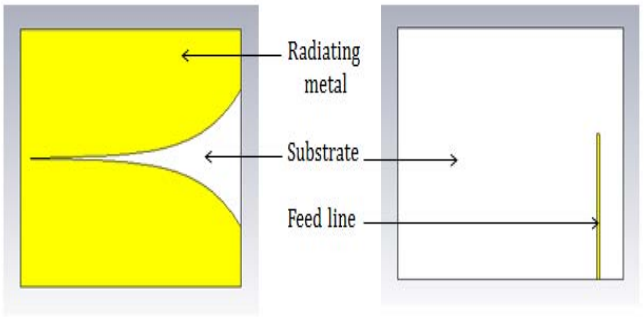
$$SL = MW + QWS \tag{5}$$

(ix) Microstrip length (*ML*): In this design, the microstrip length (*ML*) is obtained by summing quarter wave microstrip (*QWM*) i.e., strip-line stub length, half of slot width (*s*) and half of substrate width (*subw*) as follows:

$$ML = QWM + s + subw/2 \tag{6}$$

(x) Backwall offset (*ext*): The backwall offset (*ext*) refers to the extra metallization that is implanted at the origin of the slot-line [6]. This parameter should be optimized in order to prevent any deterioration in return loss response.

(xi) Antenna length (*L*): Antenna length (*L*) is the summation of taper length (*TL*), strip-line width (*MW*), strip-line stub length (*QWS*) and backwall offset (*ext*). Antenna length should be greater than a free space wavelength at the lowest frequency of operation (λ_{min}) to ensure an improved gain and beamwidth performance [6]. Mathematically, it is expressed as follows:



$$L = TL + MW + QWS + ext \tag{7}$$

(xii) Antenna width (*W*): In this design, antenna width (*W*) is equal to the substrate width (*subw*) as given below:

$$W = subw \tag{8}$$

B. Antenna Configuration

The configuration of the proposed Vivaldi antenna is shown in Fig. 2. The design parameters of this antenna are listed in Table I which have been calculated from the design equations given in Sub-section A. In this antenna design, the annealed copper with a thickness of 0.035 mm is used as the metal or radiating element and the FR-4 lossy dielectric material with a thickness of 1.6 mm is used as the substrate. The microstrip to slot-line feed is used as the feeding technique to obtain the resonance at the selected frequency of 4.76 GHz. The total volume of the antenna is 110.46 x 96.77 x 1.67 mm^3. The top metallic part provides the current flow path. The feedline is located at 0.035 mm distance from the substrate at the bottom part. The iterative simulation method is used to match the antenna impedance with the feeder impedance of 50 Ω.

(a) (b)

Fig. 2. Configuration of the proposed Vivaldi antenna (a) Top view (b) Bottom view.

TABLE I. DESIGN PARAMETERS OF THE PROPOSED VIVALDI ANTENNA

Design parameter	Symbol	Value (mm)
Substrate thickness	*h*	1.6
Substrate width	*subw*	96.77
Taper length	*TL*	96.77
Taper rate	*r*	0.05
Stripline width	*MW*	1.3068

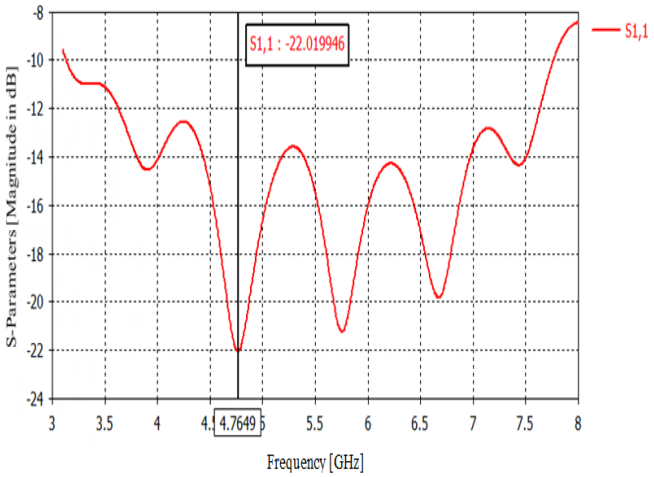
III. ANTENNA PERFORMANCE

A. In Free Space

The design and simulation of the proposed antenna is done in the commercial software package of CST Studio Suite 2015. After simulating the antenna in free space, the following results are obtained:

Fig. 3 shows the S_{11} parameter of the proposed Vivaldi antenna in free space where the antenna resonates at 4.76 GHz with a return loss of -22.019946 dB. The simulated bandwidth is 4.63 GHz (3.13 GHz-7.76 GHz) below -10 dB return loss which meets the need of ultra-wideband. Such a bandwidth is achieved by optimizing the design parameters of the antenna which is particular in the minimization of taper rate (*r*). The radiation efficiency of the proposed Vivaldi antenna at 4.76 GHz in free space is -0.8969583 dB, i.e., 81.34 % because of a good impedance matching.



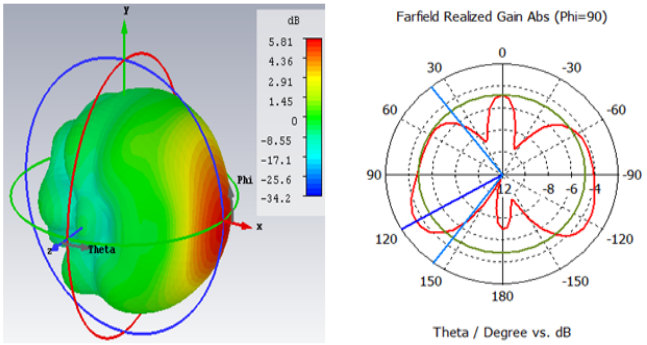


Fig. 3. Simulated return loss response of the proposed Vivaldi antenna in free space.

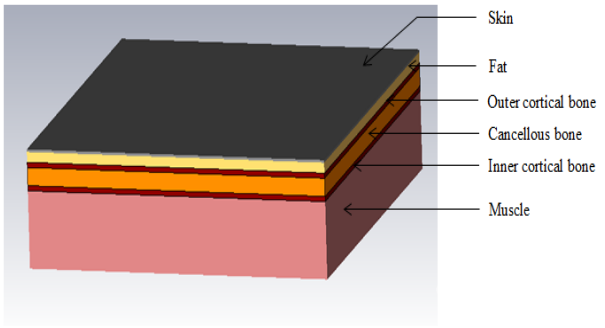
Fig. 4 (a) shows the 3-D gain pattern and Fig. 4 (b) presents the 2-D gain pattern (recorded at $\theta = 0^0$, $\varphi = 90^0$) at 4.76 GHz of the proposed Vivaldi antenna in free space. From Fig. 4 (a), it is obvious that the maximum gain is 5.81 dB and the maximum radiation is along the central axis of the tapered slot. From Fig. 4 (b), it is apparent that the main lobe magnitude is -3.47 dB along the direction of -122^0. Besides, the 3-dB beamwidth is 106.9^0 and the side lobe level has a small value of -1.3 dB. These characteristics reveal that the antenna exhibits end-fire radiation pattern as required for cancer detection and treatment.



(a) (b)

B. Proposed Biological Tissue Model

A six-layer biological tissue model with rectangular shape consisting of skin, fat, outer cortical bone, cancellous bone, inner cortical bone and muscle is modeled as shown in Fig. 5 (a). A tumor with spherical shape is inserted in the muscle tissue layer as shown in Fig. 5 (b). The model is designed using the dielectric properties of tissue as indicated in Table II at the resonant frequency of 4.76 GHz. The thicknesses of the tissue layers and the radius of the tumor are relevant to human body. In order to assess the performance of the antenna with the six-layer biological tissue model, the antenna is pulled on the phantom maintaining a distance of 2.5 mm from skin [8] to avoid skin burn.

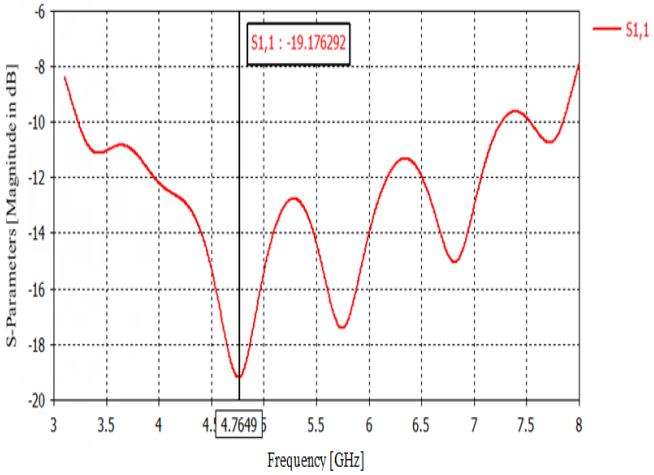
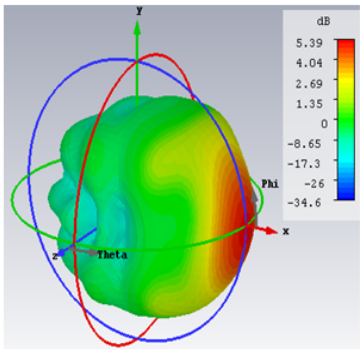
TABLE II. DIMENSIONS AND DIELECTRIC PROPERTIES OF SIX-LAYER BIOLOGICAL TISSUE MODEL AT 4.76 GHZ [9]-[10]

Layer name	Volume (mm^3)	Dielectric properties			
		Relative permitivity	Loss tangent	Conductivity (S/m)	Mass density (kg/m^3)
Skin	200x200x1	35.969	0.3021	2.8774	1100
Fat	200x200x4	5.0518	0.17006	0.2275	910
Outer cortical bone	200x200x2	10.154	0.33665	0.9052	1900
Cancellous bone	200x200x7	16.257	0.39757	1.7115	570
Inner cortical bone	200x200x2	10.154	0.33665	0.9052	1900
Muscle	200x200x30	49.852	0.28673	3.7851	1041
Tumor (10 mm radius)	4188.79	50.821	0.26665	4	1041

C. *Antenna Performance with Proposed Biological Tissue Model*

The antenna is simulated with biological tissue model. The proposed Vivaldi antenna resonates at 6 GHz with phantom and tumor which is different from the free space response. Hence antenna size is modified to resonate the antenna at 4.76 GHz like in free space. For this purpose, the dimension of the antenna is merely changed, i.e., the substrate width (*subw*) is increased from 96.77 mm to 99.5 mm and the taper rate (*r*) is reduced from 0.05 to 0.04. Other parameters are kept unchanged. Then the simulated resonant frequency is obtained at 4.76 GHz with a return loss of -19.176292 dB as shown in Fig. 6. Here the bandwidth of 4 GHz (3.24 GHz-7.24 GHz) is found below -10 dB return loss which is slightly lower than 4.63 GHz as obtained in free space. The other performance parameters described below are also simulated with this changed dimension of the antenna.





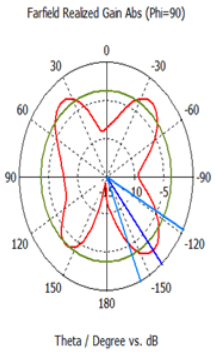


Fig. 6. Simulated return loss response of the proposed Vivaldi antenna with phantom and tumor.

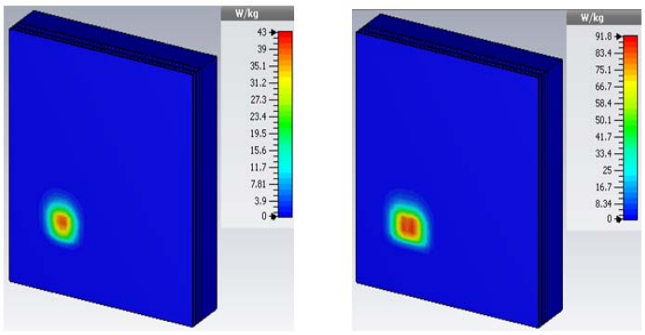
The radiation efficiency of the proposed Vivaldi antenna with phantom and tumor at 4.76 GHz is -1.8206393 dB, i.e., 65.76%. Fig. 7 (a) shows the 3-D gain pattern and Fig. 7 (b) shows the 2-D gain pattern (recorded at $\theta = 0^0$, $\varphi = 90^0$) at 4.76 GHz of the proposed Vivaldi antenna with phantom and tumor. From Fig. 7 (a), it is obvious that the maximum gain is 5.39 dB. It is evident from Fig. 7 (b) that the main lobe magnitude is -2.43 dB along the direction of -140^0. Besides, the 3-dB beamwidth is 39.2^0 and the side lobe level is -1.2 dB.



(a)

(b)

Fig. 7. Simulated far-field gain pattern of the proposed Vivaldi antenna with phantom and tumor (a) 3-D view (b) 2-D view.

The SAR distribution of the proposed Vivaldi antenna (i) with phantom (ii) with phantom and tumor is simulated. Fig. 8 (a) shows 10 g average SAR determined at 4.76 GHz and at operating power of 0.5 W. From Fig. 8 (a), it is obvious that the maximum SAR is 43 W/kg which is less than 91.8 W/kg obtained in Fig. 8 (b). This dissimilation is an indication of the presence of tumor and absorption of power in it. The identified tumor is gradually killed as a consequence of absorbing the massive radiation beam of antenna. In this procedure, the detection and treatment of cancer are performed in a comprehensive manner.

(a) (b)

Fig. 8. Simulated SAR distribution of the proposed Vivaldi antenna (a) with phantom (b) with phantom and tumor.

IV. DISCUSSION

The bandwidth (i.e., 4 GHz) of the proposed Vivaldi antenna with biological tissue model is much higher than the bandwidth (i.e., ≈ 0.8 GHz) of that proposed by Alzabidi *et al.* [2] and the bandwidth (i.e., 3.7 GHz) of that proposed by Alsulaiman *et al.* [4]. In addition, the proposed Vivaldi antenna has reduced physical dimension (i.e., 110.46 x 96.77 x 1.67 mm^3) compared to the physical dimension (i.e., 329.25 x 153 x 1.6 mm^3) of that proposed by Alzabidi *et al.* [2].

V. CONCLUSION

In this paper, an UWB Vivaldi antenna is proposed for cancer detection and treatment. Moreover, a six-layer biological tissue model consisting of skin, fat, outer cortical bone, cancellous bone, inner cortical bone, and muscle with a tumor of 10 mm radius is modeled. From the simulation results, it is obvious that the proposed structure has better performance than the existing ones particularly in terms of bandwidth and volume. Also it achieves a high gain and high radiation efficiency. Cancer detection and treatment are assured with the value of SAR. The cancerous tissue exhibits higher SAR value than normal tissue. It can be concluded that the proposed UWB Vivaldi antenna can enhance the resolution of microwave image for cancer detection. This antenna can be used for cancer treatment as well by means of emitting high radiation beam on cancerous cells in tumor. Thus it can provide a bright future in the field of cancer detection and treatment.

***Abstract*—In this paper, a new kind of hybrid-core porous hexagonal microstructure fiber is presented for different chemical identification by using terahertz signal. In order to analyze the guiding characteristics, finite element method (FEM) based Comsol *V*5.3a software is utilized. By filling the core air holes with aqueous analytes (Benzene and Ethanol) and tuning various designing parameters, maximum relative sensitivity of 79.2% and 78.9% is achieved at 1.5 THz for benzene and ethanol respectively. Along with the high sensitivity the proposed fiber offers very low confinement loss of 7.4×10^{-11} cm^{-1} and low bending loss of 4.9×10^{-36} cm^{-1} at optimal condition for Benzene. This proposed fiber is very easy to realize and can be easily fabricated by using the recent popular fabrication technique. It seems that, the excellent characteristics will made the proposed fiber a good candidate in different chemical identification applications.**

Keywords—relative sensitivity, porous core, terahertz, bending loss, confinement loss.

I. INTRODUCTION

Very recently a particular narrow frequency band of electromagnetic spectrum have become a hot topic to the researchers. This frequency band is known as terahertz radiation band and the frequency range of the promising band is 0.1 to 10 THz [1]. The main reason behind the popularity of this narrow frequency band is that this terahertz signal can be effectively used in various applications including communication, security, imaging, spectroscopy, cancer cell detection [2-7] etc. In recent years, terahertz signal is effectively used in different chemical identification such as benzene, ethanol, formalin etc. [8-10]. In case of photonic crystal fiber (PCF), air holes are arranged in different geometric orientation to maintain dielectric condition. According to light guiding mechanism the PCF can be classified into two different category and they are photonic bandgap (PBG) and indexed guiding PCF. When the effective refractive index of the core section is higher than the cladding then the light will be forwarded by using total internal reflection mechanism. If the cladding's refractive index is lower than that of core, then the guiding mechanism will be PBG and this kind of PCF is known as porous core photonic crystal fiber (PC-PCF).

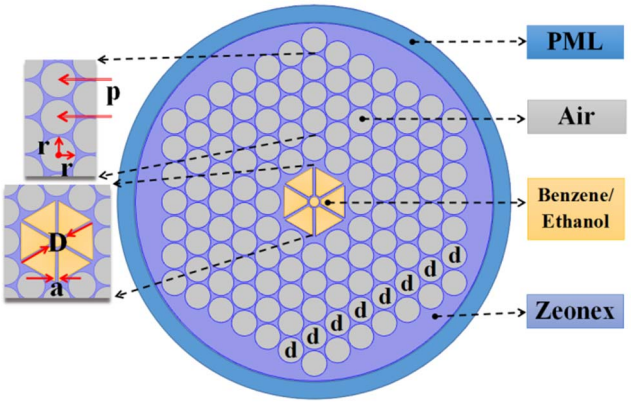
Highly sensitive chemical sensor is essential to identify toxic and flammable chemicals in different industrial applications [11]. That's why the optoelectronics researchers have proposed different types of chemical sensors for different chemical detection. In 2016, Asaduzzaman *et al*. proposed a hybrid core PCF where elliptical shaped air holes are introduced in the core region to create asymmetry in the core [12]. This proposed fiber exhibited low birefringence of 0.0015, relative sensitivity of 49.71% for ethanol, low confinement loss of 2.75×10^{-10} dB/m at optimum geometric condition. A hexagonal lattice chemical sensor with six elliptical air holes in core was proposed by Arif et al. in 2017, which offered maximum sensitivity of 53.35%, low birefringence of 0.0028, low confinement loss of 1.6×10^{-10} dB/m simultaneously at 1.33 μm operating wavelength. After that, Arif *et al*. proposed another PCF based chemical sensor which offered better sensitivity than the previous one [13]. Their proposed hexagonal shaped sensor offered high relative sensitivity of 59% and low confinement loss in the order of 10^{-11} dB/m for optimum designing parameters. Paul et al. proposed a folded shaped silica based porous core photonic crystal fiber [14], which offered very high relative sensitivity of 69% and low confinement loss of 5×10^{-11} dB/cm for benzene at 1.33 μm operating wavelength.

In this paper, we propose a hexagonal type hybrid core microstructure fiber for benzene and ethanol detection by using terahertz signal. The proposed chemical sensor offers very high sensitivity of 78.07%, low confinement loss of 7.4×10^{-11} cm^{-1}, large effective area of 0.94×10^{5} μm^2, very low bending loss of 4.9×10^{-36} cm^{-1} simultaneously at 1.5 THz for optimum geometric condition. The proposed fiber can be fabricated by using Extrusion technique. So, we hope these excellent characteristics will make the chemical sensor a handy one in various sensing applications.

II. GEOMERTY OF PROPOSED SENSOR

The cross-sectional view of the proposed porous-core PCF terahertz sensor with its enlarged version of core and cladding is shown in Fig. 1. Finite element method (FEM) based commercially available software COMSOL Multiphysics v5.3a is used to design the sensor. In cladding region hexagonal type lattice is introduced by using circular shaped air holes whose radius and diameter are denoted by **r** and **d** respectively. To facilitate the fabrication simplicity, sufficient distance between the air holes of the cladding is ensured and the distance between two adjacent air hole in cladding is defined as **p** and the strut thickness of the core is ***a***. The core region consists of a single circular air hole and six triangular air holes. A little edge of the six triangular air holes are detruncated to avoid overlapping. The total diameter of the core is defined as ***D*** which is related to ***r*** i.e. $\boldsymbol{D} = 2.5\boldsymbol{r}$. The chemicals which will be subjected to test will be placed in the core air hole and the light signal will be introduced through the fiber. In the numerical analysis

benzene (n= 1.366) and ethanol (n= 1.354) are used as test analyte and the guiding characteristics are checked. A perfectly matched layer (PML) absorbing boundary which thickness is 10% of the fiber radius is given at the outer part of the cladding because the PML boundary condition itself act as an anti-reflecting layer that absorbs outgoing waves of the PCF. Though there are several number of polymer materials that can be used as a bulk material for designing a sensor, for this proposed sensor Zeonex is chosen as the bulk material. This is because of it's number of useful optical properties such as constant index of refraction of 1.53 in terahertz range, low absorption loss of 0.2 cm^{-1}, high glass transition temperature, negligible water absorption, high biocompatibility and excellent chemical resistance even at elevated temperatures [17].



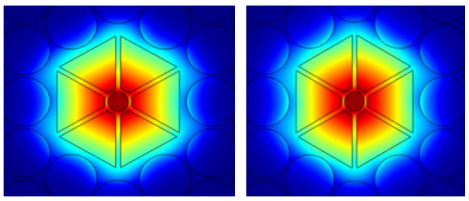


Fig. 1. Cross-sectional view of the proposed hybrid-core microstructure fiber.

III. Simulation Results and Discussion

To analyze the guiding properties full vectorial finite element method with Perfectly Matched Layer (PML) boundary condition is adopted with a FEM based software Comsol *V5.3a*. The mode field distribution of the proposed chemical sensor for benzene and ethanol at 1.5 THz is reported in Fig. 2 which indicates that the light signal is tightly confined through the central portion of the core. The following figure also ensures better interaction between the light signal and the test analyte which is essential for chemical detection.

(a) (b)

Fig. 2. Power flow distribution of the proposed hybrid-core fiber at 1.5 THz when core diameter is 170 µm for (a) benzene and (b) ethanol.

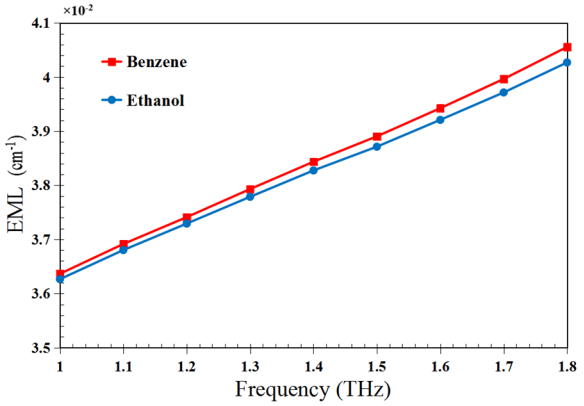

Fig. 3. Effective material loss of the proposed hybrid-core microstructure fiber as a function of frequency for D= 170 µm.

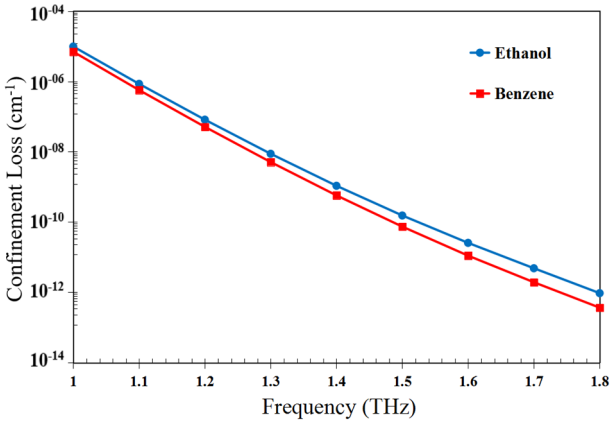

Fig. 4. Confinement loss of the proposed sensor for different operating frequencies at optimum core diameter.

At first, two types of losses will be investigated for the proposed chemical sensor and they are the effective material loss (EML) and the confinement loss. The term EML indicates the amount of light energy captured by the background material of the proposed PC-PCF. This loss can be evaluated by using the following mathematical expression [1],

$$\alpha_{eff} = \frac{\left(\varepsilon_0 / \mu_0\right)^{1/2} \int_{A_{mat}} n\,\alpha_{mat} |\mathrm{E}|^2 dA}{2\int_{All} S_z dA} \quad (1)$$

where ε_0 is for the permittivity of free space, μ_0 for the permeability of vacuum, n is the effective refractive index of the background material, E is the modal electric field, α_{mat} is the bulk material absorption loss and S_z is the z-component of the Poynting vector. The EML of the proposed chemical sensor for different operating frequency is reported in Fig. 3 for 170 µm core diameter. The reason behind the selection of particular core diameter will be reported in the further discussions. The following figure informs that the effective material loss rises with the increase of operating frequency. The physics behind that is the higher frequency electromagnetic signal always wants to propagate through the higher indexed zone. As the refractive index of Zeonex is higher than the analytes so the light of higher frequencies tries to travel through solid material than aqueous analytes. The EML of that proposed fiber are 0.0389 cm^{-1} 0.0387 cm^{-1} at 1.5 THz for benzene and ethanol respectively.

During the propagation of light signal through the core, a fraction of total light travels through the cladding air holes near the core and the air holes consume some of the light

energy. This type of loss is called confinement loss and this can be calculated by using the following expression [12],

$$\alpha_{CL} = 8.686 \times \frac{2\pi f}{c} \mathrm{Im}(n_{eff}) \quad (2)$$

where, c is the speed of the light in free space, f is for the frequency of the light and Im(n_{eff}) is the imaginary part of the refractive index of the guided mode. The confinement loss characteristics of the proposed PC-PCF is reported in Fig. 4 which shows that the variation of loss is inversely related with the frequency variation. This happens because higher frequency light travels through the core and the loss reduces. At D= 170 µm core diameter the confinement loss is 7.4×10^{-11} cm^{-1} which is comparable with [12-15].

Fig. 5 represents the EML and confinement loss of the proposed chemical sensor for different core diameter at 1.5 THz to determine the optimum core diameter. From the reported figure we can see that the EML and confinement loss intersects at 170 µm core diameter. That's why we choose 170 µm as optimum core diameter for the proposed chemical sensor. At optimum condition the numerical values of geometric parameters are **a**= 6 µm, **D**= 170 µm, **r**= 68 µm.

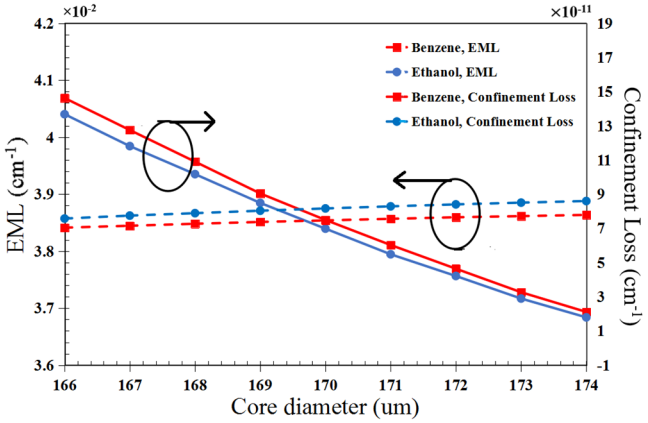

Fig. 5. EML and Confinement loss of the proposed sensor as a function of core diameter at 1.5 THz.

Now, the relative sensitivity of the proposed PC-PCF will be analyzed which is the most important characteristics of a sensor. The term relative sensitivity indicates the interaction between the electromagnetic signal and the analytes. The relative sensitivity of a sensor can be calculated by using the following equation [14],

$$r = \frac{n_r}{n_{eff}} \times P\,\% \quad (3)$$

where r is the relative sensitivity, n_r is the refractive index of the chemical to be sensed, n_{eff} is the effective refractive index of the guided mode and P is the power fraction of the guided mode. The power fraction indicates the amount of total light signal propagates through the core region. The power fraction can be calculated from the following equation [13],

$$P = \frac{\int_{sample} R_e(E_x H_y - E_y H_x)dxdy}{\int_{total} R_e(E_x H_y - E_y H_x)dxdy} \times 100 \quad (4)$$

where E_x, E_y and H_x, H_y are the transverse electric field and magnetic field of the guided light respectively. The integration of the numerator and denominator in Eqn. 4 are done for the liquid to be sensed in the core region and total area of the sensor respectively. The relative sensitivity of the hybrid core PCF as a function of frequency for benzene and ethanol are reported in Fig. 6 and Fig. 7 respectively for different geometric conditions. The relative sensitivity of the proposed sensor for both benzene and ethanol at optimum and optimum ± 2% condition is reported in the following figures. For optimum ± 2% condition all the geometric parameters (except PML thickness) are varied at the same percentage from optimum condition. From the following figure we can see that the relative sensitivity increases with the increase of operating frequency from 1 to 1.5 THz and after that the sensitivity decreases with the increase of frequency. So that 1.5 THz is considered as the optimum operating frequency for the proposed fiber. Both figure shows that the relative sensitivity is higher for optimum + 2% condition but the increased dimension of all air holes will create fabrication more complicated. The following graphical representations show that the relative sensitivity of the proposed sensor are 79.2% and 78.9% at 1.5 THz for benzene and ethanol which is better than the previous reported works in [12-15].

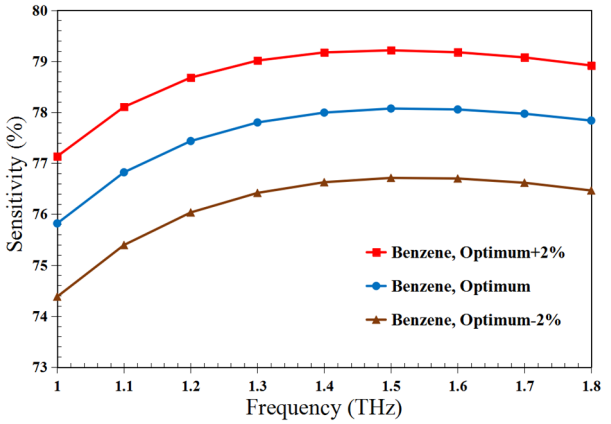

Fig. 6. Relative sensitivity of the proposed sensor at different operating frequencies for benzene at different geometric parameter.

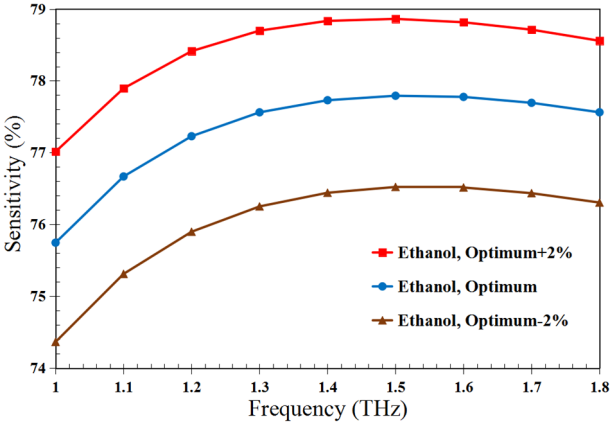

Fig. 7. Relative sensitivity of the proposed sensor at different operating frequencies for ethanol at different geometric parameter.

Now, another kind of loss of the proposed chemical sensor will be discussed which is important for the practical implementation of the sensor. During some practical applications of the fiber, it is required to bent and at the bended region a fraction of light come out from the central region. This type of loss is called bending loss and this can be calculated by using the following equation [5],

$$\alpha_{BL} = \frac{1}{8}\sqrt{\frac{2\pi}{3}}\frac{1}{A_{eff}}\frac{1}{\beta}F\left[\frac{2}{3}R\frac{\left(\beta^2-\beta_{cl}^2\right)^{3/2}}{\beta^2}\right] \quad (5)$$

where R is the bending radius, $F(x) = x^{-1/2}e^{-x}$,the propagation constant β and β_{cl} are defined as $\beta = 2\pi n_{co}/\lambda$ and $\beta_{cl} = 2\pi n_{cl}/\lambda$ respectively and A_{eff} is the effective area of guided mode light. The effective area can be can be evaluated by using the following equation [5],

$$A_{eff} = \frac{\left[\int I(r)rdr\right]^2}{\left[\int I^2(r)dr\right]^2} \quad (6)$$

where, $I(r) = |E_t|^2$ is the electric field of the fundamental guided mode. The effective area of the proposed chemical sensor at optimal designing parameter is reported in Fig. 8. The following figure reported that the effective area decreases with the increase of operating frequency because the light shows better confinement at higher frequencies and the effective area decreases. Fig. 9 shows the bending loss of the proposed sensor for R=1cm and R=2 cm at different operating frequencies for both benzene and ethanol. From the previously reported figure we can see that the bending loss of the proposed sensor is 4.9×10^{-36} cm^{-1} and 3×10^{-37} cm^{-1} for benzene and ethanol at optimum designing condition when the operating frequency is 1.5 THz.

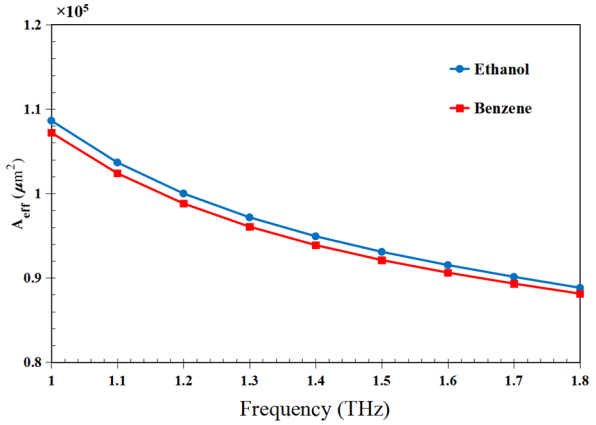

Fig. 8. Effective area of the proposed PC-PCF for different operating frequency at **D**=170 µm.

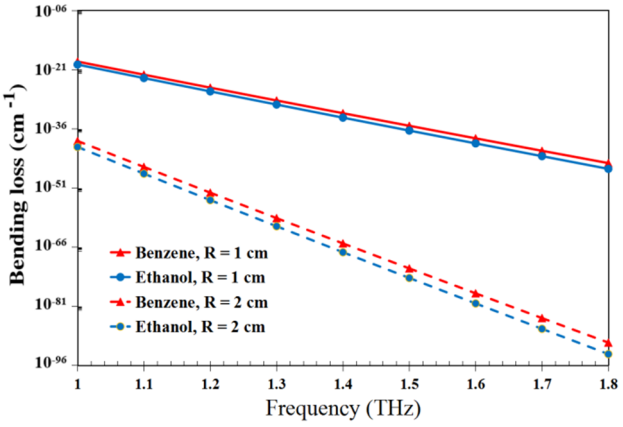

Fig. 9. Bending loss of the proposed chemical sensor as a function of frequency for D = 170 µm

When digital light signal propagates through the optical waveguide, due to the material of the waveguide and the orientation of the air holes the pulse width increases and it is called dispersion. As the effective refractive index of Zeonex is almost constant so only waveguide dispersion of the proposed sensor will be investigated. The dispersion characteristics of any microstructure fiber can be easily calculated by using the following expression [5],

$$\beta_2 = \frac{1}{c}\left(2\frac{dn}{d\omega}+\omega\frac{d^2n}{d\omega^2}\right) \quad (7)$$

where $\omega=2\pi f$ and c is the velocity of light in free space and f is the frequency of the operating light signal. The dispersion characteristic of the proposed microstructure fiber is shown in fig. 10. The graphical representation confirms that the dispersion of the proposed fiber is 0.56± 0.12 ps/THz/cm for benzene and ethanol from 1.4 to 1.8 THz.

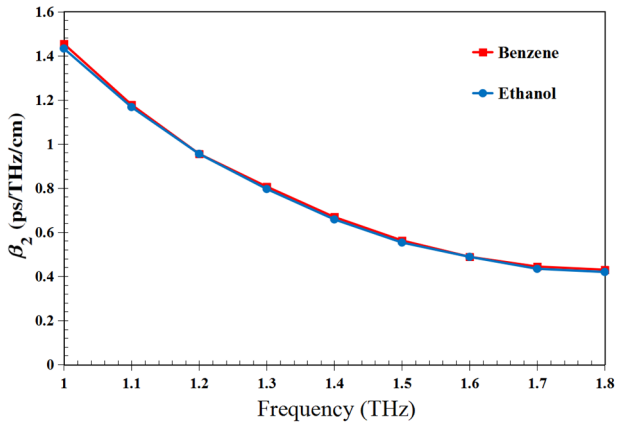

Fig. 10. Dispersion of the proposed chemical sensor for different analytes as a function of frequency at **D**= 170 µm.

At last, the possible fabrication technique of the proposed chemical sensor design. In the present age, various fabrication techniques (drilling and stacking, Extrusion, fiber drawing etc.) have invented and by using these methods various fiber can be fabricated easily and effectively. For the proposed microstructure fiber we propose Extrusion technique [16, 17] to fabricate the fiber because by using this method any kind of structure can be fabricate easily. Finally, a comparison of our proposed fiber with other remarkable chemical sensor is reported in Table. 1 and from the following table we can see that our proposed fiber is better than the reported sensor in the literature.

TABLE 1. COMPARISON OF OUR PROPOSED FIBER WITH SOME OTHER REMARKABLE DESIGNS

Ref.	Year	Operating Range	Relative Sensitivity [%]	Confinement loss [dB/m]
[12]	2016	1.33 µm	49.7	2.75×10^{-10}
[13]	2017	1.33 µm	53.35	1.6×10^{-10}
[14]	2016	1.33 µm	59.07	10^{-11}
[15]	2017	1.55 µm	65.18	5×10^{-9}
Proposed	---	**1.5 THz**	**79.2**	**3.2×10^{-9}**

IV. CONCLUSION

A new kind of porous core microstructure fiber for chemical identification is proposed and analyzed in this paper using terahertz light signal. The numerical results confirms that the proposed fiber offers very high relative sensitivity of almost 79%, very low confinement loss of 3.2×10^{-9} dB/m, very low bending loss of 4.9×10^{-36} cm^{-1} simultaneously at optimum designing parameter. The proposed fiber is very simple to realize and can be easily fabricated by using the Extrusion technique. We hope, this

sensor will be a handy one in different chemical sensing applications.

***Abstract*— The proposed fiber for THz propagation demonstrates that it has flattened dispersion with effective material loss of 0.063 cm^{-1} and confinement loss of 2.57×10^{-10} cm^{-1} . The dispersion loss of this proposed fiber is 0.5305 ± 0.05 ps/THz/cm. In this design we have demonstrated that the proposed fiber has low absorption loss due to its background material. In this design we also have discussed about other modal characteristics such as v-parameter, power fraction and also fabrication possibilities. This proposed fiber can be used for efficient and convenient transmission of THz waves.**

***Keywords*—** *PCF, Dispersion, Confinement loss, Effective material loss, THz waveguide*

1. INTRODUCTION

THz radiation, sometimes known as sub-millimeter-wave radiation, formed of electromagnetic waves between the range of 0.1-10 THz band [1]. Since THz waves operates between the infrared and microwave ranges, it carries the characteristics from both of them. Now-a-days, THz PCF is getting so much attention due to their convenient use in multidisciplinary fields like imaging [2], remote sensing [3], biomedical engineering [4]. Due to their low absorption loss and low dispersion, THz fiber is being used in biomedical engineering for different purposes like early diagnosis of skin cancer [4] , diagnosis of breast cancers [5], and diagnosis of the colon tissue cancers [6]. But THz wave communication faces various types of problems because it operates in free space medium. The whole THz system uses three parts (THz source, waveguide and detector) which are already accessible for commercial use.

Strong water vapor absorption and the misalignment issues of THz PCF are the major obstacles in THz communication. Researchers are working very hard to make THz communication very convenient with low loss. Dielectric metal - coated tube, Bragg fibers, Metallic wires were used as waveguides. But most of the fields propagates through outside of the waveguide core because these waveguides uses dielectric subwavelength and metallic wires. Now-a-days various polymers are being used as base material like PMMA, Teflon, and TOPAS for THz propagation due to their low absorption loss. Flattened dispersion is desirable in long distance THz wave communication. TOPAS is being used as base material for THz propagation due to their low absorption loss than other materials. Though a wide number PCF have been proposed in recent years, one of the researchers named Atakaramians et al. worked on dispersion properties of a porous core fiber to have low loss transmission through photonic crystal fiber [7]. Therefore porous core photonic crystal fiber is getting greater attention because of the design structure, the waveguide parameters such as core diameter, air hole radius, pitch size and air filling fraction can be determined. In this proposed fiber, we exposed a new design of PCF with circular shaped core with rectangular air hole inside the core which has flattened dispersion, low confinement loss and low effective material loss.

2. DESIGN STRUCTURE AND RESULTS

The physical structure of the proposed PCF is shown in Fig. 1. The finite element based software COMSOL 5.3a is used to make the design of the proposed waveguide. The proposed PCF is consisted of seven rectangular shape air-holes inside the core to obtain low flattened dispersion and low effective material loss (EML). In our simulation, we have used finer mesh to have the better accuracy for our design. In our proposed design, the optimum core diameter (D_{core}) is 350 μm and operating frequency is 1 THz, because the results are better. In Fig. 1, the cladding region is formed of different rectangular shaped air holes whose lengths are defined as L, L_1, L_2, L_3 respectively. The defined lengths in the proposed fibers are 683 μm, 633 μm, 501 μm and 292 μm respectively. Here d is denoted as the center to center distance of the rectangular air hole inside the core which is around 70 μm. We have used Topas as a background

material which is commercially known as cyclic olefin copolymer (COC) in our proposed PCF. It has refractive index of 1.5258 and it is constant over 0.1-2 THz wave propagation. The best advantages of our proposed PCF is its simplicity and low dispersion and confinement loss.

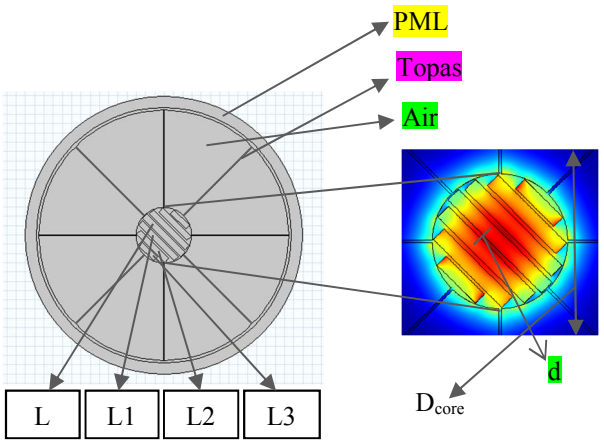

Fig. 1. Cross sectional view of the proposed PCF

THz wave propagation mostly suffers from effective material loss or material absorption loss. EML is the major loss of any proposed fiber that can be calculated by the following expression [8],

$$\alpha_{eff} = \sqrt{\frac{\varepsilon_0}{\mu_0}} \left(\frac{\int_{mat} n_{mat|E^2|\alpha_{mat} dA}}{|\int_{all} S_z dA|} \right) \quad (1)$$

Here, n_{mat}, α_{mat}, ε_0, μ_0 are the refractive index, bulk material absorption loss, permittivity and the permeability of the free space. From our proposed PCF we have found the material loss of 0.063 cm^{-1} at 1 THz frequency that is shown in fig. 2. Fig. 3. Also shows the EML variation at different D_{core} at 1.0 THz frequency. EML increases with the increase in D_{core} because of increase in material in the core region.

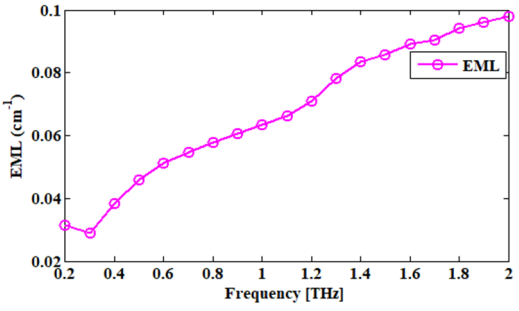

Fig. 2. EML variation at different frequency

Another parameter that is also important for any proposed PCF is confinement loss. It generally depends on the core porosity of the fiber and be calculated by the following expression [9],

$$L_c = 8.686 \left(\frac{2\pi f}{c}\right) Im(n_{eff}) \frac{dB}{m} \quad (2)$$

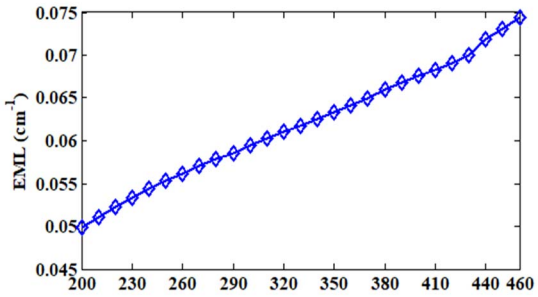

Fig. 3. EML variations at different core diameter

Here, $Im(n_{eff})$ denotes the refractive index and f denotes the operating frequency. From fig. 4. We can see that , the confinement loss is decreasing with the increase of the core diameter. At optimum parameters, we have found that the confinement loss is only 2.57 × 10^{-10} cm^{-1}.

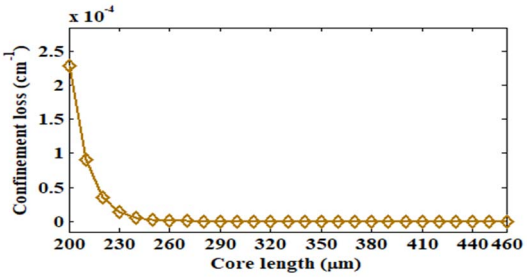

Fig. 4. Confinement loss as a function of frequency at D_{core}=350 μm

Another important parameter for a PCF is power fraction. From the power fraction we can find percent of the light intensity through different region of any fiber. From fig. 5, we can see, the light propagation intensity through different medium at [0.2-1.8] THz frequency range. Power fraction of a photonic crystal fiber can be calculated from the following equation,

$$n' = \frac{\int_x S_z dA}{\int_{all} S_z dA} \quad (3)$$

Where X represents the core, cladding or material region. In our proposed fiber, we have calculated the power fraction (light intensity) through core, cladding and material regions. At optimum operating parameters above 65% light passes through the core air-holes which is much better result compared to recently proposed models.

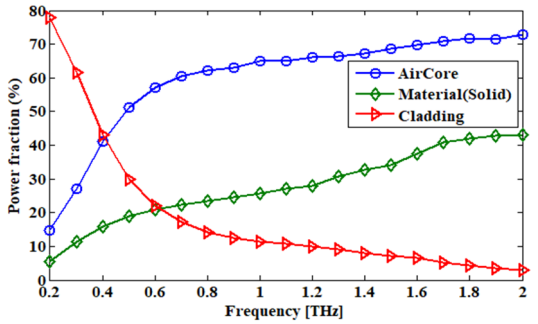

Fig. 5. Power fraction (%) at different frequencies for D_{core}=350 μm

We also have discussed about the waveguide dispersion. Due to consideration of the dispersion, we have given a great attention to the structure of our proposed PCF. The waveguide dispersion of PCF can be obtained by the following equation [9],

$$\beta_2 = \frac{2}{c}\frac{d_{n_{eff}}}{dw} + \frac{w}{c}\frac{d^2 n_{eff}}{dw^2} \qquad (4)$$

From our simulation, we have obtained a nearly zero flat dispersion of 0.5305 ± 0.05 ps/THz/cm in THz frequency range of 1.0 - 1.8 THz which is shown in fig. 6. In our proposed PCF, we have introduced rectangular air shape inside the core to have flat dispersion.

We have designed our fiber for the single mode propagation and that can be calculated by using V-parameter. V-parameter can be expressed by the following expression [10],

$$V = \frac{2\pi r f}{c}\sqrt{n_{co}^2 - n_{cl}^2} \leq 2.405, \qquad (5)$$

Here, f is the operating frequency, c is the velocity of light, n_{co} and n_{cl} indicates the refractive index of the core and cladding. We have assumed n_{cl} = 1 because of suspended core. From fig.7. we can see that single mode always exists up to 1.7 THz.

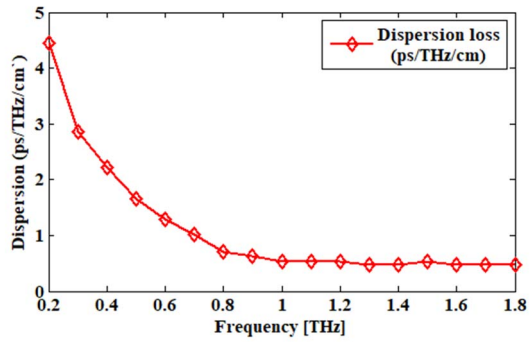

Fig. 6. Waveguide dispersion versus frequency at D_{core} = 350 µm

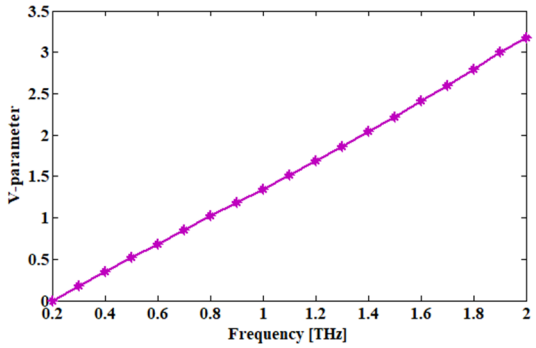

Fig. 7. V-parameter at different frequency for D_{core} = 350 µm

V-parameter as a function of core diameter is also shown in fig. 8. Our proposed PCF acts as a single mode fiber up to 440 µm.

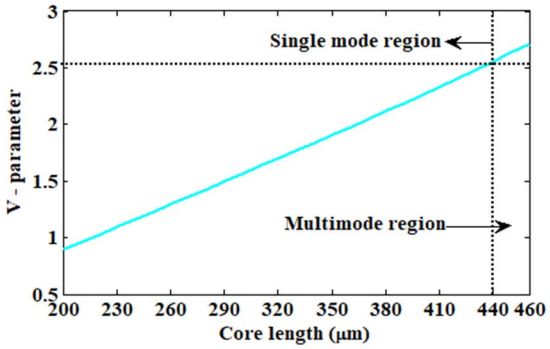

Fig. 8. V parameter of the proposed PCF as a function of core diameter at 1.0 THz frequency

Finally, fabrication is an important issue for every PCF. There are a lot of methods available to fabricate PCFs commercially. Sol-gel, drilling and drawing, stack and draw, extrusion, 3D technology are such methods. As our proposed fiber contains non-circular air-holes, extrusion technique can be used to fabricate our design. In addition, micro-structured polymer optical fiber with asymmetric air holes is also feasible using 3D printing technology

3. CONCLUSION

In summary, a completely new circular shaped air core with rectangular shaped air-hole PCF is proposed in this paper. Since Topas has low bulk material absorption loss and zero material dispersion, it is used as the background material in our design. A thorough numerical investigation has been used which shows an EML of 0.063 cm^{-1} , low confinement loss of 2.57 × 10^{-10} cm^{-1} for 350µm core diameter at 1.0 THz operating frequency. A nearly zero flat dispersion of 0.5305 ± 0.05 ps/THz/cm in frequency range of 1.0 - 1.8 THz is also obtained. The fabrication of this proposed PCF is feasible because of its realistic size and simplicity. Since this proposed fiber has low loss with flattened dispersion, so this PCF can be a potential candidate for applications in long distance THz wave propagation.

Abstract—**This research paper proposes an energy generation system to utilize renewable energy for off-grid area of Bangladesh which includes hill track areas and Rohinga camps. Most of the hill track areas and Rohinga camps did not access electricity. Again, present system loss of electricity is a great problem in Bangladesh. The main purpose of the paper is to design an optimal hybrid energy management system using HOMER control technique and Fuzzy Logic Controller (FLC). The system consists of PV arrays, Biogas generator, diesel generator, converter and Battery. We have used the HOMER software for effective size calculation of the system components. FLC is used to manage the obtained power from renewable energy sources efficiently. Optimum fuzzy rules are designed to control the shifting of the switches considering the load profiles and availability of renewable sources on a given period of time. For the justification of cost effectiveness and power management system simulation result from our control strategy have been compared with other prevailing systems. In addition, we obtain lower CO_2 emission from the system renewable fraction which indicates the environment friendliness. This simulation result provides a summary to utilize renewable energy with properly on recent energy crises in Bangladesh.**

Keywords—**Hybrid energy generation system; PV array; Biogas; Hybrid optimization of multiple energy resources (HOMER); Fuzzy logic controller (FLC);**

I. INTRODUCTION

The capacity of installed electricity generation in Bangladesh is about 15,755 MW in 2017 which does not exist for total population [1]. About 71.42% electrical energy comes from natural gas followed by furnace oil 15.44%, diesel 2.91%, and imported 5.37% those are limited [1]. Since, energy cannot be created or destroyed, so the source of non-renewable energy will run out very rapidly. It also increases air, water and soil pollution, greenhouse gases with the amount of carbon dioxide emission that attributes to global warming. Again energy consumption is increasing day by day. On the other hand, most of the hill track and remote areas are out of electricity. So, energy generation from renewable sources is the best choice for protecting the environment and fulfilling the total load demand of those areas. It is a solution towards the limited availability of fossil fuel and climate change.

There are many kinds of renewable sources such as solar energy, hydro energy, wind energy, tidal energy, geothermal energy and biomass energy etc. Among them Solar and biogas energy are more suitable for electricity generation in hill track areas, remote areas and Rohinga camps in Bangladesh. Present share of renewable energy in Bangladesh is only 1% which envisions having 10% by 2020 which is shown in Table I [2]. The target of our government about electricity generation from renewable sources for domestic house is 2,470MW within 2021, and 3,864MW within 2041. Again, according to the view of government, the production of biogas from domestic house is 600,000 m^3/day by 2031 which will be increased to 3 million m^3/day by 2041 [2]. In Bangladesh, cattle dung is available from 11.6 million cows, buffaloes, goats and sheep [3]. One kilogram of dung can produce .037m^3 biogas. Therefore, available dung of cattle and buffaloes can produce $2.97x10^8$ m^3 of biogas which is equal to $1.52x10^6$ tons of kerosene or $3.04x10^6$ tons of coal [3]. So, generation of electricity from biogas is an enormous source in Bangladesh. Besides, a substantial amount of biogas can be produced from human and animal excreta, garbage water hyacinth and forest residue. Therefore, the combination of solar energy and biogas energy can play a vital role to fulfill the load demand for those areas. This paper is offered for multi households with 220 kW load demand in a day. The available average solar radiation is 4-7kWh per square meter per day on that area with near 250–300 sunshiny days in a year that can eliminate a precent of the total load demand in this area [4]. Again the fuel of biogas energy is also available in this area which can mitigate a large amount of load demand of required energy.

TABLE.I RENEWABL EENERGY STATUS IN BANGLADESH [2].

Category	Achievement (MW)	Target (MW)
Solar Energy	More than 300	1800
Wind Energy	2	364
Biomass Energy	Less than 1	45
Biogas Energy	Less than 5	9
Hydro Energy	230	237
Other RE	Less than 1	15
Total	539	2,479

To minimize the system loss and increase efficiency, effective energy management system is most important. So, an Artificial Intelligence (AI) as fuzzy logic controller in MATLAB is one of the most widely used applications of fuzzy set theory that is used for management system which must minimize power loss [5]. This management system is one of the more effective systems that optimize energy efficiency. The control strategy based on fuzzy logic theory has been proposed to achieve the optimal result of the battery charging/discharging, PV operating condition, biogas generator and diesel generator off-on performance.

II. METHODLOGY

A. STUDY AREA & RESOURCES ASSESSMENT

In this research, study area has been selected for Bashkhil in Boalkhali Chittagong that is located at 22 degrees 50 minutes North latitude and 92 degrees 22 minutes East

longitude [6]. It is a hill track area in where solar and biogas fuel is available and most of the people are not access of electricity. About 140-150 family can get benefit of electricity from this study by utilizing renewable energy for 220 kWh load demands for a day. Overall research method has been presented in Fig. 1.

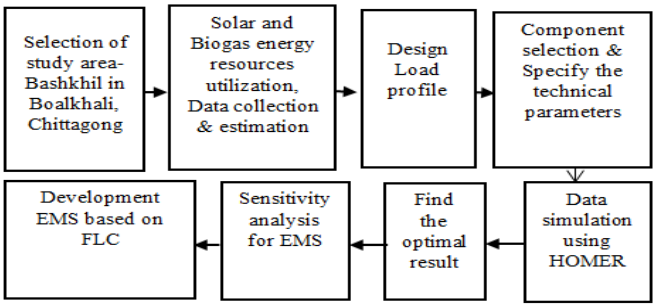

Fig.1 The overall methodological outline of the research.

For this research typical monthly solar radiation data has been collected from NASA by using Homer that is shown in Table II.

TABLE II. AVERAGE SOLAR RADIATION AND BIOMASS FUEL IN PROPOSED AREA [6].

Month	Clearness Index	Daily Solar Radiation (kWh/m²/day)	Daily Biomass (ton/day)
January	0.641	4.523	1.5
February	0.616	5.005	1.2
March	0.605	5.699	1.3
April	0.552	5.781	1.2
May	0.528	5.807	1.2
June	0.390	4.344	1.2
July	0.362	3.987	1.1
August	0.403	4.272	1.3
September	0.417	4.064	1.2
October	0.575	4.874	1.3
November	0.597	4.345	1.3
December	0.649	4.350	1.4
Average	0.641	4.523	1.26

By investigation the study area, total number of the cows is 50. Dung potential for total cows is 500 kg/day. Domestic waste potential is 250 kg/day and forest residue is 400 kg/day. Total compost manufacture is 1500 kg/day. From this manure, the potentiality of biogas is 75 m^3 /day which are shown in Table III. Biogas produces by Photosynthesis process. Photosynthesis can be described by flowing chemical reaction [7]:

$C_6H_{12}O_6 + 6\ O_2 \text{ ---> } 6\ CO_2 + 6\ H_2O + 19\ MJ\ /m^3$ ……(1)

Where, $C_6H_{12}O_6$ represents biomass resource.

TABLE III. BIOGAS RESOURCESS UTILIZATION OF PROPOSED AREA [6]

Specifications	Details
Total Domestic Waste	250kg/day
Total cow	50
Forestry residue	400kg
Dung for one cow	10 kg/day
Overall dung	500 kg/day
Other manure	350 kg/day
Gas profit	.05 m^3/kg
Total amount of biogas	75 m^3
1 m^3	19 MJ
Total electricity produced	1425 MJ = 395 kWh
Efficiency of Generator	35%
Overall electricity produced	138 kWh/day

B. SYSTEM DESCRIPTION

The proposed hybrid system consists of PV arrays, Biogas generator, Diesel generator, converter and batteries which is shown in Fig. 2. According to load demand, PV array and Biogas generator, Diesel generator supply electricity. The extra energy from PV and Biogas generator is stored in the battery until full charge. When generation of electricity from PV and Biogas generator, Diesel generator is unavailable, then battery is used as backup system. The converter is recovered as an inverter and rectifier.

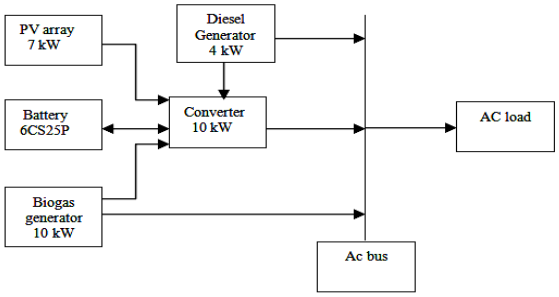

Fig.2 Block diagram of the system.

C. PV array

Photovoltaic (PV) array produce electrical energy through semiconductor materials from light energy based on a phenomenon called photovoltaic effect [8]. Generated power from PV array can be denote by below equation [9]

$$P_{pv}(t) = \eta_{pv} . A_{pv} . S(t) \text{..... ....} (2)$$

Where, η_{PV} – efficiency PV arrays, A_{PV} - total area of PV array in m^2 and S(t) - solar radiation kW/m^2. Average monthly solar radiation from January to December has been presented in Fig. 03.

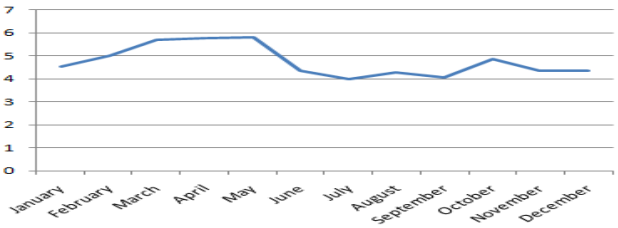

Fig. 3 Average monthly solar radiation.

For proposed system, 350 watt of 72pic Mono crystalline Silicon SKT350P-12 PV array has been considered. By optimizing, we have got 7 kW PV arrays according to HOMER software. The capital cost, replacement costs and lifetime of PV arrays have been considered $700, $600 and 25 years respectively which is shown in Table VII.

D. Biogas model

Biogas generally is the combination of different gases like (CH_4, CO_2, H_2S) that composed from farming waste, manure, municipal waste, forest deposits, plant material, sewage, green waste or food waste by the breakdown of organic matter in the absence of oxygen [10]. Biogas is a kind of renewable energy source because of it's created from atmospheric carbon by plants grown within current growing seasons. Generated gas is used as fuel that can be used as heating purpose or cooking purpose. This gas can also be used to generate electricity through gas engine. General specification of biogas generator which is shown in Table V. Fig.4 indicates monthly average biomass fuel in ton.

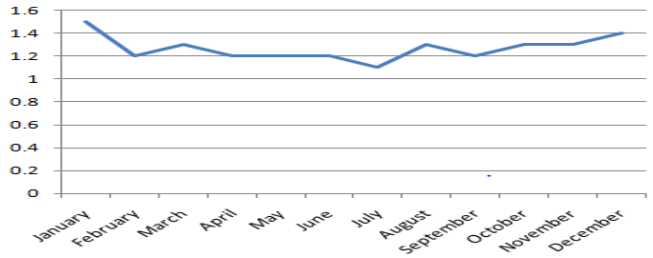

Fig. 4 Monthly average biomass fuel in ton.

TABLE V. GENERAL SPECIFICATIONS OF BIOGAS GENERATOR [11]

Specifications	Details
Model	YDNY-10
Output	AC 3 phase, 50 Hz
Rated Power	10kW/12.5Kva
Rated Current	18 A
Fuel	Biogas
Gross Weight	510 kg
Rated Speed	1500 rpm
Gas Consumption	6.5 m^3/h
No. of Cylinder	4

The capital cost, replacement cost and operation time of biogas generator is considered $1100, $1000 and 20,000 hours which is shown in Table VII.

E. Generator model

A diesel generator is a machine that connects with a diesel engine with an electric generator to produce electricity by rotating the alternator [12]. The working principle of diesel engine depends on Carnot cycle. Again, the mechanism of electric generator depends on principle of electromagnetic induction. General specification of diesel generator which is shown in Table VI.

TABLE VI. GENERAL SPECIFICATIONS OF DIESEL GENERATOR [13]

Specifications	Details
Model	POWERHOUSE, PH3826
Output power	AC, 3 phase, 50 Hz
Rated Power	4.8kW
Fuel	Diesel
Fuel volume	16 L
Rated Speed	3400 rpm
Oil Consumption	1.9 L/h

The capital and replacement cost of diesel generator is considered $150 and $130 for 1 kW which is shown in Table VII. The lifetime of diesel generator is considered 30,000 hours.

F. Battery model

Battery is used to stock extra energy from renewable sources that will be used when the system is not capable to give required power. The lifetime of battery depends on charge or discharge rate per day. By optimizing input data, we have got the number of battery having capacity 11 of 6CS25P model 6 volt 820Ah 6.94kWh. The capital and replacement cost of the battery is considered $1100 and the replacement cost $1000 for five years [14].

G. Converter model

Converter is used as both rectifier (AC to DC) and inverter (DC to AC). By simulation, the program finds an optimum result 11kW for converter. The capital cost and replacement cost of converter is considered $180 and $150 per kW for 15 years which shown in Table VII [14].

H. Load profiles

TABLE VII. THE INPUT HYBRID SYSTEM COMPONENTS.

Quantity	Size (kW)	Capital ($) for 1 kW	Replacement ($) for 1 kW	O & M ($) per year	Life Time
PV arrays	7	700	600	10	25 year
Biogas generator	10	1100	1000	1539	20000 hour
Diesels Generator	4	150	130	233	30000 hour
Battery	6.94kWh	1100	1000	8	5 year
Converter	10	180	150	5	15 year

The target of load demand is 220 units per day for selected zone. Daily load profile is presented in Fig. 05 (summer season) and Fig. 06 (winter season). Day to day load variation has been considered 16% and time to time load variation has been considered 22%.

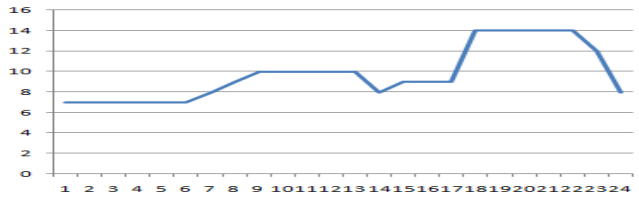

Fig. 5 proposed daily load profile for March to November in kW.

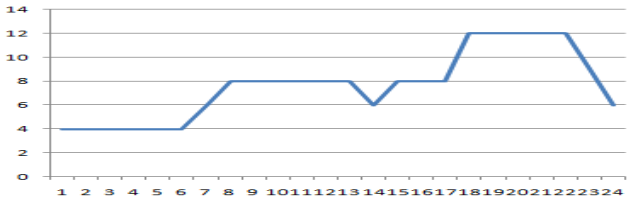

Fig. 6 proposed daily load profile for December to February in kW.

This proposed system is designed for four or five family member with 150 to 170 families. We consider typical electrical appliances such as CFL bulbs, electric Fan, TV, electronics charges in each family with standard voltage (220V AC, 50Hz). Table VIII presents the electric load characteristics of each house.

TABLE VIII. ELECTRIC APPLIANCES OF HOUSE.

Domestic Appliances	Number of Appliances	Power in watt	Summer (Avg. hr./day)	Winter (Avg. hr./day)	Approximate Total (kWh/day)	
					Summer	Winter
CFL Bulbs	3	20	9/10	10/11	1.508 kWh/day	.738 kWh/day
Ceiling Fan	2	35	10/11	0		
TV	1	18	4/5	4/5		
Mobile Charger	2	6	3/4	3/4		

III. OPTIMIZATION MODEL USING HOMER

Total Architectural view of research has advanced with the load profile, solar & biomass resources, system component as input of HOMER. Net present cost, optimum result, cash flow, and total capital cost, energy saving cost, renewable energy fraction, and excess energy fraction% as output by Homer. The configurations of proposed system's component are PV array, biogas generator, diesel generator, battery and power converter. PV array and Biogas generator are main renewable sources of electricity. Generated current from PV

array is DC. Again we used AC biogas generator. So, inverter is used to change DC to AC and vice versa to adjust overall system. The simulation diagram of proposed system is shown in Fig. 7.

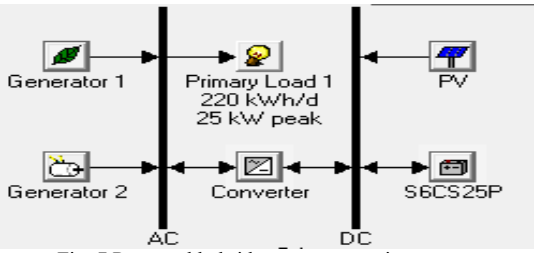

Fig. 7 Proposed hybrid energy generation system.

IV. POWER MANAGEMENT MODEL USING FLC

A fuzzy inference system (FIS) is a kind of artificial intelligence system that is created on a fuzzy set and IF-THEN rules [4]. Fuzzy logic can make ideas that not only "true" or "false" but also incomplete truth in where the truth rate may range between absolutely true and absolutely false [15]. It has four main parts i) Fuzzification which changes a actual value into a fuzzy set, ii)Knowledge base depends on IF-THEN rules, iii)Inference Engine depends on human analysis that create fuzzy inference between inputs and IF-THEN rules, iv) Defuzzification converts to real value as output from the fuzzy set which obtained from inference engine [15]. Fuzzy logic method is capable to apply in knowledgeable control system, nuclear fusion in order to increase efficiency and simplicity of the design procedure. Proposed management system has been developed based on FL technique using a Mamdani interface system.

The system consists of five inputs and four outputs shown in Fig. 8. The five inputs are PV (have four triangular membership function zero, low, medium, high shown in Figure 9), biogas generator, diesel generator, Load demand (LD) and State of Charge (SOC). Biogas generator and diesel generator have two triangular membership functions representing available and not available shown in Fig. 10 & 11. Last two input of load demand (LD) and state of charge (SOC) have three triangular membership functions of low, medium and high representing for 24 hours shown in Fig. 12 & 13. Four output membership function are PV-OFF-ON, BIOGAS-OFF-ON, GENERATOR–OFF-ON and Battery_NU_C_DC(B). PV-OFF-ON, BIOGAS-OFF-ON and GENERATOR–OFF-ON have two switches as OFF (S1) and ON (S2). Battery_NU_C_DC(B) has three switch as not use (S1) charge (S2) and discharge (S3

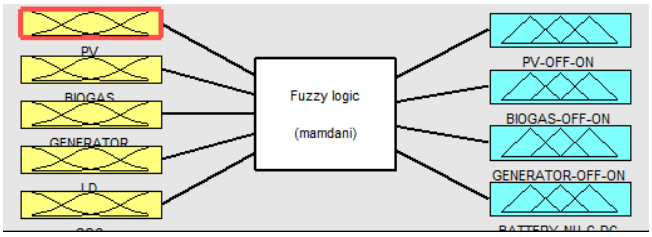

Fig. 8 Block diagram of proposed fuzzy logic controller

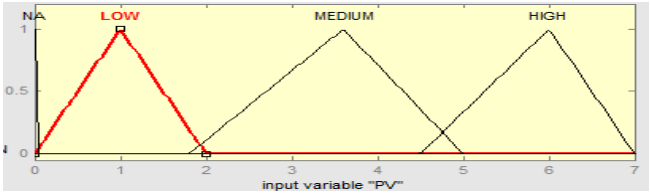

Fig. 9 Membership function of PV array

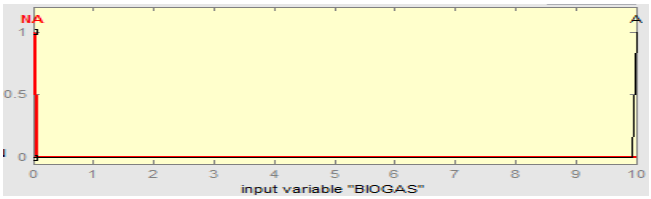

Fig.10 Membership function of Biogas Generator

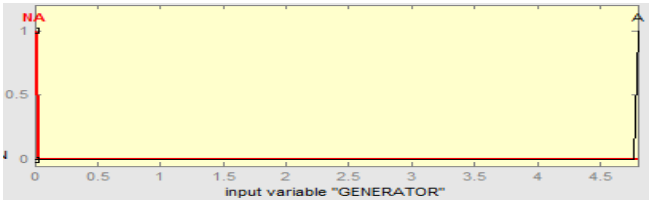

Fig.11 Membership function of Diesel Generator

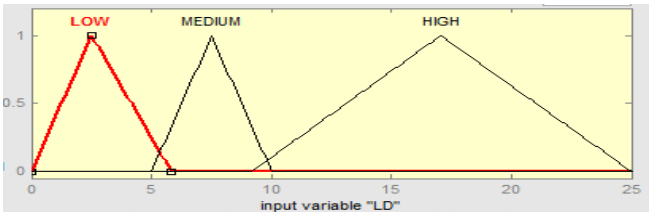

Fig.12 Membership function of Load demand

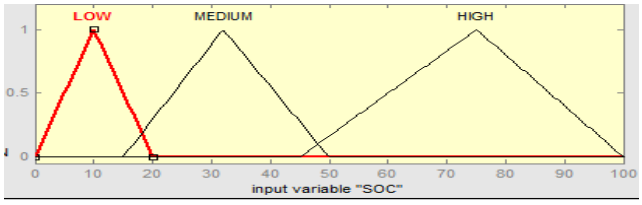

Fig.13 Membership function of SOC

FLC is related to inputs and outputs segment with a list of IF-THEN statements which is known as fuzzy rules. The IF known as input parts and THEN known as outputs part. In this research, we have established 24 rules to develop effective energy management system for different operational conditions which is shown in Table IX.

TABLE IX. CONSIDERING FUZZY RULES

		IF					THEN

V. RESULT & ANALYSIS

On the basis of HOMER software requirement as input data of solar & biomass rescores, oil consumption and load demand, we have got some optimum & one sensitive result by simulation which is shown in Fig. 14.

	PV (kW)	Label (kW)	Label (kW)	S6CS25P	Conv. (kW)	Initial Capital	Operating Cost ($/yr)	Total NPC	COE ($/kWh)	Ren. Frac.	Diesel (L)	Biomass (t)	Label (hrs)	Label (hrs)	Batt. Lf. (yr)
	7	10	4	11	10	$ 30,300	11,500	$ 177,303	0.173	0.90	2,700	198	7,528	2,850	12.0

The annual electric energy production and consumption parameters from system which is shown in Table X. Average monthly generated electricity in the system which is shown in Fig. 15.

TABLE X. ELECTRIC ENERGY PRODUCTION & CONSUMPTION PARAMETERS.

Production	KWh/yr	Fraction in%	Consumption	KWh/yr
PV array	10547	12	AC load	80268
Generator 1	65199	77	Excess electricity	123
Generator 2	8692	10		
Total	84438	100	Total	80268

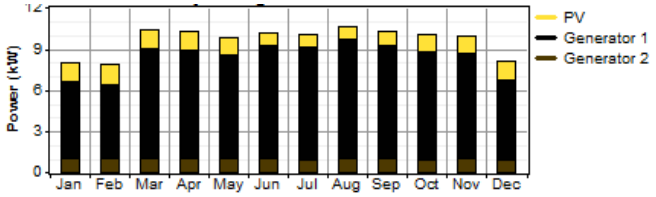

Fig.15 Monthly average electricity production in the system.

Fig. 16 indicates operation of PV array. Yearly electrical production is 10,547 kWh/yr. Maximum electrical output is 6.94 kW. Mean electrical output is 28.9 kWh/day. Capacity factor is 17.2%. Total operation hours is 4,375 hr/yr .

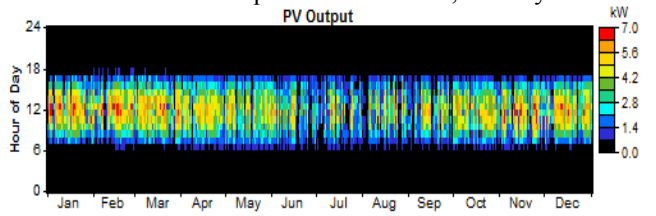

Fig.16 PV operation in the system.

Fig. 17 indicates operation of biogas generator. Yearly electrical production is 65,199 kWh/yr. Maximum and minimum output is 10 kW and 3 kW. Mean electrical output is 8.66 kW. Fuel consumption is 198 ton/yr. Specific fuel consumption is 2.124 kg/kWh and efficiency has been considered is 35% . Capacity factor is 74.4%. Total operation hours is 7,528 hr/yr .

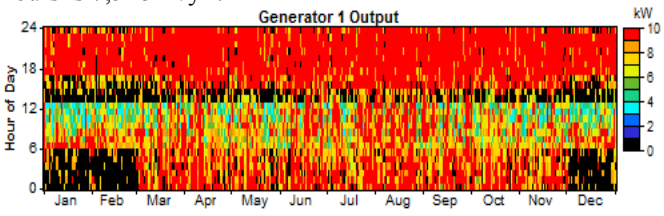

Fig.17 Biogas generator operation in the system

Fig. 18 indicates operation of diesel generator. Yearly electrical production is 8,692 kWh/yr. Maximum and minimum output is 4 kW and 1.20 kW. Mean electrical output is 3.05 kW. Fuel consumption is 2,700 L/yr. Specific fuel consumption is 0.311 L/kWh and efficiency has been considered is 32.7%. Capacity factor is 24.8% . Total operation hours is 2,850 hr/yr .

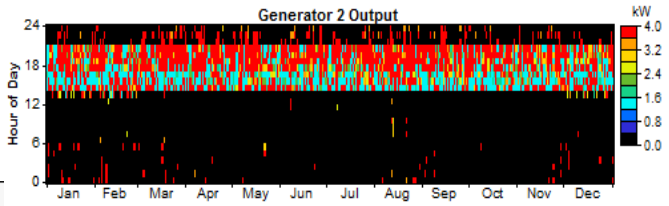

Fig.18 Diesel generator operation in the system

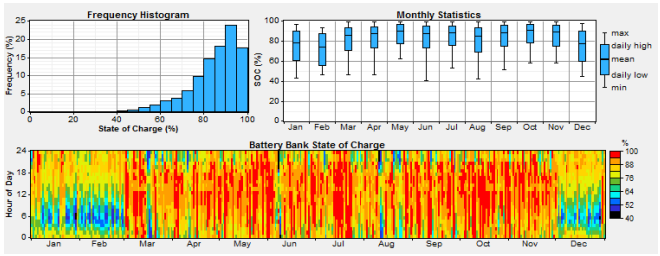
Fig. 19 indicates operation of battery. Energy in and out through battery is 8,795 kWh/yr and 7,044 kWh/yr . Total loss is 1,743 kWh/yr in rectifier.



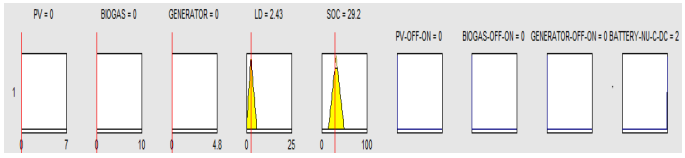


Fig.19 Battery status in the system.

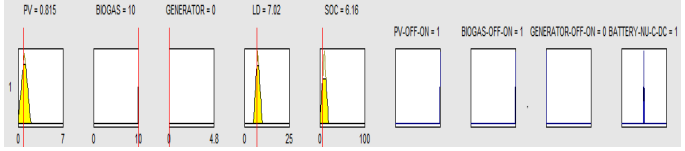
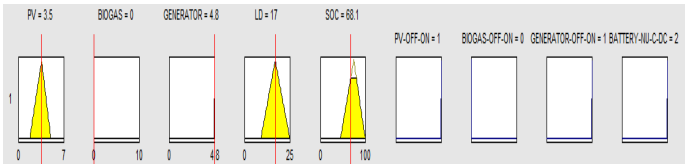


VI. MANAGEMENT STRATEGY EVALUATIONS

By optimizing input data of load demand, solar-biomass resources and system component, we have got 7 kW PV array, 10 kW biogas generator and 5 kW diesel generator. So the range of input membership function of PV array, biogas generator and diesel generator are 7kW, 10kW and 5kW. Fuzzy logic controller is designed with 24 rules for winter and summer season. We have generated only effective rules based on human knowledge that must minimize power loss. Optimum power is obtained through the tuning of fuzzy rules that depends on our thinking and analysis. At a time we have used different rules for meeting any condition within 24 hours, then shifted to another rules by depending on generated power and load demand.

CASE STUDY-1, FOR FUZZY RULE 1(TIME,00-6)
At night, when PV is not available, Biogas is not available, the fuel of diesel generator is not available, load demand low and state of charge is medium then PV-Biogas generator-diesel generator are OFF,Load demand is fullfiled by battery.



CASE STUDY-2, FOR FUZZY RULE 3(TIME,6-10)
At morning, when PV is low, Biogas is available, the fuel of Diesel generator is not available, load demand medium and state of charge is low then PV is ON, Biogas generator is ON, Diesel generator is OFF, Load demand is fullfiled by PV and Biogas. At a time extra power is used for bettery charge.

CASE STUDY-3, FOR FUZZY RULE 22(TIME,15-16)
At afternoon, when PV is Medium, Biogas is not available, the fuel of diesel generator is available, load demand is high and state of charge is high then PV is ON, Biogas generator is

OFF, Diesel generator is ON, Load demand is fullfiled by PV and diesel generator. But diesel generator and PV are not capable to fulfill the total load demand . So, bettery is discharge.

VII. COST SUMMARIES

Cash flow summary and net Present cost summary in terms of component are shown in Fig. 20 & 21 respectively. The system cost is defined as equation.

$$C_{SYSTEM} = C_{PV} + C_B + C_G + C_{BA} + C_{CON} \quad \text{.....(3)}$$

Where, Cpv indicate PV array cost, C_B indicate biogas generator cost, C_G indicate diesel generator cost, C_{BA} indicate battery cost and C_{CON} indicate converter cost [15]. Total net present cost is \$177,303, levelized cost of energy is \$ 0.173/kWh and operating cost is \$ 11,500/yr.

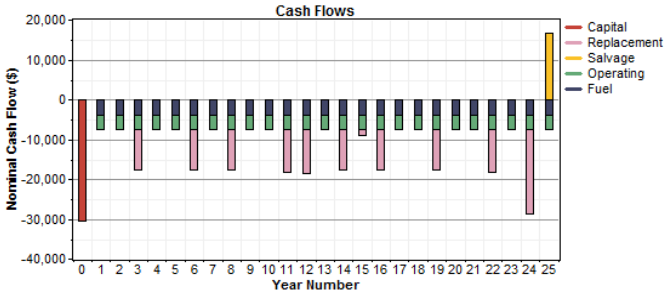


Fig. 20 Cash flow summary based on the selected components.

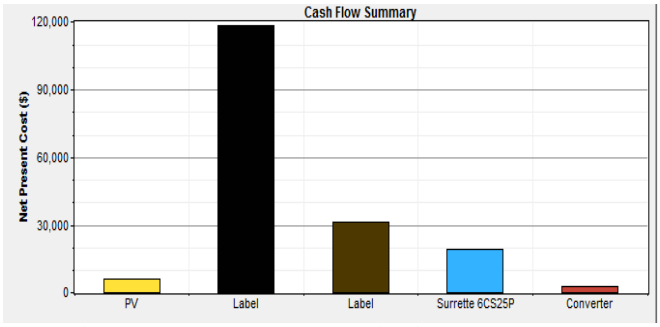

Fig. 21 Net present cost summary of each component.

VIII. CONCLUSIONS

The application of renewable energy is growing rapidly in all fields of the engineering to minimize CO_2 gas emissions in the system. This hybrid model is more effective than any other conventional systems that can easily applicable in everywhere in Bangladesh specially hill track areas, remote areas and Rohinga camps in where electricity is not available. By applying this proposed system, we can easily manage our domestic wastage and forest residue. HOMER Software is used to carry out optimal power based on load profiles and available renewable resources. Fuzzy Logic Controller (FLC) is used to manage the energy of the system properly. Component sizes calculation of PV arrays, biogas generator, diesel generator, battery and converter have been selected by using HOMER software and those are used as input of FLC for effective management system to reduce energy loss. Cost summary, cash flow summary and electrical production are the result of optimizing input data from HOMER. The solar energy, biogas energy and diesel generator contribute 12%, 77% and 10% respectively to generate power. Besides, the system is atmosphere approachable and favourable. The proposed system decreases CO_2 emissions and delivers clean energy that reduces our power crisis.

***Abstract*- Mobile devices or portable smart gadgets are largely used in our day-to-day life now. These devices can be very useful in helping people who are visually impaired and assist them to make their life easier. This paper presents an android application that recognizes objects using real time object and text detection by scanning them. The application can run on the device without any remote server. Our solution uses a voice feedback to tell the user about the detected object. The app doesn't need any photograph to detect the object. To enable robust recognition, we first segment the object from the background using tensorflow machine learning API based on iterative diagram cuts. We then formulate the recognition problem as an instance retrieval task and the user gets to know the object through a text to speech method. The system is designed to help a visually impaired person know about the environment around them. This app can be run on any low-end smartphone devices.**

Keywords- visually impaired; android application; scanning; TensorFlow; text to speech; image recognition; text recognition.

.

I. INTRODUCTION

Mobile phone has become a very significant device for out day to day life. Information of the whole world is in our hands due to this device. Nowadays we cannot imagine living without a mobile phone for even a day. From food to deliver service to calling taxi services, we are all dependent on mobile phones and it's applications. The use of mobile phone is growing every day. This is because it makes our life easier and makes various services easily accessible. According to GSMA data, which is an online mobile reviewer plateform, it is expected that the number of mobile phone user will pass around 5 billion [1]. In 2016, 56 percent of population in worldwide has owned mobile phone already and especially the use of smartphone is rapidly growing [2]. By 2014, it is estimated that around 70 percent of population were smartphone user [3]. By 2019, it is expected that the number of smartphone user will grow by 2.7 billion. The statistic can be seen in Figure 1.

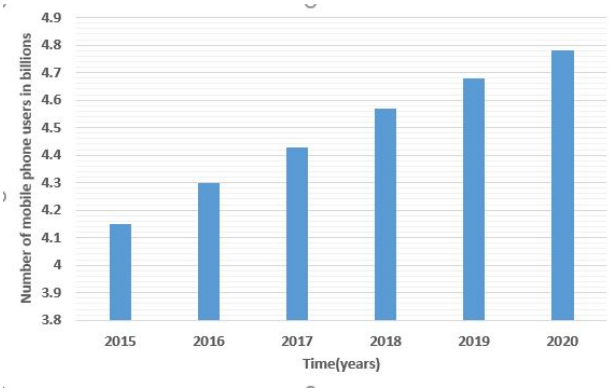

Figure 1. Number of mobile phone users between 2015 to 2020 (in billions)[4].

Visual impairment does not always mean complete loss of eyesight. According to the World Health Organization there were more than 285 million visually impaired living in the world in 2012 [5]. Even a slight visionary inability can affect a person's day to day life hugely. As represented in Figure 2 the number of visually impaired people have increased all over the world.

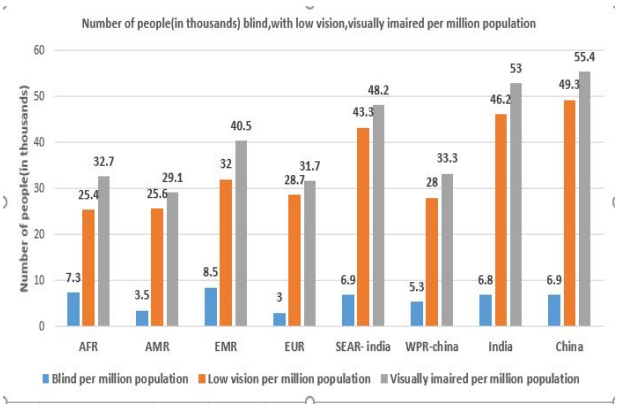

Figure 2. Number of people (in thousands) blind, with low vision & visually impaired per million population [6].

The inability to see the surrounding makes it difficult to move around or do anything on one's own. A lot of objects have the same texture or shape which makes it even harder for a visually impaired person to sense what objects are around or they holding. Nearly one-third of people with vision loss suffer from clinical depression, a rate that is twice as high as the general population of the

same age [7]. Visually impaired people suffer in many ways. The proposed system is an android application that detects objects by scanning them and replying with a voice feedback that can assist any visually impaired person. As usage of mobiles have increased and price has reduced in the past few years drastically, this vastly used and easily accessible device seemed better choice for this system.

II. SMARTPHONE APPLICATIONS

There are quite a few applications out there in the market that is similar to ours. Some of them are costly to use. This application is open to all. Existing applications are mostly used to detect currency bills of different countries. A few of them are there that detects objects around them. But nearly all of them requires taking a picture of the object or the bill and save it in memory before it can detect what object it is. What makes our application different from all the others is that our application does not need to take a picture of the particular object, but instead it scans the object and recognizes the object using real time object detection. It is easy to use for blind people. That way the visually impaired does not have to worry about taking a proper picture nor does he have to worry about.

A. How does it work

We have used two features for the application. A user can recognize object and can hear any text over voice. So, for these two features we have used an open source machine-learning framework, which helps to detect any object and google text to speech API to recognize text.

I. Object Detection

In this case, when a user wants to detect what object is it or what is the name of a particular object the user needs to open camera. For this, we used google camera API that can detect camera hardware information and eventually open the camera. For displaying any object texture View class is used to take frame. Later by using TensorFlow machine learning framework we have trained our dataset and then imported the trained dataset. For detecting object our algorithm take input by using camera and feed the input to the algorithm then communicate with trained model and eventually make the prediction. Figure 3 represents how algorithm actually works to detect object.

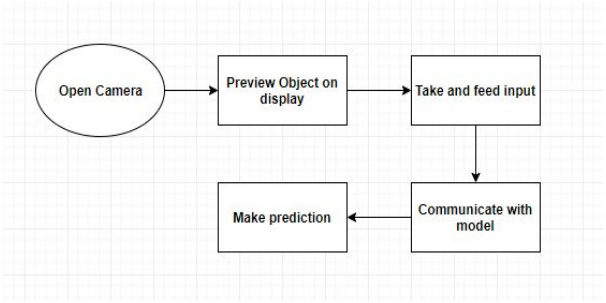

Figure 3. Flow chart showing object detection algorithm works.

II. Recognize Text

Optical Character Recognition (OCR) gives a machine power to read any text. OCR is the best way to recognize any text which make visually impaired user able to hear text out loud. Camera takes individual frame using detect methods and TextRecognizer. To read any text straight from camera, when any texts become available we have implemented processor in OcrDetectorProcessor which handle all the detections. From TextRecognizer ReceiveDetections will receive text blocks when text becomes available. For this, Text Recognizer is used to detect image and process the image that determines what text appears within the image and finally make an audio synthetic voice using text to speech API to give output. Figure 4 illustrates how the text to speech API works in that application.

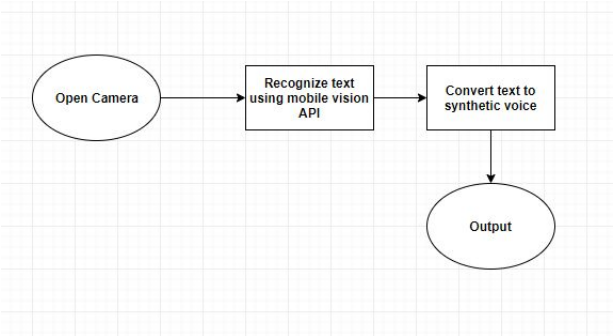

Figure 4. Flow chart of text to speech algorithm.

B. How to use

Visually impaired have difficulty being aware of their surrounding and recognize objects. In our app, at first they need to open the app and it will start working without any other command. The mobile camera will scan the object and the real time data will be processed evaluated with the system dataset and finally it will give the result. A user can just open the app using Google assistant just using voice. Later the user is asked whether the user wants to recognize object or recognize text. Figure 5 illustrate how to use the application.

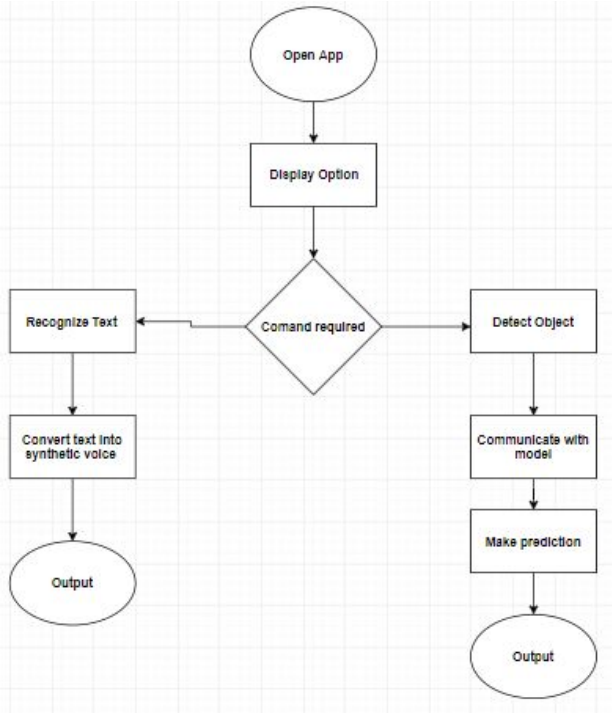

Figure 5. Flow chart showing the work of application.

III. TESTING THE APPLICATION

The whole system testing is done using a Huawei phone. In this system a user can open the application by using Google assistant and user can choose if user wants to recognize object or read any text. The system is very easy to use and user friendly. Figure 6 shows the interface. If the user chooses the "Detect Text" option then the camera opens and if you hold it against any text the app can read it out to the user. If the user chooses the "Detect Object" option then again the camera opens and if it is held against any object then the app tells the user what object it is.

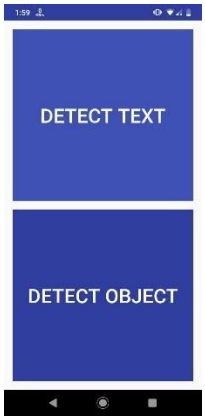

Figure 6. A user can detect object and detect text

For detection we have trained some data that are available around us. We have used tensorflow machine learning API, which is developed by Google brain team. So a user who has a poor vision can recognize any object. After testing the application we saw that the recognition accuracy for every object is more than 80 percent. So we can fairly say that if we train more data and develop the application then it will be able to detect as much objects as possible and with better accuracy rate. Figure 7 shows how a user recognize object.

Figure 7. Object recognition test.

We tested our app for recognizing text and we saw that our app can recognize all the text that we tested. As we have trained our app in English so our app can detect all texts written in English. So if the user holds the camera against a text the app gives out a clear output of the text and reads it out to the user. As our target users are visually impaired or blind people, this text recognition can help them in many ways to identify anything written around them or on any object. Figure 8 shows how text to speech works in real time.

Figure 8. Real time text recognition

IV. FUTURE WORKS

The app we have built so far is suitable to be used by people with poor vision or visually impaired. In future, we intend to add voice command so that fully blind people will be able to use the app easily. Currently the data in our app is limited data. We have used CIFAR 10 data set where there are 600 images of 10 objects, which we have trained. Our plan for the future is to work with many more data sets and to train them so that a blind or visually impaired user can use the app to recognize objects of their day-to-day life easily.

IV. CONCLUSION

Our client targeted is people who are visually impaired and we have noticed that their life is quite difficult. We created the app with features, which can help them make their life easier by knowing what's around them by using our app. We have seen that all the applications similar to ours have been made before but those app need to capture image and then return what object it is. But our application does not need to take an image and it only scan object and then tells the user what object it is. That way the visually impaired user doesn't have to delete images from memory every now and then.

***Abstract*—The general algorithms which are followed to solve the Longest Common Subsequence (LCS) problems have both time complexity and space complexity of $O(m * n)$. To reduce this complexity, two ways are proposed in this work. One is the use of Divide and Conquer approach, and another one is changing the data structure from two-dimensional array to queue. By using these approaches, an algorithm has been developed and implemented for the long length string in this paper. The time complexity after using these approaches becomes a function of logarithm $O(n * \log(n))$ which has been shown with proper explanation and the space complexity after using queue data structure becomes linear $O(n)$.**

Keywords—Longest Common Subsequence, Queue, Divide and conquer, Dynamic Programming, Recursion

I. INTRODUCTION

Longest Common Subsequence (LCS) is a popular algorithm to find the longest subsequence which is a common group of sequences. Normally, two sequences are given and from that, LCS has been found out. A subsequence is gained from another sequence by removing some elements but can't change the series of the other elements. There are many other algorithms to find common subsequence. Most of them follow the greedy approach. But LCS follows the dynamic approach. It can be decided in polynomial time.

The general LCS algorithm takes O(m*n) time. In this paper, there has been proposed an algorithm which finds the solution by following an optimal infrastructure. The problem which is given is broken into subproblems which is smaller and simple, which will be broken into yet further smaller subproblems until we find the final answer. For this approach, time and space complexity is optimal. The time complexity becomes $O(n * logn)$ for the best case and $O(n * \log(n)^2)$ for the average case. But the space complexity becomes linear by using data structure queue instead of two-dimensional array and it is $O(n)$in both best and worst cases. Although this algorithm is not unique, it can become really complex for a very bigger length. But for most of the cases of finding common subsequence, it finds the solution in optimum time.

Many researchers have researched about LCS over a period of time. They have given many results. But still it is very complex and there is a huge area left to research on this topic. The time and space needed to solve a problem by using LCS are still high. The main objectives of this research are:

1. To reduce the time complexity and find an optimum a bigger length string.
2. To reduce the space complexity by changing the data structure.
3. To use a new approach (Divide and Conquer) and to see the effects of using this approach.

The remainder of this paper is organized as follows. Section II provides a brief review of related work. In section III, we discuss in detail the proposed algorithm. Section IV contains experimental results and analysis. Finally, we conclude and sketch future research directions in Section V.

II. RELATED RESEARCH

J. Liu and S. Wu show that it is possible to find out the Longest Common Subsequence in linear time using a 2D array [1]. The result lies between in the diagonal line of the two-dimensional array. They used for them theorems provided in [2], [3]. Paper [3] has also shown that the space complexity can be linear in the longest common subsequence. This paper merges two algorithms to reduce the space complexity.

K. Kwarciak and P. Formanowicz propose a DNA sequencing technique using a greedy approach. In their algorithm, the greedy method is applied to two different sequences at the same time. That's why this greedy algorithm is much faster than the dynamic approach. This approach can be used as the longest common subsequence. J. F. Myoupo and D. Semé used a parallel algorithm to minimize time complexity [5]. This algorithm runs in O(logN*logM) which is much smaller than the existing LCS algorithm. In [6], this problem is solved in O(log m*log n) with O(n*m/log m) processors. The CRCW bound is O(log(n(log*log m)2)) time where the processors are O(m*n/log* log m).

In paper [7], X. Tang et al. used a block system by which the process become faster than before. The idea of a B+ tree and O tree is used in this algorithm which has less run time than other algorithms. For that reason, they get a result which takes only 36.5 mm^s. Paper [8] proposes a data-structure that helps to improve the competence of suffix array in the algorithm by storing in external memory model. The authors of this research paper also propose and implement two parallel algorithms (Index Partitioning and

Data Partitioning) on a PC cluster. Here the ASM problem is solved in DNA sequences with the help of suffix array algorithms.

R. L. Goldfeder et al. proposes a system where the DNA sequence/String is divided into some small pieces, and it will be reordered programmatically such that it can enable fast and efficient sequencing for human genomes or for a string [9]. In this paper, they divided the DNA or String sequence in a small portion and get all data and then merged.

Paper [10] presents real-time sequencing and single molecule data that is obtained from a DNA polymerase. DNA polymerase is performed in a continuous template directed fusion using four different fluorescently categorized dNTPs. The data is reported directly used to reveal the distinct polymerization states corresponding to DNA structure. The paper shows 90% accuracy in medical science. F. Chin and C.K. Poon demanded that there has L-matrix on the dynamic approach in LCS [11]. They showed the time complexity becomes O(ns+min(ds, lm)) and the space complexity becomes O(ns+d). They used different data structures to obtain variations of the basic algorithm.

III. The Proposed Algorithm

In the proposed algorithm, the existing Longest Common Subsequence algorithm has just modified by using the queue data structure and the divide-and-conquer method. The existing general LCS algorithm works on $O(MN)$ time. It can be made O(1) if the size of those strings is minimized. Here this idea is used. Let, two string A(A1, A2,….., An) and B(B1, B2,….Bn) are given and C(C1, C2,….., C k) is the sequence of two string. If A >= B, then this algorithm will divide the A string into small parts until the size of the string becomes less than 4. Then these small string and the B string will use in the second process. From the algorithm in Fig. 2the largest string is divided into several small strings (as shown in Fig.3). The small string and the second string are applied in the second algorithm which is given in Fig. 3. The whole algorithm runs in O(n*log(n)) time in the best case. This algorithm takes linear space because of using the queue instead of a two-dimensional array.

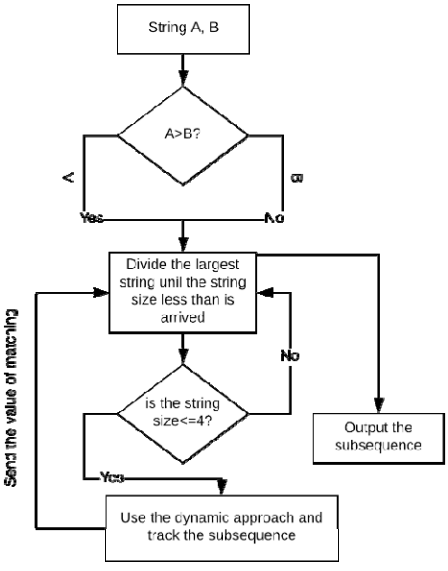

Fig.1 The proposed methodology

From Fig.1, it is clear that there have two steps. The first step is the divide-and-conquer method and the second step is DP.

A. Algorithm

In this algorithm, we have two phases. In the first phase, the large string will be made into a small string by the divide and conquer method. In the algorithm in Fig. 2, the algorithm of the first phase is given.

```
Function making_a_short_string( start , end)
1.  If(start – end <= 4)
2.      return LCS( A[ start … end] , B [ 0 …m])
3.  end
4.  mid = (start+end)/2
5.      return making_a_short_string(start, mid) +
    making_a_short_string(mid+1, end);
End
```

Fig.2 Pseudo code describing the divide-and-conquer method to short the large string

From string A, when the base case arrives in the first phase, it will execute the second algorithm which is given in Fig. 3. From this algorithm, we can get the sequence.

```
Function LCS(s1[ 0…n] , s2[0 …m])
                Bool Array[0…….m)
1.  Declare a queue data structure Q;
2.  matching_number <- 0
3.  for i:= 0 to n
4.    for j:= temporary to m
5.      if i == 0 or j == 0
6.        if i == 0
7.    Q<- 0
8.        End
9.        if j == 0
10.           Q <- 0
11.       End
12.     End
13.     Else
14.       if s1[i-1] == s2[j-1]
15.          diag <- Q.front and pop the front value
16.          previous_value <- diag+1
17.          Q <- previous_value
18.             If prevous_value> matching_number
19.                temporary <- j
20.                Array[j]<- true
21.                Matching_number = temporary
22.                If j == n-1 return Matching_number
23.             End
24.       End
25.       Else
26.     diag <- Q.front
27.          Pop the front value of Q
28.          Vertical_value <- Q.front
29.          Temp = max( previous_value,
    Vertical_value)
30.          Previous_value <- temp
31.          Q <- previous_value
32.       End
```

```
33.        If j == m
34.          Pop the front value of the queue
35.        end
36.        end
37.     end
38.    end
39.    Return matching_number
40.  End
```

Fig. 3 Pseudo Code describing the algorithm of LCS

From this algorithm, we can get an array "Array" which track the sequence. If we iterate through the "Array", we will able to get the longest common subsequence C [0….m] which is "Array".

B. Example

Let Two string A= "abcadbcadadcaaddaddcdcddcdadccdaa .....aaddaada" and B = "abdcad" and C is the sequence where C is equal the size of the min (|A|, |B|). Here B is small so the size of |C| = |B|Here |A|>|B|, so we will divide A into many small strings by algorithm which is shown in the Fig. 4. From the best case of the string, the Strings will go to the next algorithm, where the small string and the new string will go through the algorithm in Fig. 3.

Let the best case string from the algorithm is "abca" and the B string is "abdcad". Then the process will get an LCS between those two strings where the two strings are small so it will run in constant time. Then the subsequence can get by Fig. 3, when i is zero means at the first row of the algorithm, then the queue will be 0 0 0 0 0 0, then the second loop the first element will be zero then the queue will be 0 0 0 0 0 0 0, then if the i-th element and the j-th element is similar then the front value of queue will be incremented and it will be popped out and pushed in the queue, then the queue will be 0 0 0 0 0 1. Then if the i-th and j-th are not similar then it will get from the previous value and the vertical value.

To get the vertical value firstly popped out the first value of the queue then take the new front value. Then compare which is maximum and push it to the queue. Then the queue will be, 0 0 0 0 1 1 by continuing this process after the second-row finishes then the queue will look like 0 1 1 1 1. Here the queue is using, again and again, the first value is popped and the new value is inserted. Lastly, the queue will be 0 1 2 3 4. Then it will return the value 4. During this method, a temporary "Array" is declared which will track the elements which are the subsequence of both strings.

Strings will go to the next algorithm, where the small string and the new string will go through the algorithm in Fig. 3. Let the best case string from the algorithm is "abca" and the B string is "abdcad". Then the process will get an LCS between those two strings where the two strings are small so it will run in constant time. When i is zero means at the first row of the algorithm then the queue will be 0 0 0 0 0 0, then the second loop the first element will be zero then the queue will be 0 0 0 0 0 0 0, then if the i-th element and the j-th element is similar then the front value of queue will be incremented and it will be popped out and pushed in the queue, then the queue will be 0 0 0 0 0 1. Then if the i-th and j-th are not similar then it will get from the previous value and the vertical value. To get the vertical value firstly popped out the first value of the queue then take the new front value. Then compare which is maximum and push it to the queue. Then the queue will be 0 0 0 0 1 1. By continuing this process, after the second-row finish then the queue will look like 0 1 1 1 1.

Here the queue is using again and again, the first value is popped and the new value is inserted. Lastly, the queue will be 0 1 2 3 4. Then it will return the value 4. During this method, a temporary "Array" is declared which will track the elements which are the subsequence of both strings.

IV. Experimental Result & Discussion

The time complexity of this proposed method is n*log(n) and the space complexity is O(n). The process is given in the next sections.

A. Time Complexity

Let, two strings are A[0,….k] and B [0,…..m] and n is the size of min(|A|, |B|). The algorithm has two parts. One is for the divide and conquers method which is recursive and one is a dynamic approach method. Let the time complexity of the dynamic approach is T1(c) and the time complexity of the total algorithm is T(n).

Then, T(n) = T1(c) + 2T(n/2)
= T1(c) + 2{ 2T(n/4) + T1(n/2) }
= 2T1(c) + 4T(n/4)
= 2T1(c) + 4{ 2T(n/8) + T1(n/4) }
= 3T1(c) + 8T(n/8)

= kT1(c) + 2^k T(n/2^k) -------- (i)

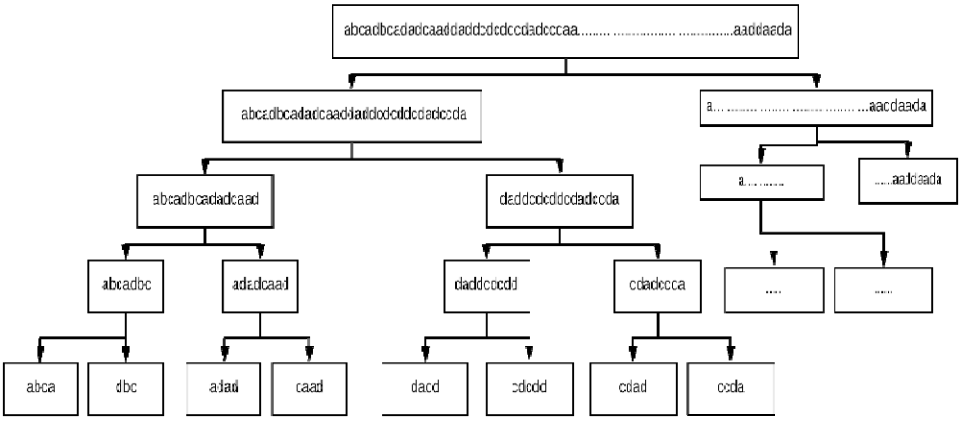

Fig. 4 Divide-and-Conquer method of the largest string

Let, n/2^k = 1

⇨ n = 2^k

⇨ log(n) = k [log base 2]

Substituting k in (i),

T(n) = log(n)T1(c) + n*log(n) -------- (ii)

So, the general time complexity is log(n)T1(c) + n*log(n).The best, worst and the average case is depends on the T1(n) term.

B. Best Case Analysis

From section VI A, the general time complexity is log(n)T1(c) + n*log(n). Let the new sting D and the second string is B. If the new string is the proper subset of the second string (D ⊂ B), then the T1(c) will the constant time. Because all the elements of D are within in B, and the size of the D is less than 4, then the second algorithm will run on constant time. So, T1(c) will be 1.

From equation (ii),T(n) = log(n)*1 + n*log(n)

So, the best case of this algorithm is n*log(n) where n is the size of min (|A|, |B|).

C. Average Case Analysis

The Average case of this algorithm is similar to the best case of the algorithm. Let the new sting D and the second string is B. In the average case, D is the subset of B, means that D has some elements which are in the B. So every recursive method the size of B is reducing, for that reason the algorithm has to go through the size of the B string. The second algorithm will run on linear time. So, T1(c) will be m.

From equation (ii),T(n) = log(n)*m + n*log(n)

So, the best case of this algorithm is k*log(n) where n is the size of min(|A|, |B|) and k is the size of max(|A|, |B|)

D. Worse Case Analysis

The general time complexity is log(n)T1(n) + n*log(n). Let the new sting D and the second string is B. If D' is the proper subset of B means that there has no element in D which is in B. So, it will iterate through all the elements in D so the algorithm will run on O(k*m) where the size of the D is k and the B is m. So, the worst case time complexity will be T(n) = log(n)* k*m + n*log(n) where k is log(n)/2.

Then, T(n) = m*log(n)^2 + n*log(n). So, the worst case of this algorithm is m*log(n)^2, where n is the size of min(|A|, |B|) and m, is the size of max(|B|,|A|).

E. Space Complexity

The space complexity of the first algorithm is O(n/2+1)~ O(n/2) and the space complexity of the second algorithm is O(n) because instead of a 2D array, there is used a data structure queue. The space complexity of queue for the best and worst case is O(n). So the space complexity of the full algorithm is O(n) means that the program is running on a linear space algorithm.

A comparison between our proposed method and the proposed framework of other authors is given in Table 1. From Table 1, it is clearly seen that our algorithm's space complexity is better than any other of these mentioned algorithms and the time complexity becomes a logarithmic function which is optimal than some of the other algorithms.

TABLE I Comparison of time and space complexity

Algorithm	Best time complexity	Average time complexity	Worst time complexity	Space complexity
LCS	Ω(m*n)	Θ(m*n)	O(m*n)	O(m*n)
Ref. [1]	Ω(n*n)	Θ(n*n)	O(n*n)	O(m+n)
Ref. [2]	Ω(n(m-p))	Θ(n(m-p))	O(n*m)	O(m+n)
Ref. [3]	Ω(m*n)	Θ(m*n)	O(m*n)	O(n)
Ref. [11]	Ω(ns+min(ds,lm))	Θ(ns+min(ds,lm))	O(ns+min(ds,lm))	O(n*m)
Our Algorithm	Ω(n*log(n)), n=max(|A|, |B|)	Θ(k*log(n), k=max(|A|, |B|)	m*log(n)^2 + n*log(n), m=max(|A|, |B|), n=max(|A|, |B|)	O(n)

TABLE II Comparison of time with General LCS algorithm

Length of two string (n and m)	LCS(sec)	Our Algorithm (sec)
n<100 && m<100	0.932	0.812
n<10000 && m<10000	3.003	2.855

In this paper, the space complexity of LCS is highlighted. The space complexity of this algorithm is linear. The best space complexity of queue is O(n) as well as the space complexity is O(n). Divide-conquer approach has been used here. For this approach, this will take constant time to solve a problem. Later the data structure has been changed from a two-dimensional array to queue. For this, space will be reduced. In Table II it has shown time comparison between general LCS and our algorithm.

Generally, for LCS, the worst time complexity becomes exponential and it becomes very complex to find a subsequence from a very large string. But in the proposed case of this paper, the worst time complexity is O(m*((log n)^2)) for which it becomes very optimal to get the final result from a very large string. But not for only the worst case, In the time complexity for best case in the proposed LCS is O(n*log(n)). It is very optimum and time-consuming to get the final result.

V. CONCLUSION

The LCS algorithm is studied and researched by a lot of researchers. Here, we have developed an algorithm by using a divide and conquer approach and a queue. By using this approach we have made the space complexity linear O(n). The time complexity becomes a function of the logarithm. For the best case, it becomes O(n*log(n)) where n is the length of the smallest string between the two string. For average time complexity, it becomes O(k*log(n)) where k is the length of the largest string between the two string. For the worst case, the time complexity is O(m*log^2(n)) where m is the length of the bigger string. Normally the time complexity for the general LCS algorithm over the world is

O (n^2). We are able to show that our algorithm is better which gives results faster and use linear space than the used algorithm.

***Abstract*— Wind power prediction is necessary for proficiency assessment of a potential wind site and can improve the technical and economic integration of wind energy into the existing electricity grid. The aim of the study is to compare the analysis of the wind power prediction between Kuala Lumpur and Melaka in Malaysia for potential place selection of wind power generation. Field data are collected from two places in Malaysia over a period of three years each place from December 2013 to December 2015. The model has been developed by an Adaptive Neuro-Fuzzy Interface System (ANFIS). In addition, the effectiveness of soft computing ANFIS is applied to the wind power prediction model. It involves four input variable-temperature, humidity, pressure and wind speed and output variable wind power has done using MATLAB. The predicted wind power by these sites are compared with the measured data of Meteorological Department of Malaysia. The proposed predicted model of ANFIS is clearly indicated high capability and reliability based on error values of estimated wind power. Therefore, ANFIS model has been shown excellent results in the analysis the root means square error (RMSE), mean absolute error (MAE), mean absolute percentage error (MAPE) and coefficient of determination (R^2).**

Keywords— Adaptive Neuro-Fuzzy Interface System (ANFIS), Wind power and prediction

I. INTRODUCTION

For the past few decades, the demands of energy have been gradually increasing, especially for electrical power and environmental issues and this has become a challenging issue for the world. Furthermore, pollution is growing parallel with the energy demand while sources of conventional energy such as fossil fuels are rapidly depleting. Over the last few decades, researchers have been conducting studies to improve the energy efficiency [1] [2]. Wind power has been used for nearly three thousand years. At the early twentieth century, the power of wind was used to deliver mechanical power to pump water and electricity [3]. Wind turbine is a device that produces the potential winds and converted to electrical energy [4]. The wind power plant is established in desolate areas whereas weather condition is harsh [5]. Basically, there are various types of wind turbines exist in this world but horizontal axis wind turbine (HAWT) and vertical axis wind turbine (VAWT) are the most common and widely implemented wind turbines

Economic development of a county depends on the energy. Fossil fuels cannot be contributed to fill up world energy demand. Some of developing countries are still under stress for energy shortage for fossil fuel has limitation for usage [6]. In addition, it has more negate environment impact to compare renewable energy. Alternatively, renewable energies are playing a role model to achieve energy demand in the World which has less environment impact.

Wind energy is a renewable energy which is produced by wind blowing by captured wind turbine. Wind turbine converted to mechanical energy into electrical energy. Some of countries namely Denmark, Germany, Spain, United Sates and India are producing electrical from wind energy [7]. Site selection for wind turbine installation is essential to produce maximum wind energy. In addition, the accurate wind power and wind speed prediction would be profitable for operation. There are several mathematical models suggested for wind power prediction. They have some difficulties namely higher calculation time required. On the other hand, soft computing techniques are provided better advantages including no required knowledge of internal systems parameters, compact solution for multi-variable problems and fast calculation. Recently, some researchers have successfully worked in the wind energy.

The crisis of energy is the changing for the researcher. For the overcome this crisis, researchers are concentrated to the renewable energy such as wind, solar, rain, tides, waves, and geothermal heat energy for power generation as alternate natural sources. Wind power can be used for power generation where availability of wind speed is existing. There are various European countries to start power generation using wind speed. The nature of wind speed is fluctuating so the small change of wind speed can be affected to wind power generation. The site selection is very crucial issue for wind power generations. Before wind turbine installation in wind farm, the wind speed prediction is very important criteria for site selection [8, 9].

Wind power prediction can be classified input variables and time series. In this study, input variables are considered for prediction. During operation condition of wind turbine can be controlled with millisecond to second by wind speed prediction [10, 11]. Mainly there are two types of methods those are used for prediction purpose namely physical and

statistical. The outcome of the statistical method is to build up a relationship with wind power forecast and measured data of historical time series which can be helped for site selection of wind farm installation [12]. On the other hand, physical method tries to find wind power output by considering some variable namely environment temperature, local terrain and numerical weather [13, 14].

There are several statistical methods such as Autoregressive Moving Average (ARMA), persistence model and Kalman filter [15]. In Addition, for historical time series employed by the artificial intelligences namely radial basis function neural network (RBFNN), backpropagation neural network, support vector machine (SVM), nonlinear autoregressive neural networks (NARNN) and adaptive neuro-fuzzy inference (ANFIS) [16] [17]. In this study, ANFIS employed for wind power prediction two different area namely Kuala Lampur and Melaka in Malaysia. The proposed ANFIS is tested on a case study real data from metrology department in Malaysia.

The layout of the paper is as follows. Power of wind turbine is presented in section II. ANFIS is described in section III. Results and discussion are displayed in section IV. Finally, the conclusion of this paper is presented in section V.

II. Power Of Wind Turbine

The wind power has achieved advanced efficiency due to the modern technology. Since the 1980, the structural dynamics, aerodynamics and micrometeorology have contributed to an increase about 5% yearly [18]. The heavy weight and noise of wind turbines are accountable for the low power output. The higher power generation of the wind turbine not only depends on an electric generator and high-capacity machine but also on faster computer base techniques [19]. For HAWTs, most of the researchers make an analysis on the HAWT performance with respect to aerodynamic characteristics of the blades for the power generating. Authors are not concentrated on the self-stating of HAWT because it depends solely on the wind turbine speed [4]. The conversion of wind power system is included Wind speed is the major factor for wind power production. Wind power could be generated from wind turbine by capturing wind speed though blades of wind turbine. Slightly change of wind speed which is directly influence to the wind power in order to the relation between wind power is directly proportional to the cube of wind speed. The wind power captured by rotor blade of wind turbine which can be expressed by [8].

$$P = 0.5\rho A C_p v^3 \tag{1}$$

Where, ρ is the density which is constant at hub height, swept area of the blades A, v is the wind speed and C_p is the power coefficient which means the percentages of wind power captured by wind turbine blades which depends on the pitch angle β of the blades and tip-speed ratio λ .

III. Adaptive Neuro-fuzzy Inference System

ANFIS is a system that is used for different purposes to classify, and to identify the chaotic time series. Besides that, ANFIS also works to generate input –output pairs as the basis of fuzzy 'if-then' rules construction by membership function and it also takes FIS system for tuning with the help of back propagation algorithm. The FIS has three components: rule base, database and reasoning mechanism. These systems show best performance like human expertise to recognize a specific domain [20]. In ANFIS, recognition of pattern and implementation in environment can done through neural network. To observe and verification of the model, half of the training date have to be used while others half would be used for testing purposes [21]. Therefore, ANIFS can accurately determine wind power prediction with the help of training phenomena as well filtered data. The first layer, which have two input variables, input 1 and input 2 for the purpose to give input value for the next layer. Every node in this layer has an adaptive node. The 'IF THEN' rules of Takgi and Sugeno's class of fuzzy logic with two inputs for the first order Sugeno are employed for the purpose of this study [22, 23].

If x is P and y is R, then

$$f_1 = p_1 x + q_1 y + r_1 \tag{2}$$

Each MFs weight can be checked through the second layer. In this layer, every node is non-adaptive which would multiply the input signals. The MFs layer refers as multiplier to receive to signal and send out the outcome in $w_i = \mu_{PQ}(x) * \mu_{PQ}(y)$ form

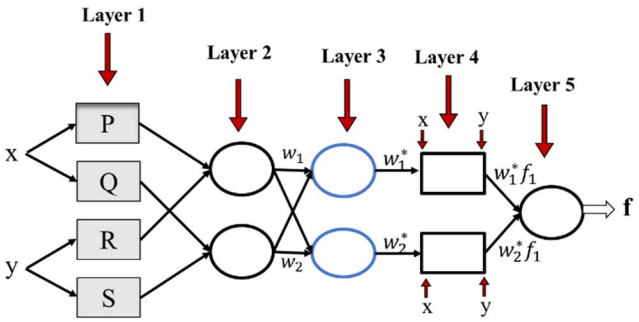
In the next layer, third one, is called rule layer. In the layer pre-condition of the fuzzy rules matching can be done by each node. Fuzzy rules and layer numbers are in equal number. Outcome of this layer is generally called normalized firing strengths.

$$(x) = tri(x; p_i, q_i, r_i) = \begin{Bmatrix} 0, & x \le p_i \\ \frac{x-p_i}{q_i-p_i} & p_i \le x \le p_i \\ \frac{r_i-x}{r_i-q_i}, & q_i \le x \le r_i \\ 0, & r_i \le\le x \end{Bmatrix} \tag{3}$$

The layer, defuzzification, can provides output values by inference of rules. In this layer, every node is an adaptive node function $0_i^4 = w_i^* xf = w_i^*(p_i x + q_i y + r_i)$ where the input variables are $\{p_i, q_i, r_i\}$.

$$0_i^5 = \sum_i w_i^* xf = \frac{\sum_i w_i f}{\sum_i w_i} \tag{4}$$

The last layer is called output layer that can to sum all the incoming inputs (coming from fourth layer) and to transform them. In addition, the fuzzy classification outputs converted by this layer. The structure of ANFIS is shown in Fig. 1.



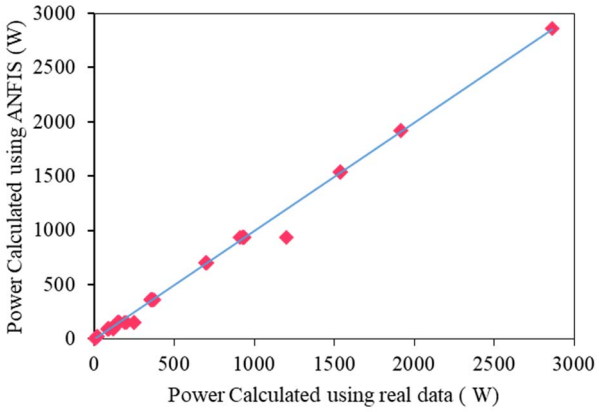


Fig. 1: The structure of ANFIS.

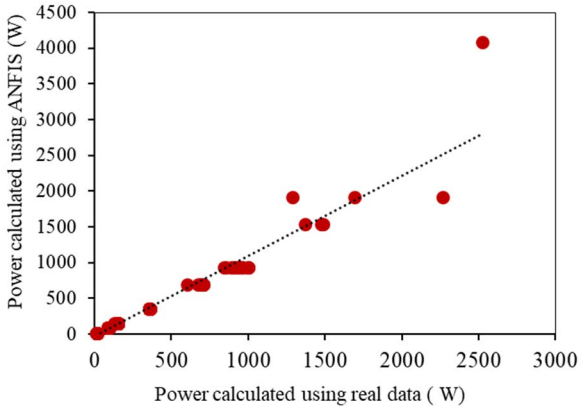

IV. Results and Discussion

To predict yearly wind power a model is developed by ANFIS methodology which is shown in this study. To develop the proficiency of ANFIS model; the comparison of wind power prediction at Kuala Lumpur and Melaka approaches have compared. As input parameters the temperature, wind speed, humidity and pressure data collected from the Metrology Department of Malaysia the wind power is used for first step analysis. These wind power values were calculated using the Equation (1). Those wind power values which were attained from both methods; were gathered and defined as training and testing data. To achieve this aim, firstly, three years averaged measured wind power data were used and divided to training phase (two years) and testing phase (one year). To estimate the wind power, at first the ANFIS network was trained with the extracted wind power data. The amount of wind power should estimate by the ANFIS network. To fuzzily the ANFIS inputs; three bell-shaped member ship functions were used. When the training period is finished then the remaining data set is used for testing the ANFIS network.

Fig. 2 shows scatterplot wind power values via the predicted wind power values against ANFIS model used measured data of Kuala Lumpur. Fig. 2(a) showed the results for the training data phase of wind power, whereas Fig. 2(b) stipulated the results for the testing phase. Evidently, most of the points fall along the diagonal line in training phase as well as in testing phase with slightly distinction; which concluded a suitable level of agreement between the estimated values by ANFIS technique and those obtained using measured data. According to the Fig. 2(a) and (b), as expected, the dispersion degree of the testing phase is slighter compared to the training phase. Similarly, in Fig. 3, scatterplots were showed the predicted wind power values via the determined wind power values against ANFIS model used measured data of Melaka. Moreover, Fig. 3(a) presented the results for the training phase, whereas Fig. 3(b) indicated the results for the testing phase of Melaka respectively.

(b)

Fig. 3. Scatter plot of the wind power values based on measured data versus estimated ones via ANFIS for:(a) training data set and (b) testing data set at Melaka

Fig. 4 and Fig 5 display the measured and predicted wind power data of Kuala Lumpur and Melaka respectively. From the Fig. 4, the predicted is almost near to the measured wind power. Moreover, based on the indicators, the predicted wind power data is very close to measured data those predicted and measured data set evaluated by ANFIS. It can be concluded by above discussion, the performance of ANFIS shows the better result at Kuala Lumpur area to compare the Melaka area to based on the Table 1.

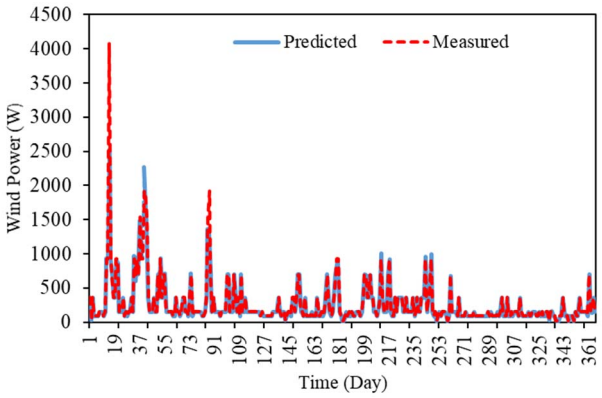

Fig. 4: Predicted data from testing ANFIS and real data of Kuala Lumpur.

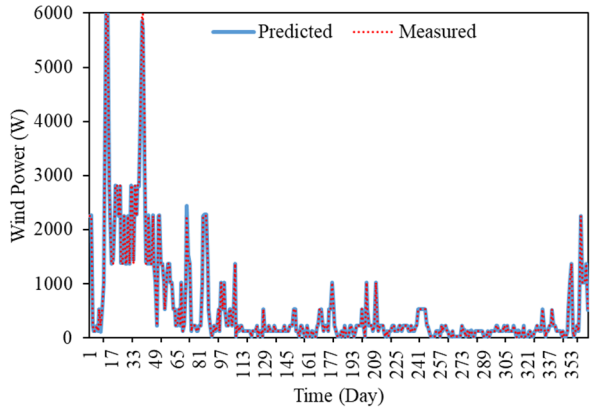

Fig. 5: Predicted data from testing ANFIS and Measured data of Melaka

TABLE I: PERFORMANCE OF PROPOSED ANFIS MODEL FOR WIND POWER PREDICTION USING FOUR INDICATORS

Model	Location	Training			
		RMSE	MAE	MAPE	R^2
ANFIS	KL	2.68	2.13	11.36	0.985
	Melaka	2.92	2.35	13.95	0.973
		Testing			
		RMSE	MAE	MAPE	R^2
	KL	1.65	1.87	12.35	0.968
	Melaka	1.82	1.98	13.23	0.944

Table 1 illustrations the four performance indicators which are evaluated the performance of ANFIS model for wind power prediction in Kuala Lumpur and Melaka at both training and testing stage. At training, performance of ANFIS model for Kuala Lumpur (RMSE=2.68, MAE=2.13, MAPE 11.36 and $R^2 = 0.985$) shows the slightly better than Melaka (RMSE=2.92, MAE=2.35, MAPE=12.95 and $R^2 = 0.973$). In addition, at testing stage, the accuracy of ANFIS model for wind power prediction in Kuala Lumpur shows satisfactory results comparison to the Melaka based on the performance indicators in shown in Table 1. According to the Table and above-mentioned discussion, it can be concluded that the ANFIS model enjoys high capability to predict daily wind power in Kuala Lumpur.

V. CONCLUTION

The reliable and accurate wind resources assessment is play and important role for harnessing wind power. In addition, the precise of wind power prediction is key parameter for wind turbine or wind farm installation. In this research Soft computing ANFIS model predict monthly wind power at Kuala Lumpur and Melaka areas in Malaysia. ANFIS model simulated in MATLAB. The outcome of this study shows that ANFIS model is more efficient at Kuala Lumpur to compare Melaka based on the performance indicator namely RMSE MAE, MAPE and R^2 from Table 1. The achieve results obeyed that the ANFIS model is the more capable the predicting wind power with favorable reliability and accuracy.

***Abstract*— In grid connected renewable energy generation system, using converter is a must. For this purpose, we proposed a multilevel H-bridge inverter that will contain lower third harmonic distortion. To achieve this target, higher number of output voltage level is necessary. Space Vector Pulse Wide Modulation (SVPWM) technique is very much efficient and relevant to our need because of its good utilization of dc bus voltage and reduced switching frequency here we implemented this technique. Using MATLAB/Simulink we achieved seventeen, twenty five and forty seven level of output voltage. We compared THD among them and found that THD was decreasing when output voltage level was increased. Finally THD below five percent could be achieved.**

Keywords- Multilevel Inverter, Dwell time, Cascaded H-Bridge Inverter, Space Vector Pulse Width Modulation (SVPWM), Third Harmonic Distortion(THD).

I. Introduction

Recently, there is a huge development and enhancement in the field of renewable energy[1]. Now-a-days in the developed countries renewable energy is one of the most expanding sector for power generation. All around the world lots of renewable energy plant has been established. Renewable energy requires dealing with DC-AC conversion. DC-AC conversion requires an inverter. With the development of semiconductor devices in recent times, we can develop highly efficient multilevel inverter[2][3] for conversion of DC into AC. There are a number of topologies and modulation techniques[4] which are being used in an inverter. The most commonly used topology is H-bridge topology and the most commonly used modulation techniques are Pulse Width Modulation (PWM) and Space Vector Modulation (SVM)[2][3][4]/ Space Vector Pulse Width Modulation(SVPWM)[5].In our proposal we used H-bridge as topology and modulation technique is Space Vector Pulse Width Modulation(SVPWM).SVM is one of the most complex method in both mathematical analysis and to implement in control circuit as well. The entire modulation process depends on three factors which are- voltage space vectors, transformation of a three phase time dependent system into a two co-ordinate time invariant system and effective pulse width modulation (PWM) which results in gate pulse generation. In spite of these complexity SVM is very much efficient and also gives better output.

II. Proposed Inverter

A. H-Bridge

In the field of research of power electronics multilevel inverters are of greater interest. Multilevel inverters are the most important technology for controlling high voltage and it also controls power distribution and power quality. The general structure of the multilevel converter is to synthesize a near sinusoidal which is actually a multilevel stair case like structure attained from a dc voltage to convert it into a perfect sinusoidal wave which is the required AC output. As more steps are added to the waveform, total harmonic distortion of the output wave decreases and it approaches zero as the number of levels increases. A cascaded multilevel inverter consists of a series of H-bridge inverter units. A H-Bridge inverter is available for both single phase and three phase conversion. In our proposal we used three phase topology for DC-AC conversion.

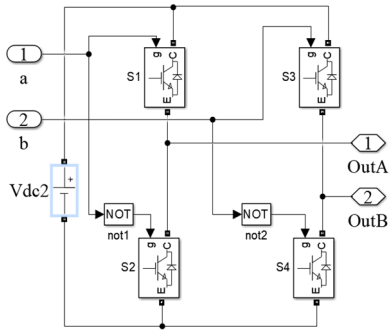

Figure1: H-Bridge circuit

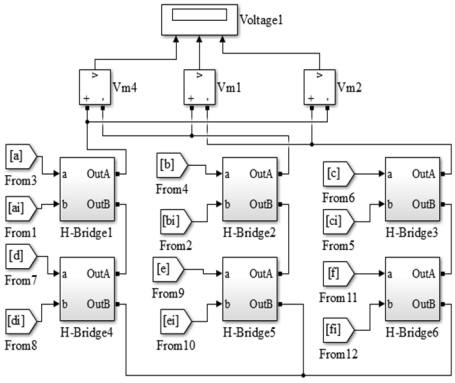

Figure2: Multilevel H-Bridge for 5 level output

As semiconductor device, we used MOSFET for switching with respect to gate impulse given by the controller circuit[6]. For multilevel output we cascaded[7] a number of H-bridge circuit For increasing the level we need to add H-bridges with the circuit. The equation is quite like number of levels = (2H+1); where H= number of bridges. Higher the levels higher the efficiency in output and higher is the number of H-bridges needed to be cascaded.

B. Modulation Technique

In electronics and telecommunication, modulation is a process which changes or modifies a particular property of the signal with help of a modulating signal. But in power electronics this modulation means the way or the process of controlling the on/off of gate devices to control the voltage output of the inverter as well as the harmonics of the inverter output as well. There are many types of modulation and some of them are highly efficient and advantageous in particular sectors of converter technology.The main aim of all these modulation techniques in inverter technology is to shape the output approximately similar to a sine wave. The quality of the modulation techniques are justified by the amplitude of the output, the harmonic contents, switching loss, effect of harmonics on the source, controllability etc. In case of hardware implementation the semiconductor devices and oscillators play a vital role. In our proposal we used Space Vector Modulation (SVM)/Space Vector Pulse Width Modulation (SVPWM) because of its efficient use of dc supply voltage, high number of level generation, low harmonic content and lower total harmonic distortion(THD).

C. SVM/SVPWM

The space vector PWM (SVM)[8] method is an advanced computation-intensive PWM method and is possibly the best method among the all PWM techniques for variable frequency drive application. Because of its superior performance characteristics, it has been finding wide spread application in recent years. Again this process has wide applications in motors [12], three-phase AC machines [13], electrical vehicles[14],solar PV cells[15]etc.In the Space Vector Pulse Width Modulation(SVPWM) technique, the duty cycles are computed rather than derived through comparison as in Sine Pulse Width Modulation. Each sector covers an area of 60 degree. In this process the sinusoidal voltage is treated as a constant amplitude vector rotating at constant frequency. Then the three phases are transformed into two axis or in other words it can be said that three-phase voltage vector is transformed into a vector in the stationary d-q coordinate frame which represents the spatial vector sum of the three-phase voltage. This PWM technique approximates thereference voltage V_{ref} by a combination of the eights witching patterns ($V_0$to V_7)[9]. The vectors ($V_1$to V_6) divide the plane into six sectors. The reference voltage is synthesized by using the nearest two neighboring non-zero vectors and zero vectors. The choice of the non-zero vectors depends upon the sector number in which the reference is located. Once the reference voltage is located, the vectors to beused for the SVM implementation to be identified. The

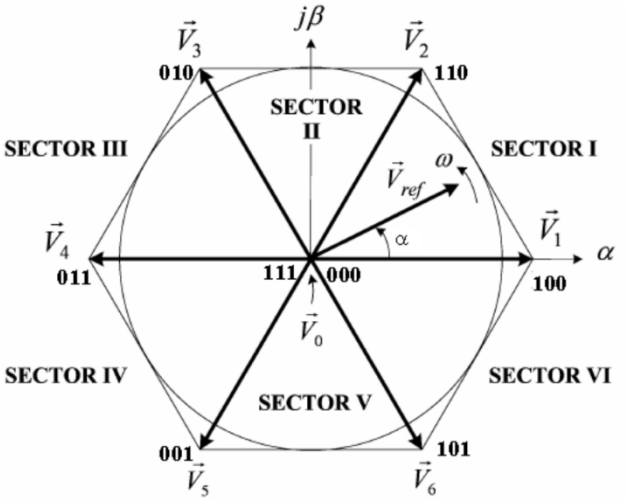

Figure 3: Space Vector Diagram

next task is to find the time of application of each vector which is called the dwell time. The output voltage frequency of the inverter is the same as that of the speed of the reference voltage and the output voltage magnitude is the same as the reference voltage.

D. Working Mechanism

In this paper, classical 2-level space vector technique has been used for calculation of on-time.Space vector diagram is a hexagon, consists of six sectors.Let's consider 3-phase sinusoidal voltage components are [10]

$$V_a=A\sin\omega t \quad \ldots\ldots\ldots\

If, $180 < \theta \leq 240$, sector =4

If, $240 < \theta \leq 300$, sector =5

If, $300 < \theta \leq 360$, sector =6

Then for each sector, we introduce a new angle γ

If, sector=1, $\gamma = \theta$

If, sector=2, $\gamma = \theta - \frac{pi}{3}$

If, sector=3, $\gamma = \theta - \frac{2pi}{3}$

If, sector=4, $\gamma = \theta + pi$

If, sector=5, $\gamma = \theta + \frac{2pi}{3}$

If, sector=6, $\gamma = \theta + \frac{pi}{3}$

Here let us consider, sampling period T_s and modulation index is denoted by a. So we find dwell time,

$$T_1 = T_s a \sin\left(\frac{pi}{3} - \gamma\right) \dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots (7)$$

$$T_2 = T_s a \sin(\gamma) \dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots (8)$$

$$T_0 = T_s - T_1 - T_2 \dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots (9)$$

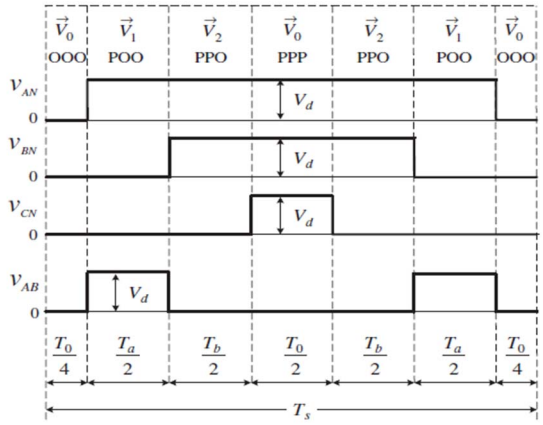

Figure 4: Segment switching sequence for $\overrightarrow{V_{ref}}$ in sector 1.

Table-1: Seven segment switching sequence for six sector

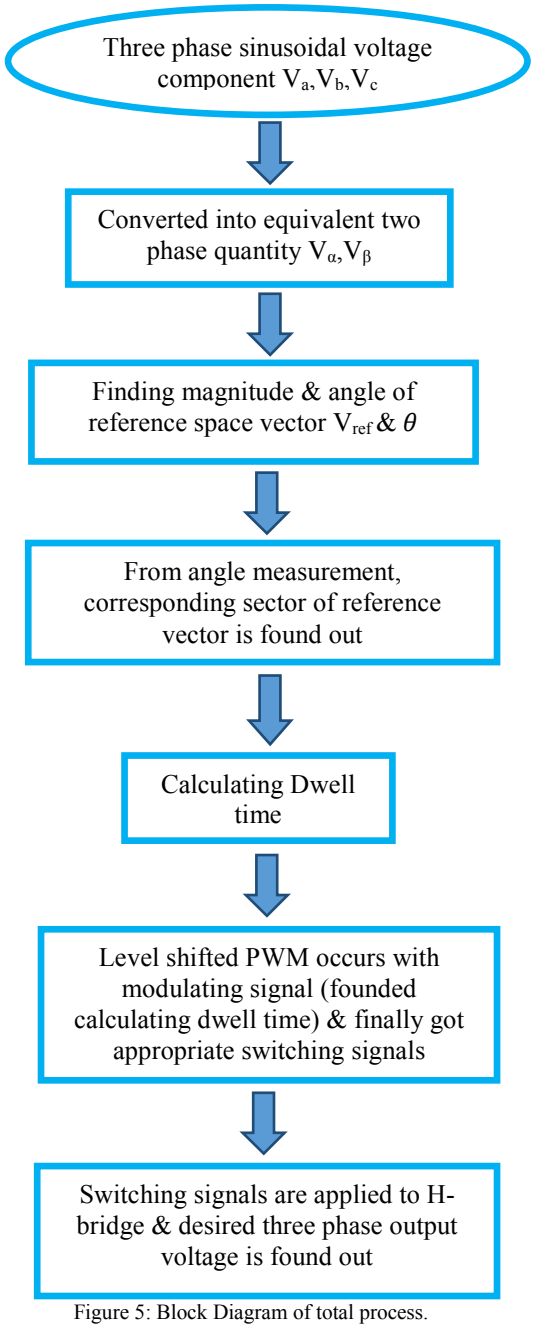
Sector	Switching Segments						
	1	2	3	4	5	6	7
I.	$\vec{V}_0$	$\vec{V}_1$	$\vec{V}_2$	$\vec{V}_0$	$\vec{V}_2$	$\vec{V}_1$	$\vec{V}_0$
	000	100	110	111	110	100	000
II.	$\vec{V}_0$	$\vec{V}_3$	$\vec{V}_2$	$\vec{V}_0$	$\vec{V}_2$	$\vec{V}_3$	$\vec{V}_0$
	000	010	110	111	110	010	000
III.	$\vec{V}_0$	$\vec{V}_3$	$\vec{V}_4$	$\vec{V}_0$	$\vec{V}_4$	$\vec{V}_3$	$\vec{V}_0$
	000	010	011	111	011	010	000
IV.	$\vec{V}_0$	$\vec{V}_5$	$\vec{V}_4$	$\vec{V}_0$	$\vec{V}_4$	$\vec{V}_5$	$\vec{V}_0$
	000	001	011	111	011	001	000
V.	$\vec{V}_0$	$\vec{V}_5$	$\vec{V}_6$	$\vec{V}_0$	$\vec{V}_4$	$\vec{V}_6$	$\vec{V}_0$
	000	001	101	111	101	001	000
VI.	$\vec{V}_0$	$\vec{V}_1$	$\vec{V}_6$	$\vec{V}_0$	$\vec{V}_6$	$\vec{V}_1$	$\vec{V}_0$
	000	100	101	111	101	100	000

After calculating dwell time, next step is to arrange switching sequence. Switching sequence must satisfy following two requirement to minimize device switching frequency.

1.The transition from one switching state to the next involves only two switches in the same H-bridge, one being switched on,and the other switched off

2. The transition of $\overrightarrow{V_{ref}}$ moving from one sector to another requires no or minimum number of switching.[11]

Here, even segment switching sequence for (V_{ref}) in sector 1 is shown in Figure 4. For all 6 sectors of space vector diagram, we find the switching sequence as figure 5. Using these switching sequences, 3 switching signals are found. Then these switching signals are considered as modulating signal and 8 carrier signals are taken .The carrier signals are triangular signal. A level shifted PWM [16][17] was performed between switching signal and carrier signals



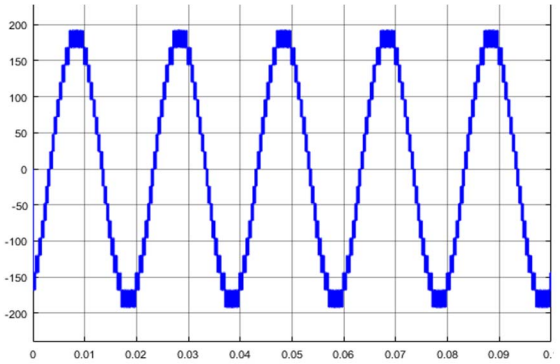


Figure 5: Block Diagram of total process.

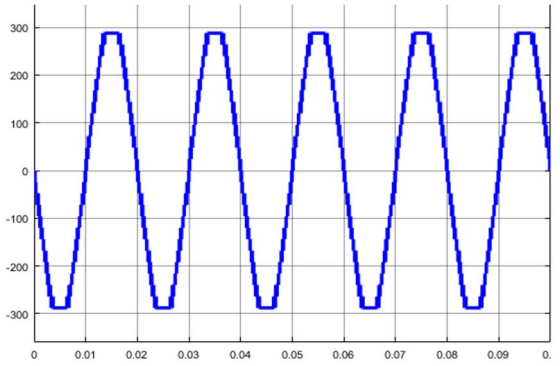
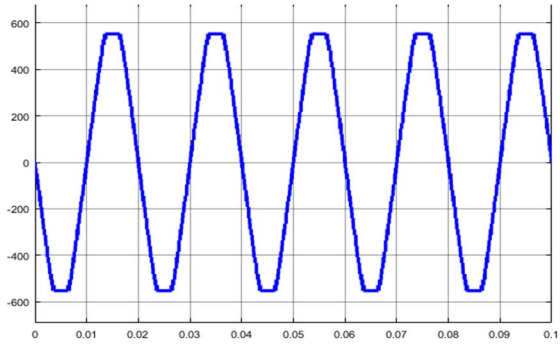
and final output switching signals were found out .These final switching signals are applied to H-bridge MOSFET's gate.



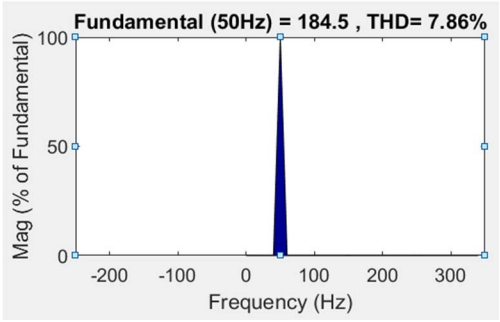
In cascaded H-Bridge Inverter, number of voltage level is denoted as m=2H+1,where H is number of H Bridge .As we cascaded 8, 12 & 23 H-bridge in each phase, so respectively. 17,25 & 47 level phase to phase output voltage could be achieved.

III. Simulation Result

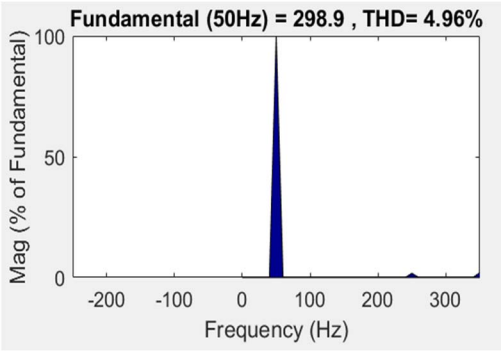


Simulation was performed using MATLAB/Simulink[18] to achieve 17,25 & 47 levels output voltage. In fig 6,output voltage curve and in fig 7,THD spectra has been shown. In table 1, comparison of THD between these 3 output has been shown. It has been seen that THD decreases with increase of number of output voltage levels.

(a)



(b)



(c)

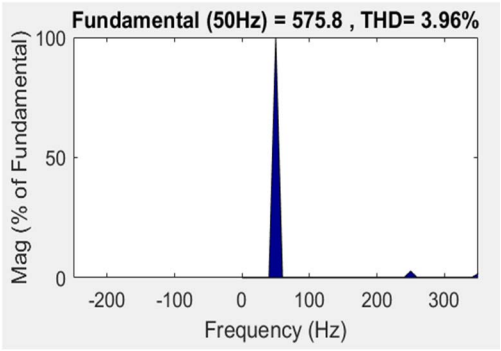


Figure 6: Phase to phase output voltage (a) output voltage for 17 level (b) output voltage for 25 levels (c) output voltage for 47 levels

(a)

(b)

(c)

Figure 7: Spectrum Analysis Graph of Cascaded H Bridge invertor (a) spectral analysis for 17 level output (b) spectral analysis for 25 level output (c) spectral analysis for 47 level output.

Table-2: Third Harmonic Distortion for different output level

Number of Levels	THD
17	7.86%
25	4.96%
47	3.96%

Here, it is seen that for increasing number of levels we get lower total harmonic distortion. That is as the number of levels are increased output becomes more efficient and perfect as expected.

IV. Conclusion

Here we proposed several designs including 17, 25 and 47 level Multilevel H-bridge inverter using SVPWM.We analyzed third harmonic distortion (THD) and found that it decreases with number of level increases. Though we can simulate higher level in Simulink but in hardware implementation we may face some complexity. Due to switching losses increases with increase in level, desired output may be distorted. Renewable energy is getting popular day by day. As here we find desired output voltage and low THD as well as higher efficiency. So in case of renewable energy, we will be much more benefited.

Abstract*— The ever-growing problem which is threatening the current mailing system is spam. Spam is nothing but an unsolicited bulk e-mail frequently sent in a financial nature which generates the need for creating an anti-spam filter. Amongst many spam filtering techniques, the most advanced method "Naïve Bayesian filtering" using the Support Vector Machine (SVM) have been implemented. Spammers are very careful about the filtering techniques. For that very reason, dynamic filtering is needed and the proposed method meets the demand. The algorithm splits the received email into tokens and uses Bayes' theorem of probability to calculate the probability of spam for each token to determine the total spam probability of the mail. Implementation of SVM instead of corpora is one of the added features of the algorithm. The most challenging feature was to take the words as well as whole sentences as input in the SVM as tokens and feature vectors. The inclusion of sentences in the dataset training has increased the accuracy of detecting spam and ham. Natural Language Tool Kit (NLTK) has been used as a useful language processing tool to tokenize the sentences and also to understand the meaning of the same types of sentences to some extent. As a test mail is being compared by word to word and also sentence to sentence from the training datasets to determine if the mail is spam or not, it will improve the performance of the filter. With some simple modifications, the filter can be used in both server and client end. The efficiency increases gradually with the increased number of email it processes.

Keywords- Spam, Bayesian Approach, SVM, Tokenization, Spamicity, Dataset.

I. INTRODUCTION

The internet and E-mail become major communication media in every aspect of our life, they have revolutionized the way of doing business and socializing. The Internet has made information gathering and publishing easy and provided the convenience of online shopping and financial management. However, these new technologies have created new issues and problems at the same time. Among the issues, the so-called 'spam' is the major puzzle.

The word "Spam" as applied to email means Unsolicited Bulk Email (UBE). It can be said in another way that the recipient has not any granted way to detect the sender of mail containing a large collection of messages. Some people may include the e-mail produced by mass-mailing viruses or Trojan horses as spam.

The manifestation of spam has become a fundamental problem for internet user in general. The recipients of bulk emails get puzzled while differentiating the important mail from spam. It also reduces the efficiency of a company and somewhat more. Apart from direct losses, indirect losses are made as well as consumption of storage, internet bandwidth and so on. Some folks even predict that the arrival of spam will bring about the end of e-mail entirely.

Dealing with the issues, numbers of spam detection and filtering methods have been developed. These techniques are effective in some degrees but not limitation free. Signature-based filtering is accurate and fast but applicable for particular emails. On the contrary, the Learning-based system is slower. Above techniques are based on pattern matching rules. Most often it requires tuning for each user's messages which is time-consuming and difficult. Furthermore, the spammers are very aware of the spam detection techniques and try to overlook the techniques variously. An automated learning system that would able to separate the legitimate message is highly suggested.

This paper examines and implements the cutting edge anti-spam technique 'Naïve Bayesian filtering' using Support Vector Machine (SVM) which is learning based dynamic solution. It can adapt to the new techniques of spammers by enriching the trained dataset.

II. RELATED WORK

The naïve Bayesian spam filter is a member of the Learning-based spam filter family. At the very beginning,

Pantel and Lin developed a spam filtering technique based on text classification [1]. Afterward, many scientists and researchers worked on Bayesian spam filtering [2]. Paul Graham proposed a modified algorithm with a large dataset in 2003 and be able to extend the accuracy rate and minimize the probability of false positive significantly [3]. The experiment of Pantel and Lin showed their success rate is 92% with 1.16% false positive. On the other hand, Paul's algorithm was able to detect 99.5% spam with 0.03% false positive. Paul claimed that the main reason behind it was working with a large number of dataset.

Biju Issac and Wendy J. Jap developed a system using Porter's stemmer algorithm along with Bayes theorem. They used porter's stemmer algorithm to split every keyword to its stem which improved the efficiency. Because it reduced the keywords to be searched and developed the margin of accuracy. [4]

Lin Li & Chi Li also implemented a system based on the Naïve Bayesian spam filter. They use the TF-IDF method for more accuracy [5].

Spam detection with K-means clustering algorithm can also be used to detect spams. It also provides a promising result [6].

Naïve Bayes is a strong tool for spam filtering. There are several forms of Naïve Bayes which gives different accuracy [7].

In some cases, unsupervised learning provides more accurate result and it is best suited [8]. Another most recent technique is deep learning. Researchers are also trying to deploy a technique based on deep learning in spam detection [9].

Although all of the solutions discussed and implemented above are effective to some degree, each of the processes has limitations too. None of the solutions can provide 100% accuracy, and there's always a percentage of false positive. No single method is enough to detect and filter spam because spammers are very much aware of the modern spam detection techniques and they are smart enough to circumvent a spam filter. For this reason, a "cocktail" approach is used to detect spam successfully. Combination of the strength of each system may provide a robust solution in case of spam detection.

III. PRELIMINARIES

A. Various Spam Filtering Techniques

Spammers are very conscious of spam filtering techniques. They try their best to overlook existing spam filtering techniques. For meeting up the demand, over the years many filtering techniques have been introduced for filtering spam emails. Signature-based, rule-based and learning-based filtering are some of them.

- In the signature-based filtering, the hash code of known spam is stored in the database. If an incoming email's signature is matched with the stored signature, then the incoming mail is said to be spam. The process is extremely accurate, but it can't detect a new technique of spam.
- The rule-based filter uses a list of keywords; these keywords are the spam keywords. If an incoming mail contains these keywords, then it is considered as spam. The keywords are stored in the database. These filters have high false positive and negative rates. It's because of specific words.
- In learning-based filtering, the filter is trained by itself from time to time according to its input. This approach is a dynamic one. As the spammers are being more conscious of the conventional spam filtering techniques, learning based filtering is the best solution for it.

Through the experiment Bayesian spam filter is used which is one of the learning based spam filters. This system tokenizes the received mail and compares them with the tokens stored in the database. It requires an initial training period. Throughout the training period, the Bayesian filter supervises the incoming and outgoing email and started to create a dataset for the mail flow. System administrators may also tweak the database to better train the Bayesian engine.

B. Bayes' Theorem in Spam Filtering

Computing conditional probabilities, Bayes' formula is one of the famous formulae. Generalized Bayes' formula:

$$P(B_1|A) = \frac{P(B_1 \cap A)}{P(A)} = \frac{P(B_1)P(A|B_1)}{\sum_{i=1}^{n} P(B_i)P(A|B_i)} \quad (1)$$

Where,

- $P(B_1|A)$ is a conditional probability that indicates occurring $P(B_1)$ given that P(A) is true.
- $P(A|B_1)$is also a conditional probability that indicates the probability of occurring P(A)given that $P(B_1)$ is true.

B. Naïve Bayes' Formula in Spam Filtering

Bayesian email filters are based on Bayes' theorem (1). The theorem is most often used in the field of spam detection.

Naïve Bayes' theorem is given below which is used to calculate the spam probability of the system.

$$P_r(S|W) = \frac{P_r(W|S).P_r(S)}{P_r(W|S).P_r(S) + P_r(W|H).P_r(H)} \quad (2)$$

Where,

- Pr(S|W) denotes the probability of spam message when the spam detecting word is in it.
- Pr(S) denotes the overall probability of spam message.
- Pr(W|S) denotes the probability of spam word in the spam messages.
- Pr(H) denotes the overall probability of spam message
- Pr(W|H) denotes the probability of spam word in the ham messages.

Initially when the mail received it is assumed that the mail is neither spam nor ham i.e., the probability of the mail to be spam or ham is equal, so Pr(S) = Pr(H) = 0.5.

a. Calculating individual probability

The overall probability of an email being spam, regarding all of the tokens or a set of tokens of the mail can be calculated using the following formula**:**

$$P = \frac{P_1 P_2 \ldots\ldots\ldots P_N}{P_1 P_2 \ldots\ldots\ldots P_N + (1-P_1)(1-P_2)\ldots(1-P_N)} \quad (3)$$

Here,

- P is the probability spam of a fishy message.
- P_1 is equal to the probability of $P_r(S|W_1)$.
- P_N is the probability $P_r(S|W_n)$

The output of the formula p is usually compared to a defined point for deciding a spam or ham message. If the probability is greater than the specified value, the message is considered spam. Otherwise, it is not a spam message.

b. Overall View of Naïve Bayes' Formula:

Naïve Bayes is easy, but effective classifier.it is totally based on the Bayes theorem. This feature defines feasibility related to a class based on the probability of each attribute value. Abstractly, NB is a conditional probability model: given a problem instance to be classified to any class {Cj }1<j<n, represented by a vector of features (independent variables) X € {x1…..xn} it can be formally shown as:

$$C_{MAP} = argmax_{c \epsilon C} P(x_1, \ldots\ldots\ldots, x_n | c) P(c) \quad (4)$$

$$C_{NB} = argmax_{c \epsilon C} P(c_j) \prod_{x \in X} P(x|c) \quad (5)$$

Reducing the number of parameters required for modeling the important advantages of the NB algorithm in technical concerns. Exemplary, due to the independence assumption, we need 2n parameters to model P (X|Y) instead of the original 2(2n – 1). These quality procedures guarantee simplicity and speed.

C. Support Vector Machine (SVM)

SVM is associated with statistical learning theory. In 1992(Boser, Guyon & Vapnik), it was first introduced properly [10]. SVM algorithm became popular after getting success in handwriting digit recognition.

Training data consists of input and output functionality is known as supervised learning in machine learning. The support vector machine (SVM) is one of the supervised machine learning algorithms [11]. It is mostly used for solving two-group classification problems. In this system, it is used for differentiating between spam and ham.

An SVM training algorithm builds a model that enrolls new examples to one of the two categories which makes the non-probabilistic binary linear classifier. If the new example which will be classified falls into one side of the hyperplane, it is defined in the category according to the class of that side.

Beside linear classification, different types of method are introduced like kernel trick, etc. for non-linear classification in SVM.

D. Natural Language Tool Kit (NLTK)

As the first challenge to create a spam filter was to build an SVM that will take input an email and extract the words as well as sentences of the message body. So that there will be word to word and sentence to sentence comparison simultaneously, to calculate spam probability. For this approach, the Natural Language Tool Kit (NLTK) is used in python programming.

The NLTK is introduced for helping the system with Natural Language Processing (NLP) technique. The NLKT helps the system by splitting sentences from paragraphs, splitting up words, recognizing the part of speech of those words and so on. However, the primary purpose of using NLTK is the tokenization of sentences and words.

IV. PROPOSED METHODOLOGY

A. Algorithm for Building the filtering system

The total process is given below sequentially.

1) Retrieving spam and ham email messages

A lot of sample ham and spam messages are needed to train the SVM. Almost 16,000 ham messages and 3,000 spam messages have been collected from the machine learning repository of Enron dataset [12]. The system retrieves all the messages one by one and takes it into the machine.

2) Tokenization

Tokenization is done into two steps. Each email is split into two parts, words and sentences are separately taken. Words are directly listed into a database which is called data dictionary. Using NLTK, the sentences are converted into a vector and then stored to the data dictionary.

3) Feature Extraction

Feature extraction measures the frequency of spam and ham emails. Generally, each of the words is labeled 0 if it came from the ham email and labeled 1 if it is from spam email. In this method, the vectors generated from sentences are also labeled 0 and 1 in accordance with spam and ham messages. In this way, SVM calculates the frequency of the tokens.

4) Shuffle the data dictionary

After labeling, all the tokens are stored in the data dictionary in the format of the 2D array in a random approach. The spam and ham email messages are stored randomly in the data dictionary.

5) Generate. sav file

After completion of all the steps above, SVM generates a .sav file which contains the training datasets of the data we have collected to train the system.

6) *SVM. Seeding database*

The data dictionary has been seeded with spam and ham messages as many as possible. The more data added, the more accuracy of a mail being ham or spam will be achieved.

7) *Test method (Input message)*

After training the SVM with enough datasets of spam and ham emails, the testing session has been taken place. A sample email body has been taken to test.

8) *Tokenization of test message*

The whole message is split into two portions. One portion takes the word and keeps them in an array and another portion converts every sentence into a feature vector and keeps it in an array.

9) *Frequency calculation*

After tokenizing the test message, the frequency of each token and vectors in the token list is calculated.

10) *Retrieve Spam and Ham frequency*

In this step, the spam and ham frequency is retrieved from the training datasets of our SVM model.

11) *Retrieve Spam and Ham count*

Spam and ham count are done from the datasets.

12) *Calculate Spam probability*

Calculate the spam probability of each token that is found in the database using the following formula:

Spam probability, P_s

$$P_S = \frac{\text{spam frequency in database}}{\text{number of spam mail in database}} \quad (6)$$

If the probability is greater than 1, set it to 1.

13) *Calculate Ham Probability:*

Calculate the spam probability of each token that is found in the database using the following formula:

Ham probability P_H,

$$P_H = \frac{Ham\ frequency\ in\ database}{number\ of\ Ham\ mail\ in\ database} \quad (7)$$

If the probability is greater than 1, set it to 1.

14) *Calculate Spamicity*

Calculate the spamicity of each token that is found in the database output of "(6)" & "(7)" using the following formula:

$$\text{Spamicity} = \frac{P_S}{P_S + P_H} \quad (8)$$

15) *Total spam probability:*

Calculate the total spam probability using the output of "(8)". It can be found as:

$$\text{Total probability} = (S_1 * S_2 * .... * S_n) + ((1-S_1) * \ldots * (1-S_n)) \quad (9)$$

Where,

- S_1 is the spamicity of 1st token.
- S_2 is the spamicity of 2nd token.
- S_n is the spamicity of nth token.

16) *Decision*

We examined the proposed system with different threshold values. Which shows the results in Table I.

TABLE I EXPERIMENTAL ACCURACY WITH DIFFERENT THRESHOLD VALUES

Value	.2	.3	.4	.5	.6	.7	.8
Accuracy(%)	39.11	60	80	90	85	70.21	43.55

When the threshold value is less than 0.5, the system considers some spam emails as ham. On the other hand, some ham email is considered as spam with the threshold value greater than 0.5. So, we considered 0.5 as an optimal threshold value.

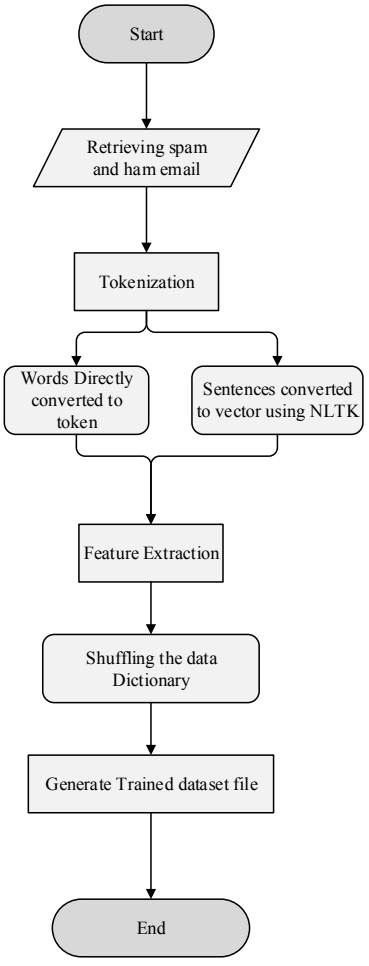

Fig.1 Representation for building Support Vector Machine (SVM)

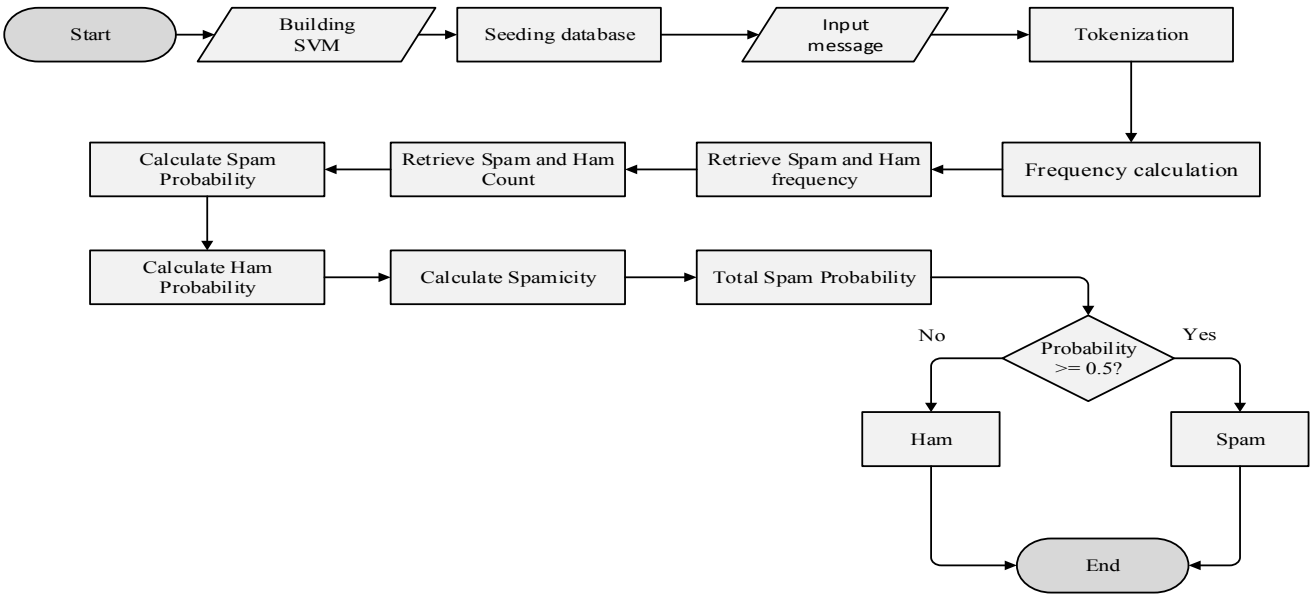

Fig. 2 Representation of Naïve Bayesian Spam Filter using SVM

B. Flowchart of the Naïve Bayesian spam filter using SVM

1) Building SVM

First of all, we have built an SVM for training datasets.

The flowchart of building SVM is in fig.1.

2) The complete procedure of Spam Filter

After successfully building the SVM, we prepared the spam filter for testing new mail. The whole process is shown in fig. 2.

V. Implementation of BayesiaN Filter

A. Sample spam message

The result of the algorithm after receiving a spam email and processing it with the system is shown using a well-known "Enron datasets" [12] spam message. The message is given below:

From: BUMA SARO WIWA <bsarowiwa@incamail.com>

B. Processing steps

1) Tokenization: After receiving the mail, the Bayesian spam filter first split the message into tokens. For the concern message tokens are shown in "table II". At the same time, sentences are separated too by counting the comma (,), full stop (.), exclamatory sign (!), interrogative sign (?), etc. punctuation marks. It is shown in "table III".

2) *Frequency Calculation*: Using the stop words list, we eliminate the unnecessary words that are not effective in spam detection. Then the frequency of single tokens is calculated. After that, with the help of NLTK, the sentences are converted into feature vectors, and then their frequency is also calculated.

TABLE II TOKEN LIST (WORDS)

Dobmeos	with	hgh	My	energy
level	has	Gone	up	stukm
human	growth	hormone	also	Called
hgh	Is	Referred	To	in
medical	Master	hormone	It	Is
very	plentiful	When	we	are
Young	but	near	The	Age
Of	Twenty	one	our	Bodies
Begin	to	Produce	less	of
It	by	the	Time	we
are	Forty	nearly	everyone	Is
deficient	of	In	hgh	and
At	eighty	our	Production	Has
normally	Diminished	at	least	90-95%
advantages	of	Hgh	Increased	muscle
Strength	loss	In	Body	fat
increased	Bone	density	lower	Blood
Pressure	quickens	Wound	healing	reduces
Cellulite	improved	vision	Wrinkle	disappearance
increased	Skin	thickness	texture	Increased
energy	levels			

3) Retrieve Spam and Ham Frequency: Retrieve Spam and Ham Frequency: From the SVM, the data dictionary has retrieved where the spam and ham frequency is stored.

TABLE III TOKEN LIST (SENTENCES)

Sentence
Dobmeos with hgh my energy level has gone up
Introducing doctor – formulated hgh
human growth hormone - also called hgh
It is referred to in medical science as the master hormone
it is very plentiful when we are young
but near the age of twenty - one our bodies begin to produce less of it
by the time we are forty nearly everyone is deficient in hgh
and at eighty our production has normally diminished at least 90 - 95 %. advantages of hgh
increased muscle strength
loss in body fat
increased bone density
lower blood pressure
quickens wound healing
reduces cellulite
improved vision
wrinkle disappearance
increased skin thickness texture
increased energy levels
improved sleep and emotional stability
improved memory and mental alertness
increased sexual potency
resistance to common illness
strengthened heart muscle
controlled cholesterol
controlled mood swings
improved memory and mental alertness

Subscribe today

4) Retrieve spam and ham count: After getting the spam and ham frequency, we now go through the spam and ham count. Here numbers of spam and ham messages from the data dictionary are found.

5) Calculate spam and ham probability: In this step, the spam and ham probability of each token, and vectors generated from sentences are calculated using the formula discussed above. If either spam or ham probability is found greater than 1, and then it is set to 1.

6) Spamicity Calculation: The spamicity of each token is calculated by using spam and ham probability using the formula discussed above.

7) Total spam probability: In our test mail, there are 122 tokens for words, and 27 vectors generated from sentences. It is really a lengthy calculation, so it would take some time in the compiler to show the result.

Using Naïve Bayes formula, the total probability of the message to be a spam can be calculated as:

Term 1: (0.99911) (0.654) (0.756) (0.889) (0.776) (0.445) (0.667) (0.334) (0.554) (0.233) (0.556)……. (0.912) (0.814) (0.823)

Term 2: (1-0.99911) (1-0.654) (1-0.756) (1-0.889) (1-0.776) (1-0.445) (1-0.667) (1-0.334) (10.554) (1-0.233) (1-0.556) ……. (1-0.912) (1-0.814) (1-0.823)

$$Total\ spam\ probability = \frac{Term\ 1}{Term\ 1 + term\ 2} = 0.74 \quad (10)$$

We can see that the final probability of the message to be spam is 74%. In our methodology, we have already stated that our probability measurement threshold value is 0.5. If the probability is greater or equal to 0.5, the message will be considered spam, and if less, we will consider it ham.

VI. ANALYSIS OF THE PROPOSED SPAM FILTER

A. Experimental Result

We have tested the performance of the spam filter using the corpus of the SpamAssassin project of Apache Foundation [13]. For some sample input email, the output of the Naïve Bayesian spam filter is given in "table IV" & "table V".

TABLE IV EXPERIMENTAL RESULT OF NÄIVE BAYESIAN FILTER

Steps	Total no. of Email (input)	No. of Spam (input)	No. of Ham (input)	No. of Spam (output)	No. of Ham (output)
initially	120	45	75	-	-
1	30	10	20	9	18
2	60	30	30	28	27
3	90	38	52	34	45
4	120	45	75	39	68

Experimental result of false positive, false negative and accuracy of "table IV" is shown in "table V".

TABLE V EXPERIMENTAL RESULT OF NÄIVE BAYESIAN FILTER

Steps	False Positive (Output)	False Negative (Output)	Accuracy (%)
initially	-	-	-
1	1	2	90
2	2	3	91.67
3	4	7	88
4	6	7	87

We considered a total of 120 emails among them 45 spam and 75 ham/nonspam. The input emails are provided in four steps. At step-1 and step-2, step-3 and step-4 total 30, 60, 90, 120 emails are used respectively.

During the experiment for step-1 and step-2, we used one spam and one ham alternatively. This is done so that there is a balance between the spam and ham database. For the next two steps, no such order was maintained.

B. Comparative Analysis

Naïve Bayesian spam filters are adequate to detect spam than other types of filters such as K-means clustering [6], deep learning [9]. But supervised learning is better than unsupervised learning in this case, and deep learning is a complex process to classify spam and ham. So, we can say that our filtering technique using a Naïve Bayesian spam filter is legitimate.

Another reason for the great performance of Naïve Bayesian spam filters is that most of them that are available and personally trained by individual users to better filter their emails using own set of the token. But other filters don't support this feature such as signature-based and list-

based filters are used in the server side and rule-based filters support client-side filtering but in small scale. Comparative analysis is shown in "table VI".

The learning system is slower than other approaches because it works with lots of tokens and database. It takes time to retrieve, insert and update the database each time. But other systems do a little business with the database than learning-based systems. Learning systems are reliable because it works with the content of the email rather than the sender or sending network of the message. As a result, the spammer cannot circumvent the filter by sending it from a new address or network. This increases the reliability of learning systems while rule-base and list-based are less reliable.

TABLE VI COMPARATIVE ANALYSIS OF FILTERING SYSTEM

Filter Type	Fast	Reliable	Dynamic	Application Area
Signature-based	Yes	Yes	No	Server
Rule-based	Yes	Sometimes	No	Both server and client
Our proposed filter	No	Yes	Yes	Both server and client
List based	Yes	Sometimes	No	Server

It is also worth mentioning that the Naïve Bayesian spam filter is not our new invention. We added some more techniques to enhance reliability, accuracy, and dynamicity. Fig. 3 depicts the comparison between the conventional Naïve Bayesian spam filter [14] and our proposed model. We calculate average accuracy, recall, precision, F1-measure.

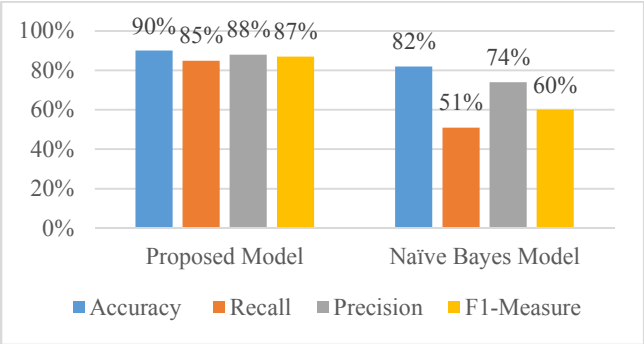

Fig.3 Comparison with the Naïve Bayes Model

The comparison clearly says that our proposed model is best suited in all the purposes.

VII. Conclusion

No spam filter can detect spam with 100% accuracy. So, the proposed spam filter is not above all weakness but we can certainly improve the performance of the filter by incorporating various features into the filter. The accuracy of the filter is shown based on some real-time data during the experiment phase of the filter, and we have gained the accuracy of spam detecting at a standard level of 88%. The accuracy can be increased by tokenizing the incoming email more efficiently and suitably building the spam and ham seeding database with proper tokens. The accuracy also depends on the order at which emails are received during the training period of the database. Lastly, to defeat spam, it is more important to analyze the content of the mail than other techniques, because the content is everything for the spammer to deliver to the people. Spammers are getting smarter day by day. But with proper analysis of content and a large amount of data training, it is possible to develop an efficient spam filter. Hence, there is a lot of scope for future improvement. Modern email system also contains HTML data, images, and other languages besides English and so on. None of these things are considered in the system. One can work with these fields for detecting spam email more effectively.

Abstract – **In mobile robotics measuring displacement with high level of certainty is very critical to successful localization and mapping. However, sensors such as the depth cameras and LIDARS are often very expensive and difficult to obtain in Bangladesh. To circumvent this problem researchers in Bangladesh uses HC-SR04, a low-cost ultrasonic ranger finder for displacement measurement. MPU6050 a low-cost IMU contains a 3 axis accelerometer which enables it to calculate displacement by double integrating acceleration data. This paper compares the displacement measured using HC-SR04 to the displacement measured by MPU6050 in order to determine whether the displacement calculated from the accelerometer data alone is sufficiently accurate for robot localization. Single step trapezoidal integration method was used and the accelerometer was calibrated using 7000 data sample requiring 1604ms. A convolution type Moving Average Filter took acceleration data 64 times in each time instance for removing noise signals. All data were updated in 15ms intervals. A novel multiplier called Scale Factor (S.F) was introduced to compensate for the resolution issue without amplifying noise signals. Experimental result showed that displacement calculated from accelerometer data can estimate displacement in a mobile robot with reasonable accuracy, provided some assumptions are taken which are not representative of the real world scenarios.**

Keywords — Linear displacement, MPU6050, HC-SR04, accelerometers, moving average, double integration.

I. INTRODUCTION

Localization, the process of determining a robot's position in the world coordinate frame has received much attention in the last decade. A key part of this process is finding the displacement of the robot with high accuracy. This is of paramount importance as literature on the topic indicates that accurate localization leads to accurate environment mapping and an accurate map facilitates in better localization [1 2]. Robots which have been successful in localization (and consequently mapping) are often outfitted with high-performance LIDARs, research grade Inertial Measurement Units (IMU), depth perception cameras and powerful onboard computers. A couple of examples in this regard are the University of Waterloo's 2013 NASA Sample Return Robot [1] and CMU's Atlas with the Multisense SL sensor [2]. However, hardware used in such projects are often very expensive. For example, the IMU used in [1] costs around $1500 while the price of the LIDAR used was around $2000. Funds for such high-cost equipment and technical support from sensor manufacturers are very difficult to obtain by roboticists here in Bangladesh due to various socio-economic reasons.

Thus in order to implement robot localization, engineering students and scientists in Bangladesh often rely on low-cost hobby grade sensors such as the HC-SR04 Ultrasonic ranger for object detection and distance measurements. They also use Invensense MPU6050, a low-cost IMU for measuring motion and orientation in 3D space. Use of HC-SR04 and similar low cost ultrasonic sensors have been studied extensively in works such as object detection, analysis and classification [3, 4, 5], binaural ultrasonic sensor pod design for obstacle avoidance, in a quadruped robot [6], design of one-class classifiers for human detection [7], signal analysis metrics for low cost ultrasonic sensors [8] and using an array of HC-SR04s to demonstrate the usage of Kalman Filter for accurate obstacle detection in an UAV application [26]. From these studies, it can be inferred that HC-SR04 is capable of measuring distances from inanimate objects made of materials such as wood, plastic, brick wall with the high degree of accuracy provided they are placed perpendicularly to its view cone and located at a distance between 20 cm to 150 cm.

Invensense's MPU6050, a well-known commercial IMU is composed of 3 axis gyroscope and 3 axis accelerometer with an auxiliary port for connecting external magnetometer for full 3 axis orientation measurement. Madgwick el at [9] showed the capability of this low-cost IMU for accurately measuring the 3D orientation of an object in comparison with a propriety Kalman filter and ground truth data from an external optical measurement. His work showed that MPU6050 can work very well with an 8bit microcontroller which possesses very limited computing resources for robust orientation measurement. Since then the MPU6050 have seen use in numerous scientific studies such as Fabio Varesano's open source hardware IMU framework [10], smart glove to translate hand gestures into sign language [11], direction agnostic fall monitoring device for old people [12], pose determination for balancing robots [13 14] and so on.

A key benefit of having an onboard accelerometer on a mobile robot is that it is possible to determine displacement (or distance) from the accelerometer data directly using double integration. This has been thoroughly examined in [15, 16, 23]. Furthermore, from those studies, it was shown that a system which accelerated and decelerated relatively at a constant rate, its displacement can be estimated using the Trapezoidal numerical integration method whose result remained within an acceptable margin of error. Motivated by these findings, we present our study of comparing the displacement measured by HC-SR04 with the displacement calculated from accelerometer data of MPU6050. Our goal is to answer whether the data from an accelerometer alone is sufficient to determine the displacement of the robot with reasonable accuracy.

For this study we take the following assumptions:

i. The robot moves only in the positive X-axis direction of the IMU.

ii. Taking one axis data of the accelerometer is sufficient to remove the effects of normal forces exerted due to earth's gravity on the accelerometer.

iii. The distance measured by the HC-SR04 ultrasonic sensor is accurate and precise.

iv. The time interval between each reading is identical.

The rest of the paper is arranged as follows: Section 2 describes the experiment procedure, Section 3 describes our findings and Section 4 concludes the paper discussing some of the shortcomings and potential future studies.

II. METHODOLOGY

Fig. 1 shows our test robot for this experiment. It is a food serving robot built to study the interactions between the robot and the students in a dynamic cafeteria environment. At the time of writing this paper, it is a two-wheel drive mobile robot consisting of an Arduino Due embedded development board based on Atmel SAM3X8E, an ARM Cortex-M3 32bit microcontroller running at 86 MHz. It is outfitted with an expansion shield to interface a 16 by 2 Liquid Crystal display (shown in Fig. 2) and a GY-86 10DOF sensor board comprising of InvenSense MPU6050 a 6 axis inertial measurement unit (IMU). The robot is powered by a 3 cell 12.6V 36.6Wh Lipo battery. The Atmel SAM3X8E is programmed using the open source Arduino software framework [21]. The data from MPU6050 is read using I2CDevlib library written by Jeff Rowberg [19] and the ultrasonic sensor data was read using the NewPing library by Tim Eckel [20]. All accelerometer data were captured using CoolTerm serial monitor written by Roger Meier [24].

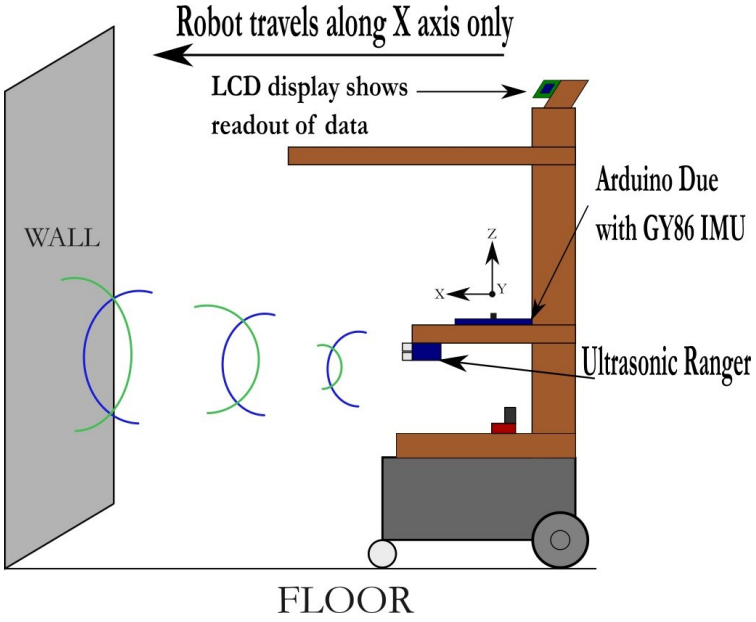

Fig. 1 Schematic diagram of the experiment process

From the datasheet of MPU6050 [22], the full-scale range of the accelerometer was set to ±2g and sensitivity scale factor was set to 16,384. This means that if the output from the accelerometer is 16,384 on a particular axis then the sensor is measuring 1g force on that axis. The accelerometer is then calibrated keeping the robot stationary and the zero reference values for all three axes were determined by averaging the values of 7000 samples. The HC-SR04 ultrasonic sensor was calibrated prior to its installation on the robot. We ascertained that our HC-SR04 unit can measure distances between 20cm to 150cm accurately with 1-1.5% of error when compared to physical measurements using a tape ruler. After calibration, the robot is placed 150mm away from the wall as shown in Fig. 1 for each run. The robot moves forward for 2s in each cycle while recording displacement measured by the ultrasonic sensor and accelerometer simultaneously. Deducting the distance measured by the ultrasonic sensor from the initial and final positions gives us the ground truth data for comparing the displacement calculated using the data obtained from the accelerometer.

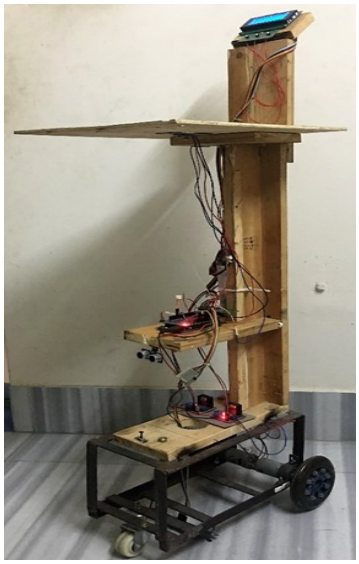

Fig. 2 Food serving robot showing all of its major components

Fig. 3 LCD showing calibration data

In each time increment, we log 64 readings from the MPU6050 and then fed the data through a Moving Average Filter, a Low Pass FIR filter programmed on basis of [17] and [18]. Our DSP filter is of convolution type, meaning each output point is produced by sampling a set of input points and then averaging the sum of those values. Mathematically this can be written as

$$y[i] = \frac{1}{M}\sum_{j=0}^{M-1} x[i+j] \tag{1}$$

The filtered value is then subtracted from the zero reference values for obtaining the body acceleration value at that instant. Even with two low pass filters implemented in software and hardware end (MPU6050 has a 250Hz low pass filter activated by default) respectively, noise signals were still present which registered erroneous displacements. To rectify this, we employed another software filter named Mechanical Noise Window (MNS) as discussed in [17]. Its low and high threshold values were determined experimentally. The acceleration values were then converted to cm/s^2 using the following equation

$$a_g = \frac{a_{LSB} * 9.81 * 100}{16834} cm/s^2 \tag{2}$$

This data is now suitable for double integration to determine the displacement of the robot in cm. We implemented the single step Trapezoidal rule for double integrating the accelerometer data using the following formulas adapted from [23].

$$\int_{t(0)}^{t(n)} a(t)\,dt \cong \sum_{i=1}^{n}\left(\frac{a(i-1)+a(i)}{2}\right)\Delta t \tag{3}$$

$$v_c(i) = S.F * v_c(i-1) + \left(\frac{a(i-1)+a(i)}{2}\right)\Delta t \tag{4}$$

$$d_c(i) = d_c(i-1) + \left(\frac{v(i-1)+v(i)}{2}\right)\Delta t \tag{5}$$

Here *dc (i)* is the instantaneous displacement and S.F is a "scale factor" which will be discussed in more details in Section III.

III. RESULTS AND DISCUSSION

To commence our study we required a suitable sample size for running the calibration routine. Table 1. shows the time required in milliseconds by the Atmel SAM3X8E for executing the calibration method for different sample sizes. It is clear from the data that once we move above 2000 sample size, the zero reference value for X-axis becomes stable. Since our experiment is designed to be implemented in short bursts, we opted to go for the 7000 sample size which requires 1604 ms to be executed.

TABLE I. EFFECT OF NUMBER OF SAMPLE POINTS ON CALIBRATION TIME

Number of samples	*Ax value (bits)*	*Time (ms)*
10	-124	2
50	-127	11
100	-99	22
150	-106	34
300	-120	68
500	-120	114
750	-114	172
1000	-117	229
1000	-119	231
2000	-123	458
3500	-123	803
5000	-122	1148
7000	-123	1604
7500	-122	1722
10,000	-122	2296

Table 2. shows the time required in milliseconds by the microcontroller to execute the moving average method in different configurations for removing noise signals from the accelerometer data. Iteration number here refers to the number of calibrated data the MCU will poll from the MPU6050 within the 15ms window to calculate the body acceleration value in LSB/g format [22]. The data showed that doubling iteration number doubles the time required to execute the Low Pass filter. However, for 256 and 512 iterations, the time required was exactly the same and this oddity held true after multiple calibration attempts.

TABLE II. Effect of the number of iterations on the loop time for executing moving average method

Iteration number	*Loop time (ms)*
8	2
16	4
32	8
64	15
128	30
256	59
512	59
1024	118

For our study, we chose 64 iteration number which is the sample size used in Freescale application note [17]. However, even with the Moving Average filter, there existed errors in accelerometer data caused by sensor noise. These errors were interpreted as a constant velocity by the microcontroller and consequently summed as a steady movement even though the robot was stationary. A second software filter dubbed the Mechanical Noise Window (MNS)

first introduced in [17] was used to cut off values within a certain band to eliminate this problem. Fig. 2 shows the raw and calibrated data from the accelerometer and Fig. 3 demonstrates the use of MNS to eliminate the erroneous displacement caused by the sensor noise shown in Fig 2. The error is linear in nature which was expected as in a standstill position, no other force was acting along the X-axis direction and on the basis of assumption 2, gravity vector which is assumed to be registered only along the Z-axis by the IMU in a stationary position was omitted from the start. On the basis of assumption 1, we only considered the absolute value of the calibrated data. As mentioned previously the motors are allowed to spin forward for only 2s. When the power is cut off the robot will decelerate but still move forward by some amount. Thus we are required to take the calibrated value because when decelerating, a negative displacement is computed which reduces the overall calculated displacement thereby giving false readings.

Table 3. shows the calculated displacement from the accelerometer data using (3 – 5). As shown in Fig. 1 the sonar, measures the robot's displacement from the wall by deducting initial and final position readings. The initial position for all runs is 150 cm. However, we noticed that the IMU data lagged behind irrespective of the number of iteration set for the moving average method. Using the CoolTerm serial monitor, we monitored the internal variables and deduced that with the default accelerometer sensitivity the IMU was not updating fast enough as its I2C bus is capped at 400Khz even though our microcontroller is capable of much faster data transfer.

34	35	115	93	70	19
35	38	112	105	70	6
36	37	113	107	70	5
37	38	112	113	75	1
38	38	112	114	75	2
39	39	111	113	75	2
40	37	113	110	75	3

We decided not to change the sensitivity factor as most of the literature on MPU6050 used the default sensitivity scale (+/- 2g). This is due to the fact that when the sensitivity of the accelerometer is increased, it proportionally increases the effect of the noise source in the measured signal. Sources of

noise in MEMS accelerometer is explained in depth in [25]. For the reasons above, we introduced a new multiplication factor named Scale Factor (S.F). S.F is an integer used in (4) to increase the value of velocity to compensate for the sensitivity problem without amplifying signal noise.

From Table 3, we observed that for a S.F value of 70, the data between the Ultrasonic sensor and accelerometer starts to converge well. Table 4. shows the data for determining a S.F value for which the error will be minimum.

TABLE IV. Determination of S.F value

No.	*Sonar final (cm)*	*Sonar displacement (cm)*	*Displacement IMU (cm)*	*Scale Factor (S.F)*	*Error (%)*
1	30	120	128	70	7
2	25	125	104	70	17
3	24	126	113	70	10
4	22	128	117	71.5	9
5	22	128	115	71.5	10
6	21	129	112	71.5	13
7	23	127	125	72.5	2
8	24	126	131	72.5	4
9	25	125	127	75	2
10	**26**	**124**	**124**	**75**	**0**
11	**25**	**125**	**125**	**75**	**0**
12	**23**	**127**	**131**	**75**	**3**

From Table 4 it is evident that the S.F value for our experimental robot is 75, a value for which the error is consistently within 5% of error margin. Our experiment indicates that low-cost IMU can be used for measuring linear displacement with reasonable accuracy but requires a controlled environment. Thus we conclude that though IMUs are capable of displacement measurements, they should not be used as the only sensing device for this purpose and should be coupled with other sensors such as HCSR04, LIDARs and so on. We claim this notion from the fact that at the onset of this study we had taken four assumptions. These assumptions are not representative of most real-world applications. A byproduct of our study is that both HC-SR04 and MPU6050 have shown remarkable performance with the Arduino platform which indicates their potential for use in complex projects by roboticists here in Bangladesh.

IV. Conclusion

This paper presents a comparative study of the performance and reliability of using low-cost commercial MEMS accelerometer in measuring linear displacement. It was compared to the displacement measured by HC-SR04, a low-cost hobby grade ultrasonic ranger widely available in Bangladesh. Even though a good agreement between the measured values were seen, assumptions were imposed which are not representative of real-world scenarios. Most notability assumption about the accuracy of HC-SR04 is not always fixed due to the fact that HC-SR04's view-cone changes with respect to the sensor's distance from the object. Furthermore, the assumption about each loop running at exactly 15ms is not true. In our initial trials, we had observed that as the ultrasonic ranger came closer to the wall, it changed the overall loop time. Tim Eckel's library resolved this issue by utilizing an independent *timeout* argument which allowed receiving data for a fixed period of microseconds before returning 0. We suggest that linear displacement computed from accelerometer data should be used in conjunction with other sensors. In this regard, the use of the weighted average method is recommended for maximum accuracy as in perspective of a microcontroller application, this method is easy to code and requires low computing resources. Our future work will include the use of all three axes data, advanced numerical methods and will use the timer modules to independently count time increments rather than depending on Arduino's delay method which drifts with time.

V. Acknowledgment

The authors acknowledge the support of the Department of Mechanical and Production Engineering of Ahsanullah University of Science and Technology for providing workspace in their Simulation Lab. We are also thankful to the open source Arduino community for providing the necessary codes and helpful documentation on interfacing HC-SR04 and MPU6050 with Arduino Due.

Abstract— **In the arena of Software Development, the software engineering philosophy Agile is becoming more popular juxtaposed to the long-established methods. Software organizations have a prerequisite from graduates with cutting-edge knowledge of software engineering methodologies. Due to Agile's popularity universities and institutions have already added agile in the curriculum of software engineering. They have started to teach the students Agile theoretically, practically in labs and also have some seminars where empirical knowledge is shared with students. This paper aims to acquit the determination of Agile to the perceptual experience of Software Engineering undergraduate students, after completing their projects in the lab by following Agile principles, where they were trying to adopt Agile.**

Keywords— Software Engineering Education, Agile Software Development, Software Project Management.

I. INTRODUCTION (*HEADING 1*)

As Agile frameworks are getting to be standard in the Software organizations [1] there has been an expansion in the interest for them be schooled in the classroom. Following Scrum, one of the most popular Agile frameworks has heightened in the last few years through the demonstrations of surveys. Considering "2015 state of Scrum Report" Scrum has been followed in organization for more than 50% of the time, and that 42% of responders follow Scrum entirely [2]. Regarding the VersionOne [3] State of Agile Survey, around 88% of responders are applying agile in the workspace. Apparently, it is hard to adopt the Agile principles as well as gain knowledge for most of the organizations. Agile is a philosophy to develop software with project management procedures, such as Scrum, eXtreme Programming (XP), Lean Software Development (LSD), Kanban, Adaptive Software Development (ASD), Feature Driven Development (FDD), Dynamic System Development Method (DSDM), Agile Modeling (AM), Crystal, Agile Unified Process (AUP) [4].

Agile Squads perform their jobs differently compared to other software development teams, where customers and team members have good continuous communication between them. They are delivering working software frequently. These types of duties need some essential accomplishments like communication skills and faster implementation potentiality. Advance, because agile squads are self-organized teams there is a demand to consume self-denial, a power to assume the obligation, to consecrate, plus take responsibility and tenure. So, this is an ecumenical swerve that pupils need to evolve not only fantabulous technological expertise but also capability of solving a problem, innovative skills of solutions, scheme skills, kinship attainments, to make a quick decision with ability in a fast surrounding [5, 6, 7].

A gap has been created between the knowledge and accomplishments instructed in universities and the one's prerequisite in software organizations, after the popularity of Agile use [8]. So that universities are now adding agile in their software engineering course curriculum, for a good outcome.

This paper intends to survey the relationship of tutoring Agile frameworks and the perceptual experience also may have called as an evaluation of undergraduate students of software engineering which are related to the Success Factors in Agile Software Projects (from Tsun Chow – 2007). We have to keep in mind that, this evaluation was done by those students who didn't know anything about Agile before studying the software engineering course. This work reports the leads of a first effectuation of agile learning in the circumstance of undergraduate Computer Science and Engineering (CSE) Education Department.

The theory of this research is finding students' team's performance to submit their software engineering project between a deadline fixed by their tutors. This paper can be a suggestion for other software project management education area.

The rest of the paper is written into following sections: Related Works in Section II, Description of class and lab environment in Section III, Research Methodology and Results Discussion are respectively in Section IV and V, Limitations, and Future Works in Section VI, and Conclusion in Section VII.

II. RELATED WORK

Although the agile framework has been nearby for more than a tenner, tutoring agile philosophy has just attracted substantial tending in research and educational fields in the endure years [10]. Many research workers have been admitted the demand to instruct the agile process in software engineering curricula [11, 12] as an intends to construct ethical and social skills in accession to technological [12]. There is arising consciousness that conventional theoretical speeches only unable to give students learn agile frameworks, instead students necessitate to essentially implement them for upskilling themselves and enriching the acquiring procedure [9, 13].

Be that as it may, revealing students to agile process and patterns in the context of university attaches to a set of disputes [10] counting, student aims, and motivation can be diverged [9, 14, 15], bounded availableness and backup from Product Owner/Client [14, 15], lack of counseling from experienced scrum master (Scrum) or a coach (XP) [15, 16, 18]. Another dispute reported let concisely length of classes with one-half of the course nonce consecrated to teaching constructs cutting time to projects work, students involved to

register multiple subjects in accession to their professional and personal dedications [14, 16]. As a result, now and then students seemingly benefit experience in exercising the agile frameworks, but they cannot be proficient to apply them acceptably [15, 16, 18].

More or less of the universities comprise agile patterns into the course through a dissimilar scaled (large, medium and small) sequence of projects [19] while others have taken the method of presenting agile philosophy in one semester followed by a final project in the following [17]. More or less allowed students to study agile approaches by functioning on software developments under the supervising of lecturers [21]. Not very many worked together with industry to increase the reasonable experience of teaming up with genuine clients through ventures [18]. Understudies taking a shot at existing industry frameworks is uncommon [20].

The curriculum of IS 2010 model indications "agile methods" in the subjects list for the IS 2010.6 Systems Analysis and Design class. Project management and Programming are two other subjects that may include agile approaches [22]. Schwalbe has combined agile into the textbook of project management [23, 24], though, the Project Management Institute (PMI) has approved agile notions in its outline, with proposing the Agile Certified Practitioner (PMI-ACP®) certificate [25].

Mahnic and Viljan Mahnic planned a software engineering course which is project-oriented, concentrated completely on Scrum by executing four sprints (three practical and one theoretical) in a semi--actual project. This type, of course, had prerequisite software engineering subjects where all the compulsory technical notions for basic software development were addressed consuming an 'old' software paradigm [26].

The selection of Agile philosophies has been demonstrated to encourage the administration of the development procedure, to lessen the additional time, and to decidedly effect on clients' satisfaction [26].

Structure upon this arising form of understanding, our paper exhibits the evaluation by students when applying agile on quasi-real projects, functioning in teamwork within university contexts and specific clients' requirements and description; and the adaptions made by student teams to agile patterns to work across the limitations. Moreover, perceived effectivity of these adaptions is talked about conducting to an understanding of the affect they made on students' learning based on success factors.

III. Our Class and Lab Environment

Software Engineering at our Computer Science and Engineering under the Faculty of Science and Engineering is a three semesters succession for specializations centering System Analysis & Design plus Software Engineering conceptions where the curriculum follows the textbook of Roger S. Pressman and Ian Somerville and the third one is Software Quality Assurance. Semesters have a closed theoretical class and sessional which copes with respectively 160 and 160 minutes hebdomadally. The requirement for the students are to attend classes and in labs with their required works. Tutors help students with troubles which are related to their assigned projects during lab as needed and discussed on theoretical software engineering in classes with historical data analysis and proper examples for each section of software engineering. Sizes of the course section are comparatively little, usually amongst 25 or 40 pupils.

Students were permitted to custom their very own teams of somewhere in the range of 3 and 4 each. The team measure considered randomness, more blend, and disallowed groups from complimenting excessively little because of drops or unlucky deficiencies. Companions would, in general, remain unitedly as did nonages. Certain students or the experts likewise would in general structure teams as did the less capable to complete a project. We experienced issues with this condition, such as teams with uneven aptitude levels. So after that, we have reformed some team members with adjusted abilities, and rouse every one of the students that all great in one part can't be a decent group.

From that point onward, each team has been appointed with software projects. The programming language for building up their software was freely picked by them. Each group was autonomous and had distinctive activities, yet being in a similar room, thoughts and ideas shared on a regular basis between teams. In the Fall 2018, the tasks were the genuine and real problem that the teacher of the class was keen on utilizing as a client. For practicing Agile principles, after each feedback teachers were changing the requirements.

Despite the fact that students at this dimension were not prepared to give real-time market software for genuine clients yet, we trusted they would profit by delivering something they knew was advantageous for a real "client," regardless of whether it was their educator.

This methodology additionally situated students for an imperative industriousness concern, the software developing that fulfilled clients as opposed to software that basically satisfied composed specification and features. The length of the task enabled the students to encounter three sprints and gave an adequate time span to take into consideration full of feeling development in group abilities.

Below are the assigned projects of Fall 2018:

- Bangladesh Travel Guide with interactive MAP feature – php Laravel 5.7
- Cha Wala (an android app for the Tea Stallers) - Java
- Boi-Mela (an online book selling market place) – php Laravel 5.7
- Nimontron (an event management system) – php Laravel 5.7
- Attendance System with Image Processing – Python
- Library Management System – Java
- Mini Militia (a game) – C# with Unity Game Engine

IV. Research Methodolgy

There were 24 students divided into 7 software projects following Agile for software engineering lab project. An online survey was created and sent to all students after completing their projects. The students' aspects and experience of abiding by Agile were accumulated through the contrived questionnaire based on Success Factors in Agile Software Projects. The inquiries were acquired and chose from the success factors [27].

The Organization factor dimension was excepted since the students are not expert in the real workspace. Consequently, in the questionnaire, there were questions in 4 dimensions namely People, Technical, Process, and Project and the questionnaire can be found here:

https://forms.gle/BAWKXquD7KB2V6ib9

Several success factors in a particular dimension are not incorporated due to their young programmers standing too narrow and cumbersome for the respondents. In order to assess the observations of respondents practicing Agile frameworks, closely answered inquiries with a Likert scale of 1 (strongly disagree) to 5 (strongly agree) were included.

Reason for choosing Agile: There are so many methodologies to develop software, and in a limited time of classroom projects are so small rather than developing in an organization. So, waterfall the traditional methodology of developing software can be used here but it's not followed by the students for their learning. Organizations are now following Agile frameworks to satisfy their customers with their requirements which are changing frequently after a sprint during the feedback session. Agile is followed here mainly to prepare the mind of students with its rules. Respective faculties have changed the requirement frequently as like customers. Students were bound to keep an update through using OrangeScrum, the open source project management, and collaboration tool helps to manage projects, team, tasks at one place. Students were given an update in their team's account frequently.

V. Results and Discussions

The statistical procedure was used to break down the data of 24 respondents, as well as qualitative data analysis for the replies through the open questions in the questionnaire. Considering the result of success factors, the majority of the students accounted for positive responses about following Agile in their semester project as demonstrated in TABLE I.

TABLE I. Survey Responses

Dimensions	Sl.	QUESTIONS	Series 1					Total
			Strongly Agree (%)	Agree (%)	Neutral (%)	Disagree (%)	Strongly Disagree (%)	
People	Q1	AGILE is a useful framework to develop a good kinship between practitioners and clients	66.67	25.00	0.00	8.33	0.00	24
	Q2	AGILE is a philosophy to motivate practitioners	25.00	70.83	0.00	4.17	0.00	24
	Q3	AGILE philosophies assist Knowledge Direction	29.17	41.67	25.00	4.17	0.00	24
Technical	Q1	AGILE uses a programming criterion to accomplish ends	29.17	58.33	12.50	0.00	0.00	24
	Q2	AGILE is capable to deliver working software frequently	45.83	41.67	4.17	8.33	0.00	24
	Q3	Students are willing to prioritize task befittingly after following AGILE	12.50	66.67	20.83	0.00	0.00	24
	Q4	AGILE helps the pupil to produce a suitable testing	29.17	58.33	0.00	12.50	0.00	24
	Q5	AGILE can ascertain a flaw in a team which assists the practitioners to explore a suitable resource like an experienced and skilled person	45.83	41.67	4.17	4.17	4.17	24
Process	Q1	AGILE assists the practitioners to infer the prerequisites perfectly	41.67	58.33	0.00	0.00	0.00	24
	Q2	Practitioners can use AGILE frameworks to track and monitor their works until the deadline	37.50	45.83	16.67	0.00	0.00	24
	Q3	Students are able to evaluate and predict the progress of the project submit within the deadline	29.17	50.00	20.83	0.00	0.00	24
	Q4	Students achieve more skills in communication by planning the project development and solve each problem when the requirements change frequently by Course Teacher	45.83	50.00	4.17	0.00	0.00	24
Project	Q1	AGILE philosophy is suited in little teams	25.00	50.00	16.67	8.33	0.00	24
	Q2	AGILE philosophy is suited in a project which is dynamic compared to a project which is static	41.67	45.83	8.33	4.17	0.00	24
	Q3	AGILE philosophy is appropriate for the projects with no several autonomous squads	8.33	50.00	20.83	20.83	0.00	24

At undifferentiated rate from the over factor, the following assuming purpose of Agile is characterizing the shortcoming viewpoint of a team. Usually to demonstrate that the speed of each sprint discharge undertaking relies upon individuals or the team. Without an exact leader, Agile team is performing [28], Scrum master defined as a part of a team to supervise, actuate and tracking another member when the team confronts a difficulty [29]. Any of these individuals in a group can be a Scrum Master to share an alternate quality and shortcoming perspective in a group. The scrum master can break down team issues and gather the frail focuses toward the finish of each sprint discharge or amid the daily scrum

meeting. The shortcoming focuses can be explained by sending the group to a fitting instructional class. In any case, there are some minority viewpoints about Technical components. As per the aftereffect of an assessment, it was demonstrated that the coding style is not really utilized by the members as unpracticed designers. The ability of coding relies upon the involvement of programming advancement. While the team was utilizing Agile for a software project, it is hard to keep the standard of each bit of assignments with individuals ailing in developing the experience of the software. This shortcoming side can influence task delays.

We have prepared graphs based on the percentages of the answers of students where each one denoted as Q1, Q2 series with the name of the dimensions and the graphical measurements were denoted as Series 1 which is mentioned on the table too. These graphs were prepared for the help of the readers and future researchers.

VI. Limitations and Future Works

The authors think that the limitations of this paper and works are

- The limited size of responders,
- Bounded numbers of Success Factors in Agile Software Projects
- Not following a remarkable Agile Framework in software engineering Lab to coach students to be a companion with at least one of the Agile frameworks rather follow the Agile philosophy, that has been accepted for software developing project management in the software organizations.

The more works and researches are required to deal more questions, features and students' observations and evaluations of teaching the Agile framework at the students of undergraduate level in diverse sections and concepts.

There are also have some success factors and practices of the practitioners who are following and maintaining Agile frameworks named Scrum, Kanban, XP [30] which should be discussed in the classrooms and should be followed by the

students' in the lab through completing a project, basically it can be possible in the Final Year project under an active supervision of faculties. After the successful completion of those projects, we will evaluate these again with the same students those who were responded in this survey.

VII. CONCLUSIONS

The master influence of this learning is to review the effect of the success factors of projects using Agile to the insights and knowledge of the students. The intended questionnaire was sent out through google doc for collecting data from 24 undergraduate computer science and engineering pupils. The initial consequences showed that most related dimensions of success factors of Agile espousal were People, Technical, Process and Project respectively. The supreme selected success factors for each dimension is the convincing connection between the practitioners and end-users, prioritizing projects and enforcing the jobs first, supplying thoroughly and essential coaching, participating client engagement, and a few amounts of practitioners in a team for each project. But then, the to the lowest degree success factors to each one is cognition direction, unequivocal writing in code standard, in the nick of time for case-by-case work deliverance, active and accelerate the schedule of task sets. This investigation shows that the People dimension of following Agile frameworks was most bucked up in the education of software engineering at undergrad phase.

***Abstract*—Network intrusion classification in the imbalanced big data environment becomes a significant and important issue in information and communications technology (ICT) in this digital era. Presently, intrusion detection systems (IDSs) are commonly using tool to detect and prevent internal and external network attacks/ intrusions. IDSs are majorly bifurcated into host-based and network-based systems, and use pattern-matching techniques to detect intrusions that known as misuse-based intrusion detection system. Machine learning (ML) and data mining (DM) algorithms are widely using for classifying intrusions in IDS over the last few decades. One of the major challenges for building IDS employing machine learning and data mining algorithms is to improve the intrusion classification accuracy and also reducing the false-positive rate. In this paper, we have introduced a new method for improving detection rate to classify minority-class network attacks/ intrusions using cluster-based under-sampling with Random Forest classifier. The proposed method is a multi-layer classification approach, which can process the highly imbalanced big data to correctly identify the minority/ rare class-intrusions. Initially, the proposed method classify a data point/ incoming data is attack/ intrusion or not (like normal behaviour), if it's an attack then the proposed method try to classify attack type and later sub-attack type. We have used cluster-based under-sampling technique to deal with class-imbalanced problem and popular ensemble classifier Random Forest for addressing overfitting problem. We have used KDD99 intrusion detection benchmark dataset for experimental analysis and tested the performance of proposed method with existing machine learning algorithms like: Artificial Neural Network (ANN), naïve Bayes (NB) classifier, Random Forest, and Bagging techniques.**

***Keywords*—Data Sampling; Ensemble Learning; Intrusion Classification; Imbalanced Big Data; Random Forest;**

I. Introduction

In recent times with the encroachment of information and communication technologies, computer networks are facing threats like worms, viruses, adware, spyware, rootkits, trojan horses etc. [1]. These sorts of threats/ intrusions have turn into a major apprehension and need to be perceived before destructing the computer networks. These intrusions are affecting the productivity of computer networks, organizational electronic assets and other resources. Intrusion detection system is a network security technology to identify malicious activities/ intrusions from host or network by inspecting networks and systems [2]. Network-based IDS (NIDS) and host-based IDS (HIDS) are frequently used to identify internal or external malicious activities/ intrusions. NIDS scrutinizes and monitors incoming network traffic to detect network intrusions [3]. HIDS is devoted to a singular host or computer device to detect intrusions by scrutinizing inbound and outbound packets [4]. In detection approach, IDSs are categorized as misuse-based or anomaly-based IDS [5]. Misuse-based IDS is also acknowledged as pattern-based or signature-based IDS [6]. It is incapable of detect anonymous intrusions and detection rate is comparatively low because attackers endlessly try to attack with dissimilar signatures [7]. Otherwise, anomaly-based IDS is extensively used to detect known or unknown network intrusions [3]. Network intrusions are identified by ascertaining hidden intrusion patterns from large volume of network intrusion detection dataset [8]. Many machine learning (ML) and data mining (DM) algorithms such as ANN, SVM, decision tree (DT), genetic algorithm, naïve Bayesian, fuzzy logic etc. [9] have been employed to classify intrusions in IDS over the last few decades. Today's obtainable network intrusion detection datasets are pointedly imbalanced, multi-faceted, dynamic and composed of different inconsistent data that causes problem to handle entire data. Many machine learning algorithms have been miscarried to identify all sorts of attack with high detection accuracy because some of the attacks occurrence in the dataset are too low compared to other attacks. Today's accessible intrusion detection systems have low detection accuracy and high false positive rate for all sorts of known or unknown network attacks/ intrusions [10].

In this paper, we have introduced a new method for improving detection rate to classify minority-class network attacks/ intrusions using cluster-based under-sampling with Random Forest classifier. Initially, the proposed method classify a data point/ incoming data is attack/ intrusion or not (like normal behaviour), if it's an attack than the proposed method try to classify attack type and later sub-attack type. We have used cluster-based under-sampling technique to deal with class-imbalanced problem and popular ensemble classifier Random Forest for addressing overfitting problem. The foremost purpose of this paper is to enhance the detection accuracy of low-frequency attacks in imbalanced network intrusion classification. We have built several classification models employing ANN [9], NB classifier [11], Random Forest [12], Bagging [13] and compare the performance of these existing learning methods with proposed method. The proposed method achieved 98% detection rate on average on the KDD99 benchmark dataset in compare with existing classifiers.

The rest of the paper is organized as follows. Section II presents the related works. Section III presents an effective multi-layer hybrid method. Section IV provides experimental results based on KDD99 benchmark dataset. Finally, Section V presents conclusions and future works.

II. Related Work

Singh et al. [1] presented an Online Sequential Extreme Learning technique to reduce the slow learning drawback of neural network for intrusion detection. They reduce the volume of the training instances and time complexity by applying beta and alpha profiling respectively. They also discarded irrelevant features by using consistent feature selection techniques and ensemble of filtered. KDD 2009 dataset is used to measure the performance of proposed technique. The proposed IDS achieved an accuracy of 98.66% and 97.67% with false positive rate of 1.74% for binary class and multi class respectively. The proposed IDS outperformed other published techniques based on the accuracy and detection time. Farid et al. [14] introduced a new learning method using NB classifier and an ensemble approach for adaptive intrusion detection. The proposed method can classify a known or unknown instance by considering the votes of a series of classifiers. This method can update the weights of training instances based on the outcome of classification error rates, which reduces the false positive (FP) rates and improves the detection rates (DR). They applied existing data mining algorithms and the proposed method by employing on the KDD99 dataset. The proposed method can abate the false positive rates and achieves high detection rates on different sorts of network intrusions. Farid et al. [15] introduced a new learning algorithm for anomaly-based IDS to detect known or unknown intrusions employing decision tree. It splits and adjusts the weights of each instance based on probabilities until all the sub-dataset belongs to the same class. The weights of every instance is same in conventional decision tree algorithms but in this method weights of every instance changes based on posterior probability. The proposed learning procedure achieved 98% detection rate on KDD99 dataset in comparison with other existing algorithms.

Li et al. [9] proposed a two-step hybrid intrusion detection method construct on k-NN technique and binary classification employing NSL-KDD dataset. Firstly, the proposed method uses the C4.5 algorithm to train binary classifier to identify uncertain classes. Secondly, the proposed method uses the k-NN algorithm to classify uncertain classes. By the amalgamation of these steps, the proposed technique outperforms baselines algorithms like Random Forest, naïve Bayes, backward propagation neural network and k-NN. The F1-scores of this proposed technique is greatly greater than these of baselines algorithms for U2R and R2L low-frequency attacks. Zarpelão et al. [16] presented an analysis on intrusion detection system research for IOT. They were experimented that the IoT research for IDS is still impending and their purposes are to recognize open issues, leading trends and the upcoming research possibilities. They were categorized the IDSs based on the IDS placement stratagem, validation strategy, detection scheme and security intimidation. They were discussed signature-based, specification-based, anomaly-based and hybrid detection mechanisms to develop IDSs for IoT. They also discussed about centralized IDS placement, distributed IDS placement and hybrid IDS placement techniques.

III. Learning Algorithms

A. Learning Scheme

We have used Random Forest as learning scheme in our proposed method. Random Forest is an ensemble learning method and used for classification and regression in supervised learning[17]. It has the capability of classifying big data with higher accuracy [18]. It constructs multiple decision trees depending on arbitrarily chosen group of attribute at training time and outputting the class that is picked from the votes of ensemble of trees as furthermost popular class [11]. There is a relationship between the accuracy and the number of trees, higher number of trees supposed to produce higher accuracy rate. One of the big problems of machine learning is overfitting, it occurs when model overfits to the training data that when new test instance comes to the model from outside of training data, it can not classify it correctly, it gives higher performance only if the training data is used as test data. Random Forest algorithm has solved this problem as it takes vote from the ensemble of trees, so it will not overfit the model. As it considers votes of every decision tree it has constructed, it is supposed to achieve much higher accuracy than a single decision tree [11].

B. Proposed Method

In the first layer of our proposed method, we built a model *M* using dataset *D* and Random Forest technique. When a new instance x_{new} comes in, model *M* predicts that weather it is an attack or not. Following that if x_{new} has been identified as normal we will leave it here but if it is predicted as an attack, we have divided the dataset *D* into two different datasets D_{attack} and D_{normal} respectively. We have worked only with the dataset D_{attack} and it includes 4 different category of attacks, $D_{attack} = D_{DOS} \cup D_{U2R} \cup D_{R2L} \cup D_{Probe}$. Among the 22 attacks in the KDD99 dataset, there is a huge imbalance data in the context of quantity. We had to do resampling to make it balance. In order to do that, in the second layer we have applied under sampling and over sampling techniques to the dataset D_{attack}. Cluster centroid technique was applied to do the under sampling, it partitions the instances *X* with a number of clusters $C_1, C_2, ..., Cn$ and takes only cluster centroids $Centroid(C_i)$ so that informative instances are not lost. After the proceeding, we have replaced the labels of the dataset D_{attack} with category of attacks. Then we have built another model M_{attack} using dataset D_{attack} and Random Forest. The category of attacks of x_{new} dataset has been predicted by M_{attack}. Now the domain of attacks has been shorted, so we have separated the data D_{new} from D_{attack} in the third layer. D_{new} contains instances *X* with only attacks of the predicted category of X_{new}. We have built our final model M_{new} with dataset D_{new} and Random Forest. It will predict the actual class or attack of x_{new}. The architecture of the proposed hybrid method is illustrated in Fig. 1 and algorithm is summarised in Algorithm 1. In Fig. 1, (a) the proposed method classify an incoming data is attack/ intrusion or not (like normal behaviour), if it's an attack then the proposed method try to classify main attack types shown in Fig. 1 (b) and later classify the final attack/ intrusion shown in Fig. 1 (c).

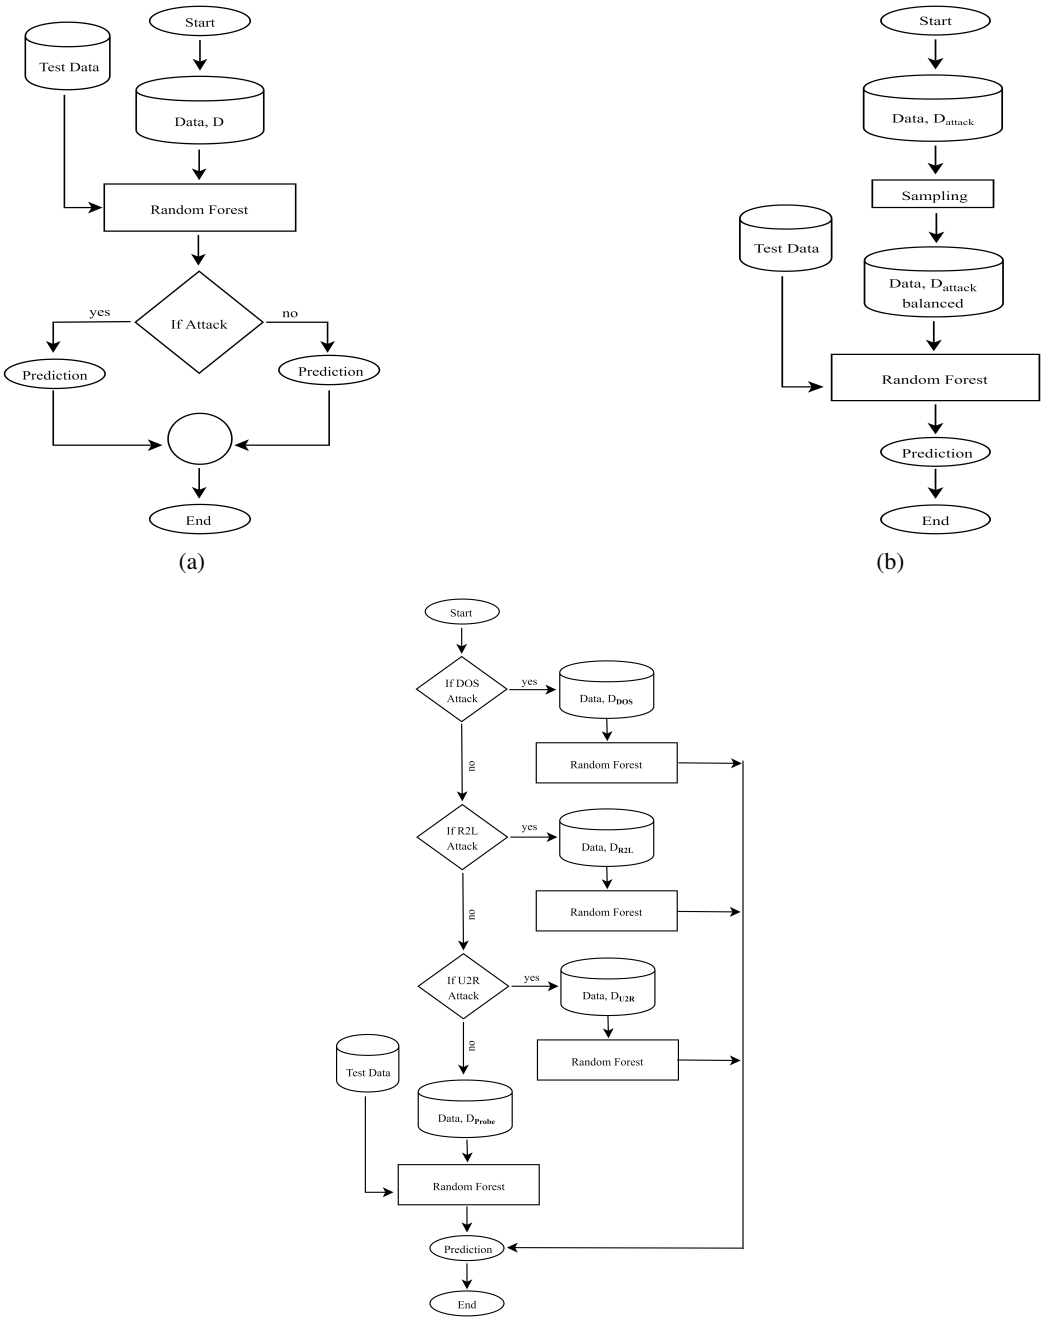

Fig. 1: Proposed method (a) normal or attack detection; (b) main attack types detection; (c) final attack/ intrusion detection.

IV. Experimental Analysis

The performance of classification algorithm is measured with several evaluation metrics in the literature. In this paper, we have used detection rates (DR) [17], false positives (FP) [17] as the standard evaluation metrics. Detection rate and false positive are widely used to estimate the performance of IDS that are shown in Eqs. 1 and 2.

$$DR = \frac{Total_dected_attacks}{Total_attacks} \times 100 \qquad (1)$$

$$FP = \frac{Total_misclassifed_process}{Total_normal_process} \times 100 \qquad (2)$$

A. Intrusion Detection Dataset

The intrusion detection dataset availability is very limited because it contains information about host, topology and other classified information. The KDD99 standard intrusion detection dataset was used to constitute network intrusion detector to differentiate between normal connections and intrusions in

Algorithm 1 Proposed Hybrid Method

Input: Data D, and a learning scheme.
Output: Prediction, C
Method:

Replace Class labels of D with Normal and Attack;
Derive model, M using D and Random Forest;
Classify, x_{new} **using** M:
$c = M(x_{new})$; // binary class prediction by M
if $c == normal$ **then**
  return c;
else
  $D_{attack} = \emptyset$;
  for each $x_i \in D$ **do**
    if $x_i \in attack$ **then**
      $D_{attack} = D_{attack} \cup x_i$;
    end if
  end for
  Derive model, M_{attack} **using** D_{attack} **and Random Forest**;
  Classify, x_{new} **using** M_{attack}:
  $c = M_{attack}(x_{new})$; // prediction by M_{attack}
  C = $\{DOS, U2R, R2L, Probe\}$
  for each $k_i \in C$ **do**
    if $k_i == c$ **then**
      for each $x_i \in D_{attack}$ **do**
        if $x_i \in k_i$ **then**
          $D_{new} = D_{new} \cup x_i$;
        end if
      end for
    end if
  end for
  Derive model, M_{new} **using** D_{new} **and Random Forest**;
  $c = M_{new}(x_{new})$; // prediction by M_{new}
  return c
end if

the 3rd International Knowledge Discovery and Data Mining Tools Competition [18], [17]. In this dataset, each data point denotes feature values of a class and every class is labeled either normal or attack and all instances are labeled with one of the five types which are mentioned bellow:

Normal: Normal connections are usually behaviors of the daily normal user and generated by visiting web pages, uploading files, downloading files etc [17].

Denial of Service: DoS attack makes the memory resources or power of a device too full or too busy to serve appropriate networking demands. Denial of service is accomplished by flooding the targeted resource with superfluous requests in an attempt to overload systems [11].

Remote to User: In R2L attack, isolated user achieves access of a native account by transferring packets to a device over the internet, it includes xlock, xnsnoop, guest, sendmail dictionary, phf etc [17].

User to Root: In U2R attack hacker takes access of the system with a normal user account and tries to find vulnerabilities for gaining root-user access. Common example of user to root attacks are perl, buffer-overflows, fd-format, load-module, ffb-config, and xterm [18].

Probing: In Probe attack the hacker scans a networking device or a machine to find known vulnerabilities or gather information [13].

KDD99 dataset have 22 dissimilar sorts of attacks that drop into four central categories and total of 41 input attributes and network connections are divided into three groups and they have discrete or continuous values [18]. The basic attributes of each TCP connections are in the first group, it includes the prototype, duration, bytes quantity of IP addresses of source or IP addresses of destination, some flags in TCP connections, and service. The features of network connections suggested by domain knowledge are in the second group and the third group has the statistical attributes that which are calculated by using a two-second time period. We have used training data to train the classifiers and evaluate the classifier models supplying test data from UCI machine learning repository. In testing data, there are some unknown attack examples those are not available in the training data. The number of training and testing examples are shown in Table I.

TABLE I: Number of instances in KDD99 dataset.

Attack Types	Training	Test
Normal	972781	60593
R2L	1126	7015
U2R	52	39

B. Result

We have implemented the proposed method in Python 3.7 and used scientific Python development environment (Spyder) 3.3.1 (https://www.spyder-ide.org). We have experienced the performance of some popular machine learning algorithms like Random Forest, Bagging, naïve Bayes and ANN on KDD99 dataset. We have supplied testing data for evaluating our proposed method using detect rate and false positive rate. DR is very low for minority class instances which are mostly in R2L and U2R attack types. Some of the strong classifiers like Random Forest, ANN, Bagging, naïve Bayes failed to classify the minority class instances. For our proposed method, we have momentous improvement and DR for minority class instances in our proposed method is above 81%. The proposed method raises detection rates for R2L and U2R attacks type and achieved 87% and 81% detection rate where some popular algorithms able to achieve less than 30%. The improvement of false positive rate also noticeable for our proposed hybrid method. Comparison of results are tabulated in Table II and detection rates of Proposed Method, Random Forest, Bagging, ANN and naïve Bayes are shown in Figure 2.

V. Conclusions & Future Works

Recently, information security has evolved significantly and turn into a vital concern in information technology. IDSs have been employed to protect information from network or host based attacks by utilizing computational intelligence. However, today's accessible IDSs are pattern based also known as misuse

TABLE II: Performance comparison of different strong classifiers with proposed method.

Method	Normal	Probe	DoS	U2R	R2L

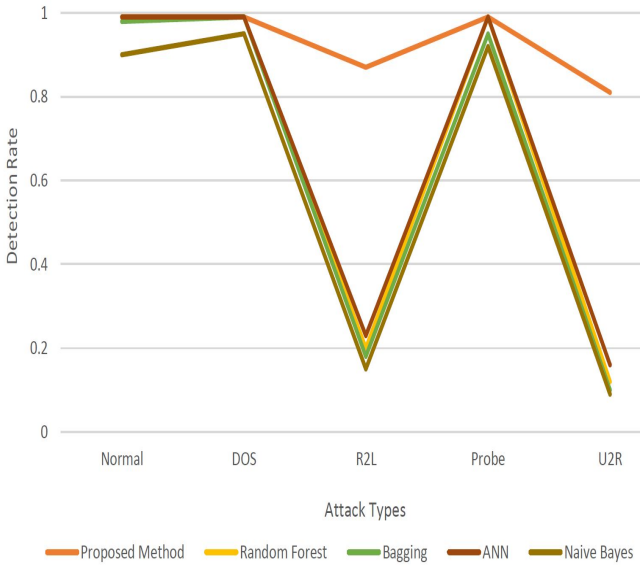

Fig. 2: Detection rates of proposed method, Random Forest, Bagging, ANN, and NB classifier.

based that are not able to detect unknown intrusions. In this paper, we have introduced a new method for improving detection rate to classify minority-class network attacks/ intrusions using cluster-based under-sampling with Random Forest classifier. The proposed method is a multi-layer classification approach, which can process the highly imbalanced big data to correctly identify known or unknown network intrusions. Initially, the proposed method classify a data point/ incoming data is attack/ intrusion or not (like normal behaviour), if it's an attack than the proposed method try to classify attack type and later sub-attack type. We have used cluster-based under-sampling technique to deal with class-imbalanced problem and popular ensemble classifier Random Forest for addressing overfitting problem. The central purpose of this paper is to enhance the detection accuracy of low-frequency attacks in imbalanced network intrusion detection classification. We compared the performance of proposed method with standard data mining algorithms. The experimental results on KDD99 benchmark dataset manifest that the proposed hybrid method raises detection rates and abates false positive rates. The future work will focus on boost the detection rates (DR) of low-frequency attacks in imbalanced dataset and apply this hybrid method into real world NIDS.

Abstract:

A hybrid photovoltaic (PVT) solar thermal system combines a simultaneous conversion of the absorbed solar radiation into electricity and heat. In this study the design of an experimental PVT dual system, both air and water circulation with modifications in the air channel is presented. First modification is to place a thin flat metallic sheet (TMS) inside the air channel and second one is to use painted Black ribbed surfaces at the bottom of the air channel. To observe the variations of heat transmittance with change of the shape of the ribs four experimental setups with a Trapezoidal, Saw teeth forward, a Saw teeth **backward ribbed surfaces and a flat plate have been used. Natural convection is applied instead of forced convection to increase the system's net electrical output & thereby the overall system efficiency. All setups were of the same capacity, projected area, and water heat extraction method and average depth. Performance study was carried out during the months of February to June, 2012 at IUT campus, Gazipur, Bangladesh. Significant performance has been observed with the above stated modifications. In an intense sunny day of March, the maximum temperature of water was found to be 45ºC for Trapezoidal, 44º C for Saw teeth forward, 43ºC for Saw teeth backward and 41ºC for flat plate setup. Maximum temperature of air inside the air channel was found to be 39ºC for Trapezoidal, 38ºC for Saw teeth forward, 37ºC for Saw teeth backward ribbed surfaces and 36ºC for flat plate in an intense sunny day of march 2012 with an ambient temperature of 34ºC. The average efficiency from all calculated values is found to be 64% for Trapezoidal, 62% for Saw teeth forward, 61% for Saw teeth backward and 58% for flat plate setup.**

Keywords— Hybrid thermal system, solar thermal, solar photovoltaic

I. INTRODUCTION

The need for alternative energy sources is getting urgent, hence the development of renewable energy is moving fast. Solar energy is an important clean, cheap and abundantly available renewable energy. The earth receives an incredible supply of solar energy. Different Photovoltaic cell converts only 5-15% of the incoming solar radiation into electricity, with the greater percentage converted into heat. The solar radiation converted into heat increases the temperature of the PV modules, resulting in the drop of their electrical efficiency. This undesirable effect can be partially avoided by applying a suitable heat extraction mode with a fluid circulation, keeping the electrical efficiency at a satisfactory level. Furthermore, this extracted heat can be utilized for heating water. For this purpose the concept of Hybrid photovoltaic/ thermal (PV/T or PVT) solar systems developed. The PV modules that were (are) combined with thermal units, where circulating water of lower temperature than that of PV modules was heated to constitute the Hybrid PVT solar systems. It provides electrical and thermal energy, increasing therefore the total energy output from PV modules using the same projected area. The objectives of this study are to carry out an experimental investigation to compare the performances of four PVT collectors having three different ribbed surfaces (Trapezoidal, Saw teeth (tooth) forward, Saw teeth backward rib) and a flat plate opposite to each absorber plate. All collectors were of same capacity, projected area, and average depth.

Many theoretical and experimental works have been carried out for the improvement of hybrid PVT solar systems since its appearance in 1980's. Among the first who provided the main concepts of these systems with results, by the use of water or air as heat removal fluid. Bhargava *et al.* [1] present results regarding the effect of air mass flow rate, air channel depth, length and fraction of absorber plate area covered by solar cells (packing factor, PF) on single pass, Sopian *et al.* [2] on single pass and double pass hybrid PVT system performance. Garg and Adhikari [3] present a variety of results regarding the effect of design and operation parameters on the performance of air type PVT systems.

In the above works the calculated thermal efficiencies of liquid type PVT systems are in the range of 45% to 65%, the higher values derived for systems that include thermal losses suppression by using air gap with glazing. Regarding air type PVT systems, the thermal efficiency depends strongly on air flow rate, air duct depth and collector length. For higher values of air flow rate, small air duct depth and long PVT systems thermal efficiencies up to about 55% are given by the theoretical models. The packing factor is an important parameter in most of the above papers.

Because of their easier construction and operation, hybrid PVT systems with air heat extraction are more extensively studied, mainly as an alternative and cost effective solution

to building integrated PV (BIPV) systems. Following the above referred studies, test results from PVT systems with improved air heat extraction are given by and from roof integrated air-cooled PV modules by present design and performance studies regarding air type building integrated hybrid PVT systems.

The building integrated photovoltaic is going to be a sector of a wider PV module application in future. The works on building integrated air-cooled photovoltaic include the studies on the multi-operational ventilated PVs with solar air collectors, the ventilated building PV facades and the design procedure for cooling air ducts to minimize efficiency loss [4, 5].

Despite these improvements, commercial application of PVT/air collectors is still marginal, but it is expected to be wider in the future where many building facades and inclined roofs will be covered with photovoltaic. PVT/water systems are more expensive than PVT/air systems due to additional cost of the thermal unit with the pipes for the water circulation. On the other hand water from mains does not often exceeds 25^0C and ambient air is usually higher during summer in low latitude countries and water heat extraction is of more practical value at these locations as it can be used during all seasons. The liquid type hybrid PVT systems are less studied than air type systems.

Regarding recent works, modeling results [6], the study on domestic PVT systems [7] can be referred. PVT/ water collectors can replace thermal collectors for water heating in the domestic and industrial sectors, but they are not yet cost effective and this is the main reason for their niche market penetration.

An experimental study of facade-integrated photovoltaic/water-heating system has been reported done by Chow *et al.* [8]. This work describes an experimental study of a centralized photovoltaic and hot water collector wall system that can serve as a water pre-heating system. Collectors are mounted at vertical facades. Different operating modes were performed with measurements in different seasons. Natural water circulation was found more preferable than forced circulation in this hybrid solar collector system. The thermal efficiency was found 38.9% at zero reduced temperature, and the corresponding electricity conversion efficiency was 8.56%, during the late summer of Hong Kong.

In China, the energy performance of PV/water-heating collector systems with natural circulation of water has been examined by the authors Chow *et al.* [9, 10] based on the weather conditions of Hong Kong and Hefei. These studies showed that the use of a flat-box type thermal absorber is very effective. In Hong Kong for a stand-alone PVT collector system with mono-crystalline solar cells, the daily thermal efficiency was found 48.3% in winter and 45.4% in summer at zero reduced temperature (i.e. when the initial water temperature in the storage tank is as cold as the mean ambient temperature on the day of measurement). This was for water storage to collector-area ratio (M/Ac) of 96.6 kg/m^2 and at a desirable tilt angle.

Design and performance improvements of hybrid PVT systems with water or air as heat removal fluid have been carried out at the IUT including modifications that contribute to the decrease of PV module temperature and to improve the total energy output (electrical and thermal) of the PVT systems [11]. Two systems (PVT/UNGLAZED and PVT/GLAZED) were tested outdoors, consisted of pc-Si PV modules and heat exchanger of copper sheet with copper pipes. Also, PVT solar water heaters of ICS [12] and of thermosiphonic type have been studied.

Tripanagnostopoulos [13] at the University of Patras, Greece has done an extended research on PVT systems aiming at the study of several modifications for system performance improvement. A new type of PVT collector with dual heat extraction operation, either with water or with air circulation is presented. Experiments with dual type PVT models of alternative arrangement of the water and the air heat exchanging elements were performed. The most effective design was further studied, applying to it low cost modifications for the air heat extraction improvement. The modified dual PVT collectors were combined with booster diffuse reflectors, achieving a significant increase in system thermal and electrical energy output.

The present work studied for performance of Hybrid Photovoltaic Thermal (PVT) dual solar collector using different ribbed surfaces placed opposite to the air channel wall. Tests were carried out in the months of February to June, 2012 at IUT campus, Gazipur, Bangladesh.

II. Experimental Setup

Four experimental setups were fabricated with similar design and dimensions except the shape of the ribs. All works were done in the Mechanical Workshop of Islamic University of Technology (IUT), Gazipur, Bangladesh. The whole setup was constructed in a wooden box. PV panels were set at the top of the box. Thin Metallic Sheet (TMS) was placed at the middle part of the box on top of which pipes were set for water circulation. Air channel of 0.1m height was kept under the water heat exchanger. Different ribbed surfaces (*Trapezoidal, Saw* **teeth** *forward, and Saw* **teeth** *backward) and a Flat plate* of same height and dimension were placed on opposite wall of the air channel. The whole inner portion of the box was insulated. TMS and

Ribbed plates were painted black for better heat absorption. Fig . 1 shows the schematic diagram of each experimental setup with different ribbed surfaces. Details of hybrid collector and test specimens used in this study are shown in Fig. 2 and in Fig .3.

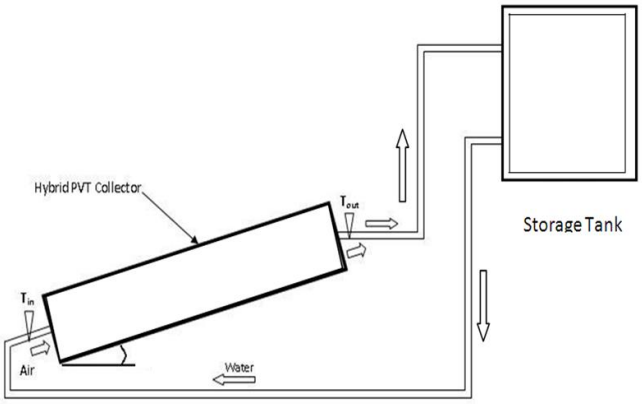

Fig. 1: Schematic diagram of the experimental setup.

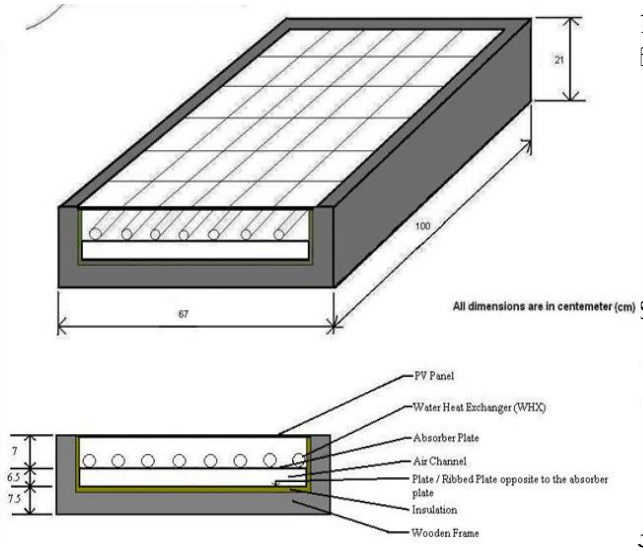

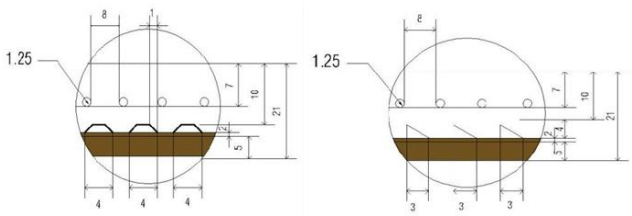

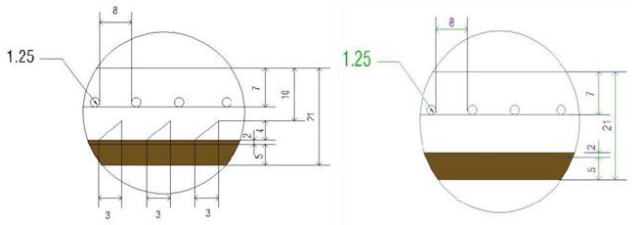

Fig . 2: Details of Hybrid Collector. (All dimensions are in cm)

A. *Test procedures:*

All the collectors were installed in front of the IUT workshop where there is no obstacle to sunshine and faced towards south with an inclination angle of 23.5^0 which is the best angle to collect as much as available radiation. Photograph of which are shown Fig . 1. All storage tanks were filled early in the morning with fresh water. Temperatures were measured for PV panel (T_{PV}) and water heat exchanger (T_{WHX}), by using seven 36 S.W.G. Chromel-Alumel thermocouples. Selector switches were used to switch between the thermocouples. Ambient temperatures (Tamb), solar radiation (G) were recorded hourly each day from at 8 AM up to 6 PM. All readings were recorded in specific data sheets.

(a) Trapezoidal rib (b) Saw teeth forward rib

(c) Saw teeth backward rib (d) Flat plate

Fig 3: Test specimens. (All dimensions are in mm)

B. *Equations used*

To calculate the thermal efficiency (η_{th}) of the collector the following equations are used:

Heat energy absorbed at any time for the projected area,

$$Q_{ab} = m \times C_p \times \Delta T_w / A_a \quad (Wm^{-2})$$

Here, ΔT_w is the temperature difference between inlet and outlet of water.

Solar radiation received in that time for the projected area, G (Wm^{-2})

So thermal efficiency can be found from, $\eta_{th} = Q_{ab} / G$

III. Results and Discussions

Performance study of four hybrid PVT systems were carried out in IUT Campus, Gazipur, Bangladesh during the months of February to June 2012. PV panel temperature and water heat exchanger surface temperature were recorded and plotted against time. These are presented from Fig. 4 to Fig. 13. Thermal efficiency is calculated for all the setups and average plotted in and presented in Fig. 14. Thermal output is emphasized more than the electrical output in this study. As no electrical load is used as a part of the setup, output from PV panel is not hampered.

A. *PV panel temperature*

Temperature distributions of PV panels of different setups with time are shown in Fig.4 to Fig. 8. As the PV panel receives the solar energy directly on top of the setup, panel temperature rises very quickly with time. The figures shows similar patterns of temperature survey with slight difference among four setups. PV panel temperature rises from 8:00 am to 12:00 noon and then decreases after 2:00 pm rapidly. In a sunny day of 15 February 2012, the maximum temperature of PV panel is found 61ºC for Flat plate, 57ºC for

Trapezoidal, 57ºC for Saw teeth forward and 59ºC for Saw teeth backward plate. In a sunny day of 30th February 2012 the maximum temperature of PV panel is found 60ºC for Flat plate, 56ºC for Trapezoidal, 57ºC for Saw teeth forward and 58ºC for Saw teeth backward plate. In an intense sunny day of 15 March 2012, the maximum temperature of PV panel is found 62ºC for Flat plate, 56ºC for Trapezoidal, 57ºC for Saw teeth forward and 59ºC for Saw teeth backward plate. In a sunny day of 30March2012, the maximum temperature of PV panel is found 62ºC for Flat plate, 56ºC for Trapezoidal, 57ºC for Saw teeth forward and 60ºC for Saw teeth backward plate. In a sunny day of 15 April 2012, the maximum temperature of PV panel is found 62ºC for Flat plate, 55ºC for Trapezoidal, 56ºC for Saw teeth forward and 59ºC for Saw teeth backward plate. In a sunny day of 30April2012, the maximum temperature of PV panel is found 61ºC for Flat plate, 54ºC for Trapezoidal, 56ºC for Saw teeth forward and 59ºC for Saw teeth backward plate. In a partly cloudy day of 15 May 2012, the maximum temperature of PV panel is found 40ºC for Flat plate, 44ºC for Trapezoidal, 43ºC for Saw teeth forward and 42ºC for Saw teeth backward plate at the time was 02:00 PM. In a Rainy day of 30 May 2012, the maximum temperature of PV panel is found 40ºC for Flat plate, 41ºC for Trapezoidal, 40ºC for Saw teeth forward and 39ºC for Saw teeth backward plate. In an intense sunny day of 15 June 2012, the maximum temperature of PV panel is found 64ºC for Flat plate, 63ºC for Trapezoidal, 62ºC for Saw teeth forward and 60ºC for Saw teeth backward plate. In a sunny day of 30June 2012, the maximum temperature of PV panel is found to be 62ºC for Flat plate, 61ºC for Trapezoidal, 60ºC for Saw teeth forward and 59ºC for Saw teeth backward plate.

Setup with Saw teeth forward and Saw teeth backward ribs setup gave lower temperature of the panel which shows better cooling of PV. Trapezoidal ribbed plate gave moderate cooling better than that of flat plate setup. In flat plate setup PV temperature is found always high, which shows inadequate heat transfer for PV cooling.

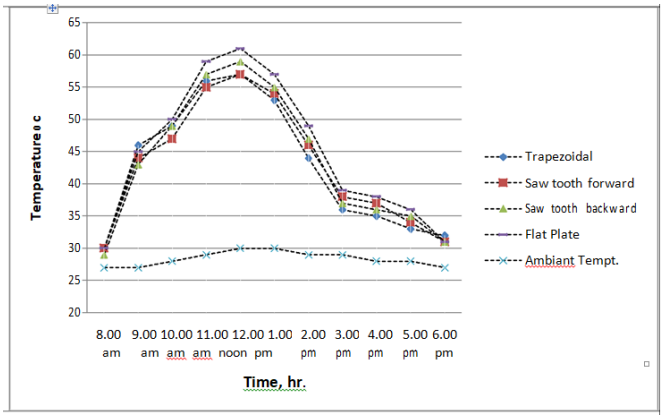

Fig. 4: Temperature distribution of PV panel temperature on 15/02/2012

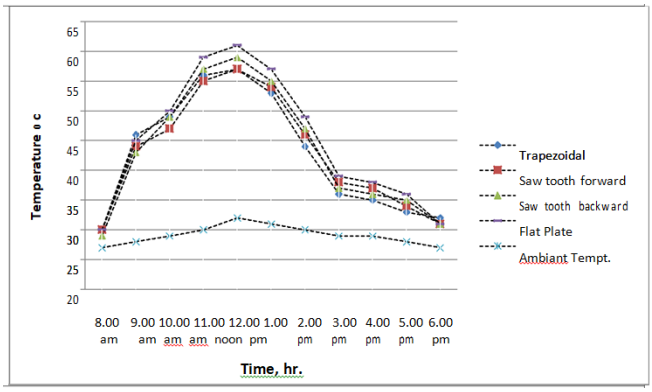

Fig. 5: Temperature distribution of PV panel temperature on 15/03/2012

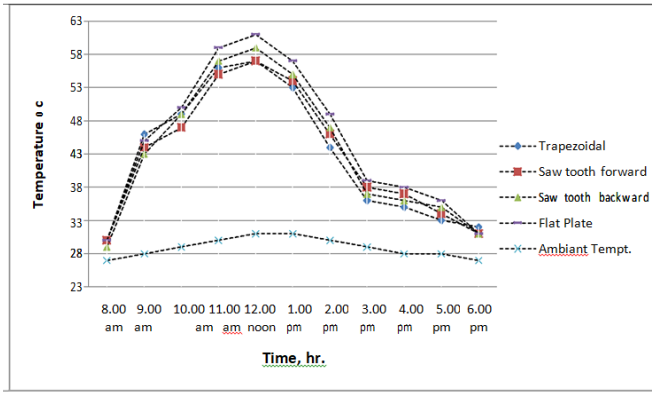

Fig. 6: Temperature distribution of PV panel temperature on 15/04/2012

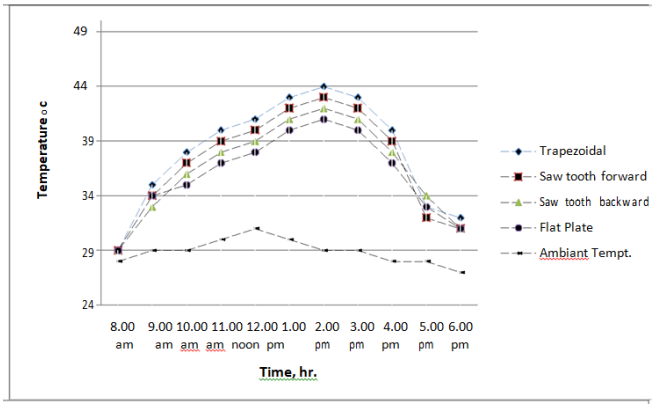

Fig. 7: Temperature distribution of PV panel temperature on 15/05/2012

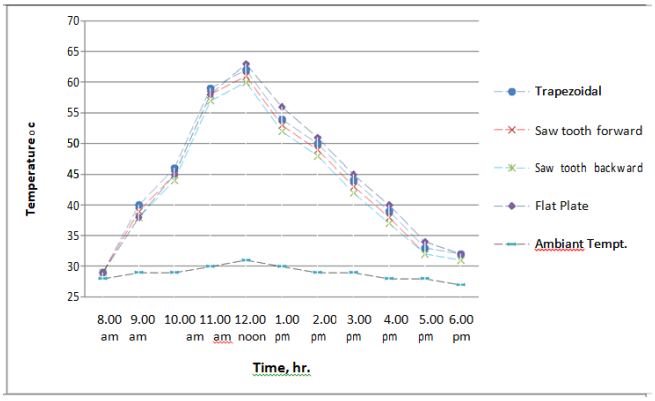

Fig.8: Temperature distribution of PV panel temperature on 15/06/2012

B. Water Heat Exchanger temperature

Water Heat Exchanger (WHE) surface temperature distributions of different setups with time are shown in Fig. 9 to Fig. 13. Water heat exchanger with TMS is placed below the PV panel at the middle section of the setup. Heat energy is absorbed here from the PV rear surface and water is heated flowing through it. It is evident from these figures that the temperature of this heat exchanger also rises with time from 8:00 am to 12:00 noon and then decreases after 2:00 pm rapidly. In a sunny day of 15February 2012, the maximum temperature of WHE is found 50ºC for Flat plate, 48ºC for Trapezoidal, 49ºC for Saw teeth forward and 51ºC for Saw teeth backward plate. In a sunny day of 30 February 2012 the maximum temperature of WHE is found 49ºC for Flat plate, 46ºC for Trapezoidal, 50ºC for Saw teeth forward and 48ºC for Saw teeth backward plate. In an intense sunny day of 15March 2012, the maximum temperature of WHE is found 48ºC for Flat plate, 46ºC for Trapezoidal, 49ºC for Saw teeth forward and 47ºC for Saw teeth backward plate. In a sunny day of 30March 2012, the maximum temperature of WHE is found 48ºC for Flat plate, 46ºC for Trapezoidal, 49ºC for Saw teeth forward and 48ºC for Saw teeth backward plate. In a sunny day of 15April 2012, the maximum temperature of WHE is found 49ºC for Flat plate, 52ºC for Trapezoidal, 52ºC for Saw teeth forward and 49ºC for Saw teeth backward plate. In a sunny day of 30 April 2012, the maximum temperature of WHE is found 49ºC for Flat plate, 47ºC for Trapezoidal, 51ºC for Saw teeth forward and 49ºC for Saw teeth backward plate. In a partly cloudy day of 15 May 2012, the maximum temperature of WHE is found 36ºC for Flat plate, 38ºC for Trapezoidal, 37ºC for Saw teeth forward and 36ºC for Saw teeth backward plate at the time was 02:00 PM. In a Rainy day of 30 May 2012, the maximum temperature of WHE is found 34ºC for Flat plate, 37ºC for Trapezoidal, 36ºC for Saw teeth forward and 35ºC for Saw teeth backward plate. In an intense sunny day of 15 June 2012, the maximum temperature of WHE is found 45ºC for Flat plate, 48ºC for Trapezoidal, 47ºC for Saw teeth forward and 46ºC for Saw teeth backward plate. In a sunny day of 30 June 2012, the maximum temperature of WHE is found 45ºC for Flat plate, 47ºC for Trapezoidal, 48ºC for Saw teeth forward and 46ºC for Saw teeth backward plate. Average good temperature is found in case of setup with Saw teeth forward rib. Average temperature difference between PV panel and WHE is around 10-12ºC.

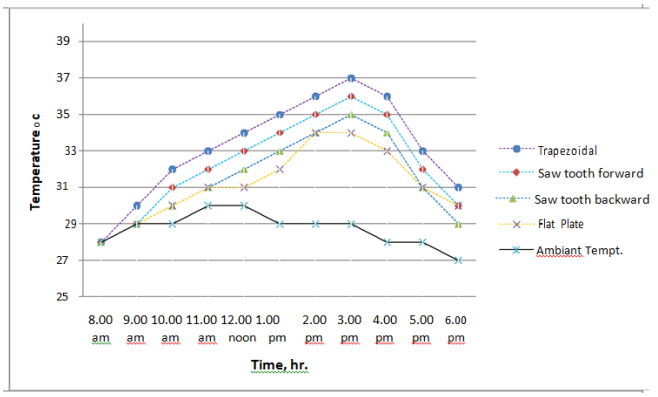

Fig. 12: Temperature distribution of water heat exchanger temperature on 15/05/2012.

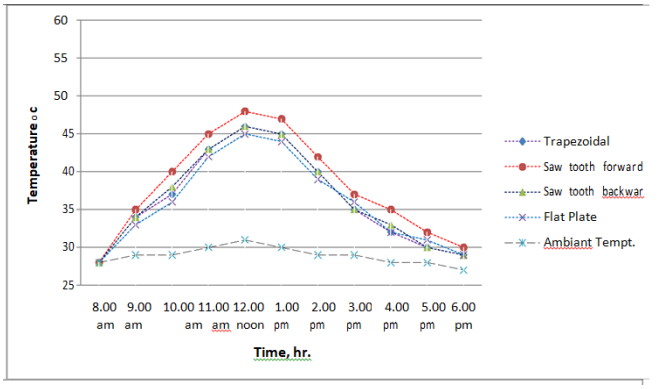

Fig. 13: Temperature distribution of water heat exchanger temperature on 15/05/2012.

C. *Thermal efficiency comparison*

Thermal efficiency regarding water is compared as a function of $\Delta T/G$ ($Kw^{-1}m^2$).ΔT is the temperature difference between input fluid and the ambient temperature. Efficiency of all four setups is compared along with the work of Tripangnostopoulos (2007) and Rezwan (2011) in Fig. 14 for comparison. Tripangnostopoulos studied a hybrid PVT/dual system having corrugated rib on opposite air channel with WHE placed just under the PV panel in 2007 at the University of Patras, Greece. .Karim and Akhanda (2011) studied hybrid photovoltaic thermal solar system using three different rib surfaces (Triangular, Semicircular, and Square) and flat plate in 2011 at IUT.

The present study was carried out using hybrid photovoltaic thermal solar system using three different ribbed surface (Trapezoidal, Saw teeth forward, Saw teeth backward) and a flat plate in 2012 at IUT, Bangladesh. The efficiency of Trapezoidal is 36% to 73%, Saw teeth forward is 37% to 70%, Saw teeth backward is 36% to 67% and Flat plate is 33% to 59%. Tripangnostopoulos (2007) PVT system is found to vary from 45% to 62% and Rezwan (2011) reported results to vary from 35% to 70%. The average efficiency from all calculated values in the present study is found to be 67% for Trapezoidal, 62% for Saw teeth forward, 61% for Saw teeth backward and 54% foe flat plate setup.

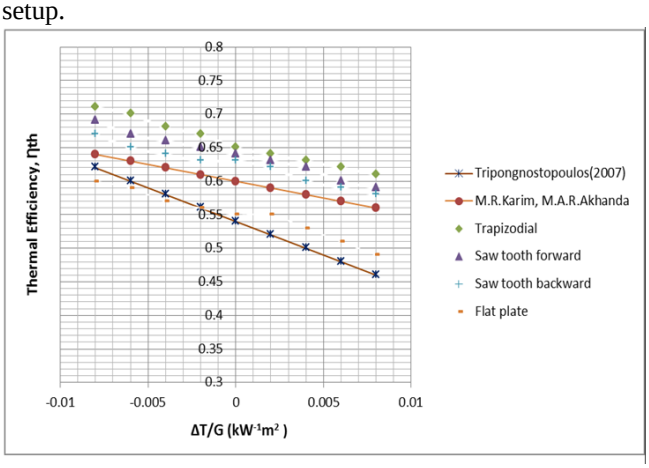

Fig. 14: Comparison of thermal efficiencies of all four systems.

The range of efficiency varies with the operating temperature of the system. The thermal efficiency of PVT/dual system for water heat extraction is extended in negative $\Delta T/G$ axis, as some experiments were performed for ambient temperature being higher than the water temperature at system input. Data taken for comparisons of setups are similar with $\Delta T/G$ values, to make the comparison more correct.

IV. Conclusions

From this experimental study the following conclusions are drawn;

- With the increase of PV panel temperature the water temperature also increase and reach a maximum value at a maximum PV temperature around noon. The temperature then decrease slowly with the ambient temperature.
- The energy absorbed in the system from 8AM to 12 Noon is faster than that absorbed in the afternoon for all systems, tested in this study.
- Average water temperature rise is found to be better in Trapezoidal and Saw teeth forward ribbed surface then those of surfaces with Saw teeth backward and Flat plate. Setup with Saw teeth forward ribbed surface shows better performance than that of Flat plate but its average performance is lower than that of setup with Trapezoidal and Saw teeth forward ribs.
- Thermal efficiency is found to be the best in the setup with Trapezoidal ribs among all setups, applying similar experimental conditions (T/G). Efficiency of Saw teeth forward, saw teeth backward and flat plate is also found satisfactory within the range of experimental conditions.
- PVT/dual system can be used to heat water depending on the weather conditions and building needs. The water heat extraction part could operate mainly during periods of higher ambient temperature and the air heat extraction part to operate mainly when the ambient temperature is low. In mild weather conditions (like Bangladesh) it is possible to operate both heat extraction modes, if it is considered useful for the application.

***Abstract*—In this paper, seizure activities of EEG signals have been detected exploiting 1-D convolutional neural network architecture of deep learning algorithm. In past some years, many algorithms have been developed for seizure detection. Traditional method of seizure detection includes manual feature selection and classifier separately. In recent years, convolutional neural network architecture of deep learning gets very much popularity in place of traditional method.Though, very few works of convolutional neural network are found in literature for one dimensional signal classification. However, one dimensional EEG and ECG signal classifications are necessary to detect and investigate diseases like seizure activity, sleep apnea or arrhythmia and so on. The proposed method of one dimensional EEG signal classification for epileptic seizure detection involves the smallest and simplest 1-D convolutional neural network architecture for automated feature selection. The projected architecture is implemented to detect several kinds of seizure and non-seizure EEG signals and found achieving greater accuracy and sensitivity in comparison to that acquired by state-of-the-art methods involving manual feature selection and the identical EEG dataset.**

***Keywords*—Electroencephalogram (EEG), epilepsy, seizure, 1-D convolutional neural network (CNN)**

I. Introduction

There are many types of seizures. Seizure types depend on where and how they begin in the brain. Mostly they sustain from 30 seconds to two minutes. It is an emergency situation if any person is attacked by seizure and the duration is more than five minutes. Seizures are more common disease. Seizures can happen for many reasons. Among the reasons, some are person experiencing head injury, brain infection, stroke, fever and many other health problems. But still, when a person is attacked by seizure, cause cannot be defined accurately [1].

Many processes or algorithms have been used to detect seizure. As we see in traditional methods, features have to be extracted from the EEG signal. Normal Inverse Gaussian (NIG) statistical modeling parameters or higher order statistics (HOS) have been used as features for EEG signal. These features have been analyzed in Empirical Mode Decomposition (EMD) domain or in Discrete Wavelet Transform (DWT) domain. However, no specific IMF or time-frequency band has been mentioned in these works and thus increased the size of feature set and computational burden. Then classifier like SVM or ANN hve been used to detect the seizure from the normal EEG signal. These are actually lengthy process as well as time consuming method [2], [3], [4]. So, we have been motivated in this work to use Convolutinal Neural Network (CNN) scheme for detection and classification of seizure and non-seizure 1D EEG signal which will replace the above mentioned lengthy and time consuming methods with automatic feature selections.

In recent years, the deep learning with CNN architecture for automatic feature selection is gathering popularity in signal processing. This method involves fast computation as the manual feature and classification step are not done here. EEG signal has the feature of low frequency signal for long time period and the feature of high frequency for small time period. There is a kind of hierarchy among these features of EEG signal. Deep learning is also known as hierarchical learning which encodes hierarchy of features. So for EEG signal classification, we are proposing deep learning based method.

The paper is arranged as follows: we have presented in section II method description; in section III results & analysis which includes dataset description, goodness of features, performance assessment & comparison of proposed and existing methods; and in section IV conclusions.

II. Method Description

The sequence of EEG signal ranges up to 60 Hz [5]. 60 Hz above of an EEG signal are noise. The noise of EEG signal has been removed by passing the signal over a 6th order Butterworth filter. The cutoff frequency of the low pass filter has been selected 60 Hz.

In this paper, we have used convolution neural network method. This method is replacing the traditional & manually selecting feature extraction and classification steps.

CNN model automatically reads the pattern of EEG signal from the data and performs classification. On the other hand in traditional approach, at first features are extracted, major features are separated and then a classifier is used for classification. Full traditional approach is a manual process. But through CNN, the scheme is fully automated.

A CNN has three layers. One input layer, one output layer and multiple hidden layers. The CNN architecture consists of convolutional layers, maxpooling layers and fully connected layers. In these layers, unknown number of mathematical

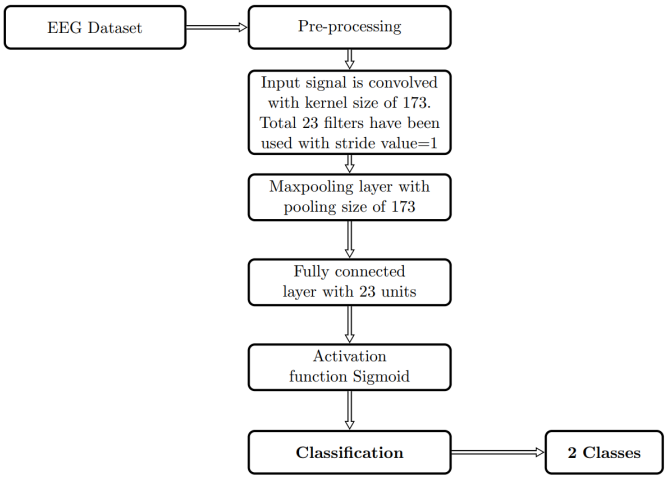

Fig. 1: The Proposed Model Architecture

operations are being performed.

CNN model is based on convolutional process. The considered data signals are seizure and the non-seizure EEG signals. Each time two different data-class has been considered for analysis of this work. The input signal is convolved with the selected kernel size 173. Total 23 numbers of filters has been considered in each analysis of 2 classes. The kernel size of 173 and 23 number of filters have been selected because the sampling rate of EEG signal is 173.61. The length of input signal is 4097 as the sampling rate is 173.61 and the each set data segments are of 23.6 seconds. After each convolution operation, the output data contains the feature map of the input signal. Here, stride is selected at 1.

Down sampling operation is performed in max pooling layer. Performing max pooling layer on the output of the convolutional layer reduces the dimension of the output neuron. Through this layer, maximum value has been selected from the output feature maps.Max pooling size is set in this work equal to the kernel size that is 173. So, this down sampling operation consequently reduces the computational intensity. After that, the output from max pooling is flattened out and the output is applied as the input for the fully connected layer (FC). FC layers are 1D vector. FC layer see the output of the previous layer.At first, fully connected layers are set to 23 which is equal to the number of filters. In the next step, FC layers are set to 2. It actually works as the classifier. This layer determines the features correlating to a particular class.

Two activation functions have been used in this paper. One is sigmoid and another is softmax. These are non linear functions. Activation functions are used as a decision maker as activation function activates or fires a neuron from the output of fully connected layer. Activation function sigmoid is used which thresholds at zero. Thus, it keeps the volume unchanged. This layer increases the nonlinear properties of the model. The methodology used in this paper is presented in Fig 1.

III. Results and Analysis

A. Dataset Description

For analyzing, we have used the EEG signal data from Bonn university seizure database [6] and proposed CNN for epileptic seizure detection. Dataset description are as follows:

Recorded data has been collected by placing 10-20 electrodes which is an internally recognized standard system. In the database, there are five data sets. The notations for five data sets are declared as A to E. The EEG signals of each set has been recorded by 128 amplifier system. The data available in each set are 100 single channels EEG segments with duration of 23.6 seconds. Set A consists of those EEG data segments which have been recorded at relaxed with awaken state and eyes open. Set B consists of those EEG data segments which have been recorded at relaxed with awaken state and eyes closed. Both A and B sets data are of five healthy volunteers. The EEG signal segment in set C, D & E have been taken from 5 seizure patients. Sets C, D and E have been taken from EEG archive of pre-surgical diagnosis. EEG signal segments in D set have been recorded from the epileptogenic zone during seizure-free intervals. On the other hand, EEG signal segments in C set have been recorded from hippocampal formation of opposite hemisphere of the brain during seizure-free intervals. E set is found solely with the recording of those EEG signal segments of the patients undergoing epilepsy .

The data acquiring process of EEG signal involves sampling rate of 173.61 Hz and 12 bit analogue-to-digital converter. From the visual examination of continuous multichannel EEG recordings, the band pass filter of 0.5340 Hz (12 dB/oct) has been used to remove the desired segments.

In this investigation, we have used all the five datasets from A to E of Bonn university seizure database. The CNN has been done using keras neural network library. We have run the code to differentiate between 2 classes of EEG signals: A-E, B-E, C-E, D-E, ABCD-E & A-C. Figure II-VI show the raw EEG signals of the above mentioned pairs which are required to be classified. It is well-understood from the figures that without extracting appropriate features, it is very difficult to differentiate the classes from the raw EEG signals.

Training set and the testing set are not definitely defined. For binary classification, randomly fifty percent of the total segments are selected for training purpose and the rest fifty percent are selected for testing purpose. Ensuring the performance of the adopted methodology and the system for each binary classification, the methodology has been run for 10-times randomly for cross checking. As a result, this step ensures the unbiased performance of the adopted methodology as the each time randomly different sets of training and testing sets have been automatically selected. Standard deviation has been calculated for each binary classification which shows the deviation of the ten sets of results.

B. Goodness of Features

The features extracted by CNN architecture have been exploited to understand the features quality by Geometrical Separability Index (GSI) and Bhattachariya Distance (BD)

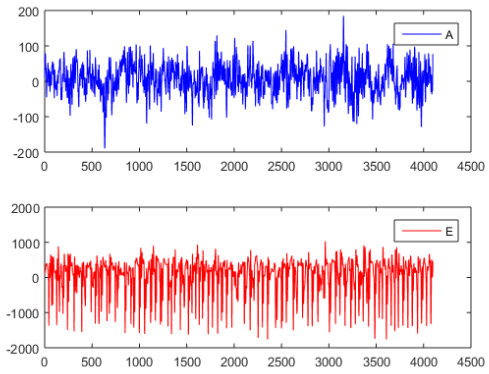

Fig. 2: Time Domain Plot of A and E Classes of EEG Signals

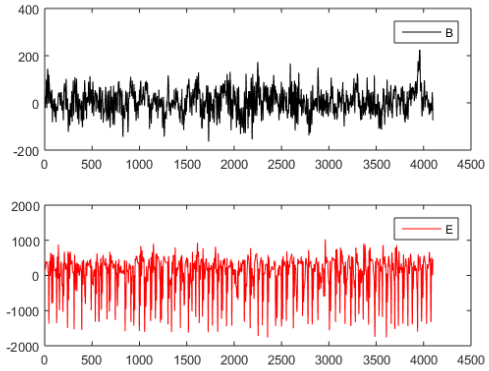

Fig. 3: Time Domain Plot of B and E Classes of EEG Signals

value [4]. GSI and BD values are two measures of inter-class distance and intra-class compactness; respectively. To which extent two classes can be distinct together in the neighboring sense is indicated by GSI value. The 0 GSI value directs two class as inseparable while the GSI value greater than 0.5 estimates two classes as detachable.

Intra-class compactness of clusters is shown by BD value. The smaller BD value postulates more compactness of the features in similar class. The GSI and BD values for mentioned all five classes in the dataset are shown in Table I and Table II.

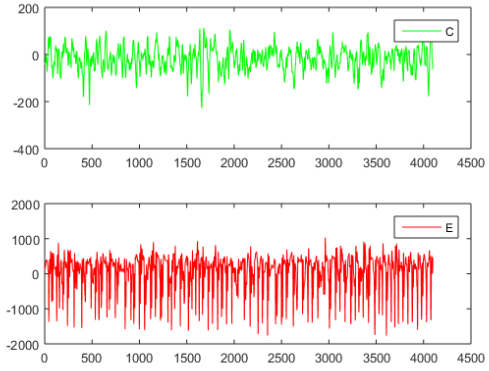

Fig. 4: Time Domain Plot of C and E Classes of EEG Signals

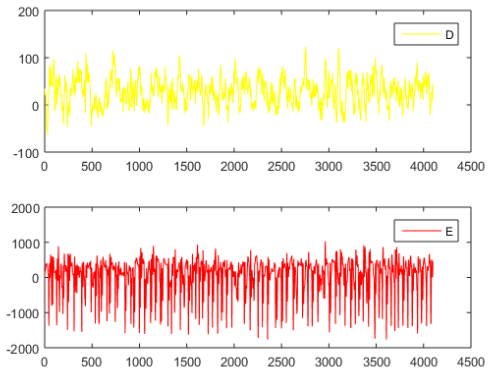

Fig. 5: Time Domain Plot of D and E Classes of EEG Signals

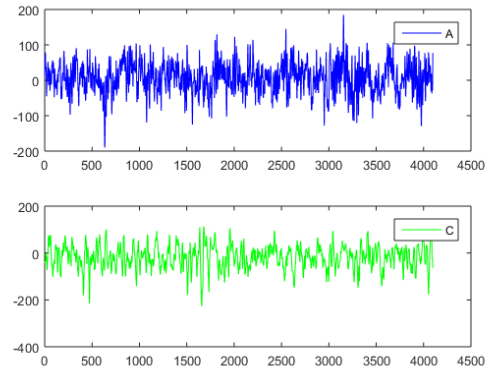

Fig. 6: Time Domain Plot of A and C Classes of EEG Signals

TABLE I: GSI VALUES OF THE PROPOSED SCHEME

Class	A	B	C	D	E
A	0.04	0.90	0.81	0.90	0.93
B	0.90	0.33	0.96	0.95	0.50
C	0.81	0.96	0.4	0.98	0.98
D	0.90	0.95	0.98	0.36	0.95
E	0.93	0.50	0.98	0.95	0.42

TABLE II: BD VALUES OF THE PROPOSED SCHEME

A	B	C	D	E
0.0193	0.0389	0.0487	0.0951	0.0583

C. Performance Assessment

To evaluate the performance of the proposed model, accuracy with standard deviation and sensitivity has been calculated. Accuracy with standard deviation and sensitivity results for binary classificatinons are stated in Table III, Table IV, Table V , Table VI, Table VII & Table VIIII. The following equations have been used for the analysis of the output result

TABLE III: PERFORMANCE RESULT FOR CLASS A-E

Methods	Sensitivity% for A%	Sensitivity% for E	Accuracy% ± Avg STD
Scheme of ref [3] using HOS parameters	76.6	99.3	87.9
Scheme of ref [2] using NIG parameters	97.5	94	95.75
Proposed CNN structure for classes A-E	98.80	100	99.4±0.52

of proposed model [7]:

$$\text{Sensitivity}_i = \frac{TP_i}{TP_i + FN_i} \times 100\% \quad (1)$$

$$\text{Accuracy}_i = \frac{TP_i + TN_i}{TP_i + TN_i + FP_i + FN_i} \times 100\% \quad (2)$$

All these are calculated in percentage. In the above equation TP stands for true positive, TN stands for true negative, FP stands for false positive and FN stands for false negative.

D. Comparison of Proposed and Existing Methodology

The methodology used in this paper is very simple CNN architecture . Accuracy result for A-E through the proposed methodology is 99.4% which is an improved result from the EMD based methodology in scheme of reference [3]. Accuracy result for D-E is 99.4% which is higher than the accuracy found through EMD based methodology in scheme of reference [3]. The sensitivity & the standard deviations are presented in Table III to Table VIII.

In some paper, it has been found that dual-tree complex wavelet transform has been used with features obtained from five sub-bands gamma, beta, alpha, theta and delta. And after that separately SVM classifier has to be used for classification [2].

The absorbed methodology in this paper used only single layer of max pooling layer and two layers of fully connected layer. So, definitely the time for running the code gets reduced as well as the complexity of CNN architecture has also been reduced. If we see other works on CNN methodology, it is found that complex CNN architecture are adopted like three or four convolutional layer, three or four FC layer etc [8]. These architectures are time consuming as the computational time and complexity of these architectures are higher than the proposed methodology.

In this paper, the binary classification has been performed for A-C & B-E class. The scheme of reference [2] and the scheme of reference [3] have not been used for the binary classification of A-C & B-E class. But in this paper, all the binary classification has been performed from class A to class E with a better accuracy result.

It is experimented that steps in proposed CNN architecture can differentiate two classes of seizure with minimal time and also replacing the EMD based analysis and wavelet transformation based analysis with better experimental result.

IV. CONCLUSION

We have explored the proposed method for 1-D signal. The computational complexity has been very much reduced through the proposed method of CNN architecture and the accuracy is found satisfactory. So it can be a preferable methodology for seizure classification.

TABLE IV: PERFORMANCE RESULT FOR CLASS B-E

Methods	Sensitivity% for B	Sensitivity% for E	Accuracy% ± Avg STD
Proposed CNN structure for classes B-E	99.60	99.80	99.7 ±0.48

***Abstract*—In the perspective of the Bangladesh garment industry, a vast amount of power is wastage due to forgetting in turning off the machines at break time or other reason. Also, the existing prepaid meter doesn't include any system to understand the wastage of the power and control the machines remotely. This research demonstrates a smart energy meter to understand the idle use of the loads and control the loads remotely. This efficient and cost-effective system offers an accurate estimation of the consumed power and cost, reducing the labor cost. A microcontroller is involved in calculating the voltage, current, energy and cost. After deploying in the garment industry, the first few daysthe systemmeasures the consumed amount of power by different loads and store it. From these values, an average value is estimated as a threshold value for that load. In case of exceeding the threshold value of this load, an auto-notification is sent to the authority via a GSM module. Being notified about the excessive usage via that load, the authority confirms about the machine is in working state or idle state through announcing in a microphone. According to the response, the authority takes the decision and sent a specific command through SMS to the system. The GSM module converts the SMS into a signal that is supplied to the microcontroller to turn off the load. In consequence of this feature, the system will assist the authority of the garment industry to be economical in power consumption, and the amount of power wastage will be reduced drastically.**

Keywords—smart energy meter, GSM module, Arduino Uno,

I. INTRODUCTION

Electricity is the prime source of economic development for most of the country. According to the WorldData total consumption of electric energy is 53.65 billion kWh per year where per capitaaverage is 326 kWh in Bangladesh [1].Bangladesh Power Development Board (PDB) stated that 90% of the population had access to electricity[2]. However, per capita energy consumption in Bangladesh is considered very low. Power deficiency is the most significant issue for any developing country in the world. Without proper administration of power use, it is almost difficult to reduce power deficiency, keep up proper billing and increase client satisfaction. A massive amount of electrical energy, a real scenario presented in figure 1, requires for moving forward the garment industry of Bangladesh. Also, lots of energy is wasted just because of the whimsical of the garment worker by keeping the machine on state while it doesn't assign any task.

In this situation, to remotely control the heavyweight machine while it doesn't assign any task, an automated smart energy meter with better service is in need. The proposed GSM based energy meter needs a few days to observe the amount of the power consumption of the industry. Through this observation data, the system generates some threshold value for each load used in the industry. Later, in case of exceeding this threshold value the authority confirm that anyone is working on that area or not. In case of idle use of the load, the authority turns of the machine.A simple #A.sys on* short message and #A.sys off* message is transmitted to control the meter on and off. So, it will assist the authority to subside the wastage of the power and save a lot of money through this system.

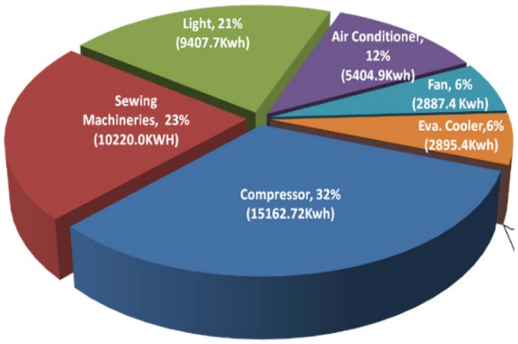

Fig. 1. Power Consumption Scenario inYOUNGONE(CEPZ) Ltd.

The primary objective is to reduce the energy consumption of the garment industries through a smart monitoring system. By monitoring the day to day consumption, the system can easily determine the sudden change in electricity consumption. It will help to avoid any kind of energy wastage in the factory premises.GSM based smart energy meter is already present in the market, but not so cheap and accurate.Also, to show a way of a cheaper alternative smart energy monitoring system is another objective of this research.

The rest of the paper is organized as follows. Section II deliberatesthe related work. In section III methodology including circuit operation, hardware, software, and the

working procedure are explained. Section IV demonstrates an experimental resultwhile section V concludes the paper.

II. Related Work

AMR (Automatic Meter Reading)transfers the unit of used power of the industry or household at a certain period to the central system of a distribution company via wireless communication to produce the monthly bill remotely [3].

The magnitude of the consumed power of various electronic devices is measured in a microcontroller-based smart wattmeter[4]. Digital transformation and signal processing techniques have been utilized to design the meter. As the GSM or GPRS module isn't integrated with this meter, it can't interact with the consumer spontaneously that increases the employment cost. Masum et al. [5] introduced a smart meter for residential customers in Bangladesh that can predict the next day usage by using machine learning regression analysis. In another work, the next day usage had been predicted through Support Vector Regression [6]. Numerous features like meter reading, tempering, power cut information, total used load and disconnect on demand or frequently through SMS alert is combined in an Automatic Meter Reading system for remotely monitoring and controlling purpose [7].The large expense is the major downside of this meter. A summary of previous work has been demonstrated in table 1.

TABLE I. Summary of the Previous Work

Authors & Year	Used Sensor	Methodology	Findings
Riddhi Ghosh [8]	Voltage Sensor & Current Sensor	Smart Energy monitoring through ARM processor	Power quality events can be recorded but no controlling
S.V.Anushree, T.Shanthi[9]	Voltage Sensor & Current Sensor	IOT,DNO, Microcontroller ATMEGA	Electricity theft Prevention
Shivani B. Sonune, R.P. Borole[10]	Current Transformer, Potential Transformer,	Wireless energy metering through radio frequency	Zigbee networking is a cheaper alternative to internet administration for remote control
S Chopra et al. [11]	Voltage sensor & Current Transformer, Peak Detector Circuit	Peak load setting peak load calculation	Meter reading can be collected from remote areas.
Motiur, Fakhrul, Ashiq, Tanver[12]	Current Sensor (ACS712-20A), Optocoupler	IOT, ARDUINO, GSM, and GPRS	Desco meter can be monitored

In the context of Bangladesh, a significant amount of power is waste daily due to the whimsical act of worker, and heavy machines continue to run while it doesn't assign any task at all. Also, there doesn't exist any system to control the load remotely in case of their idle usage. To the best of our insight, this work is the first attempt to subside the wastage of the power of the industry. Through this system, we succeed to minimize a significant amount of energy, showing a case study considering YOUNGONE (CEPZ) Ltd with their legal permission.

III. Methodology

Figure 1 demonstrates a picture of the proposed system how it is designed and worked. After supplying the power, the system is initialized. At the beginning stage, the framework takes a few moments to initialize and estimate the current and voltage. Power is calculated in inductive load as the product of current, voltage and cosine of the angle of the phase difference between current and voltage while in resistive load it is simply a product of current and voltage. There are three types of power which could be measured named real power, apparent power, and reactive power. Among these three types, we have chosen real power consumed in the sewing industry. Real power is measured using equation 1:

$$P = V_{rms} \times I_{rms} \times Cos(Ø)\ Watt \quad (1)$$

Here, P= Power, V_{rms}= Voltage, I_{rms} = Current, Cos(Ø)= Power Factor and Ø= The angle between $V_{rms}$and I_{rms}.

The real power measurement is done accurately anddepending on the load we get either leading or lagging power factor. Determining the phase difference between the line voltage and current is an essential factor to calculate the real power. Ideally, both have zero phase difference, but in practice, they have very minimum phase difference and sometimes depends on the connected loadseither resistive or inductive or capacitive. So, by taking samples within a little period, the total power of a cycle is measured then power is calculated and after all to gain total power average of the complete cycle is undertaken.

Taken Steps in Power Calculation:

1. Taking samples of 60 ms
2. Averaging V_{rms}values and power factor
3. Running these two things for 1 second
4. Averaging I_{rms}values and power factor
5. Calculating power, P= (V_{rms} × I_{rms}× power factor) W
6. Getting energy for this 1 second, E= [{ (P × 1) ÷ 1000 } ÷ 3600]KWh

To measure the total used unit, we will be adding this energy at every second and then we can find out the cost just by multiplying the per unit cost with it. In case of this project simplest power calculation formula has been taken in hand. Power factor has been considered as unity or 1. Only the voltage and current has been considered for the calculation.

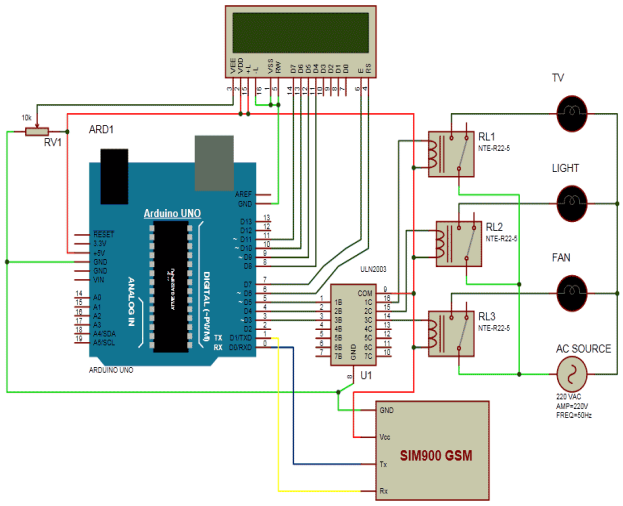

Fig. 2. The proposed system

After successfully determining the total used unit, the system is trained a few days to manipulate the threshold level of the integrated area. The average value of the few days observation is considered as a threshold value. Next time if the system finds out that the total used unit exceeds the threshold level then it notifies the authority through SMS service to take necessary steps. Afterward, the authority makes sure either anyone is working in this area or not. If any response doesn't found from that area, then the authority will send a command to the system through SMS to turn off the load. In case of any response, the authority will decide either he turns off the load or not.

The proposed system is classified into the following parts:

A. *Circuit operation*

The whole system is developed by following the circuit design shown in figure 2. The RX and TX pin of the GSM module relates to the RC6 and RC7 pin of the PIC16F876A respectively while pin 21 to 28 of the PIC16F876A except pin 24 relates to16X2 LCD display. Other loads are attached according to the circuit diagram.

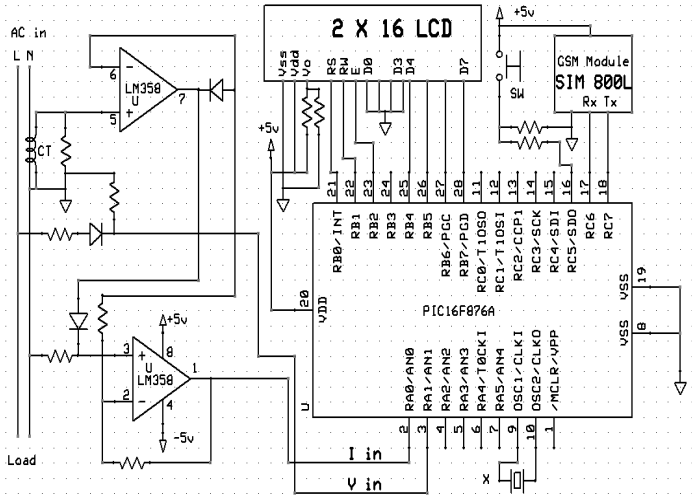

Fig. 3. Circuit design of the proposed framework

B. *Hardware:* Following pieces of equipment are utilized to develop the hardware part.

1)	MCU	PIC16F876A
2)	LCD	2X16 LCD 2 nos
3)	GSM Module	SIM800L/SIM900A
4)	Crystal oscillator	16MHz
5)	Current transformer	50A
6)	Op-Amp	LM358
7)	Diode	IN4007
8)	IC base	28 pin
9)	Resistor	
10)	Capacitor	
11)	Touch switch	
12)	Vero board	
13)	Arduino	UNO/Mega
14)	Relay	One/Two Channel
15)	Bread Board	
16)	Connecting Wires	
17)	Power Supply	

C. *Softwares:*

Arduino IDE and language is used to write the code and burnt into the system that is easy to understand and reliable.

D. *Algorithm:*

At first, the system gets power from the AC power source which can be used from the load or from any other source and Preparation of the system is an event that is taking place after providing the power. In this process, it's read the PIC memory. Then it measures the voltage and current in real time. Voltage can be taken easily for the calculation in the peripheral interface controller. But for taking the current measurement, a peak detector circuit has been used to get the current data easily. A diode has been used to make the alternating current or AC to DC value. After converting the voltage value to DC, the information goes to the PIC for easy calculation. Providing the voltage and current information we get the power and watt-hour using the equation. While calculating the watt-hour, the PIC updates the present current reading and updates the current memory and count day. After taking the average of the few days readings, the system sets a threshold value. From the next day, if the system observes any time the exceeding of the threshold level, it informs the authority through delivering SMS by SIM800L GSM module. If the power consumption does not exceed the threshold level, the system continues to monitor the area. The whole system relates to the relay. In reply to the notification of the exceeding threshold level, the authority confirms either anyone using the load of that area or not. Based upon the confirmation the controller of the load

sends a specific code through SMS. The GSM module converts the code into a signal which proceeds by Arduino. The Arduino sends a signal to the relay to turn off the load and LCD monitor show the Status.

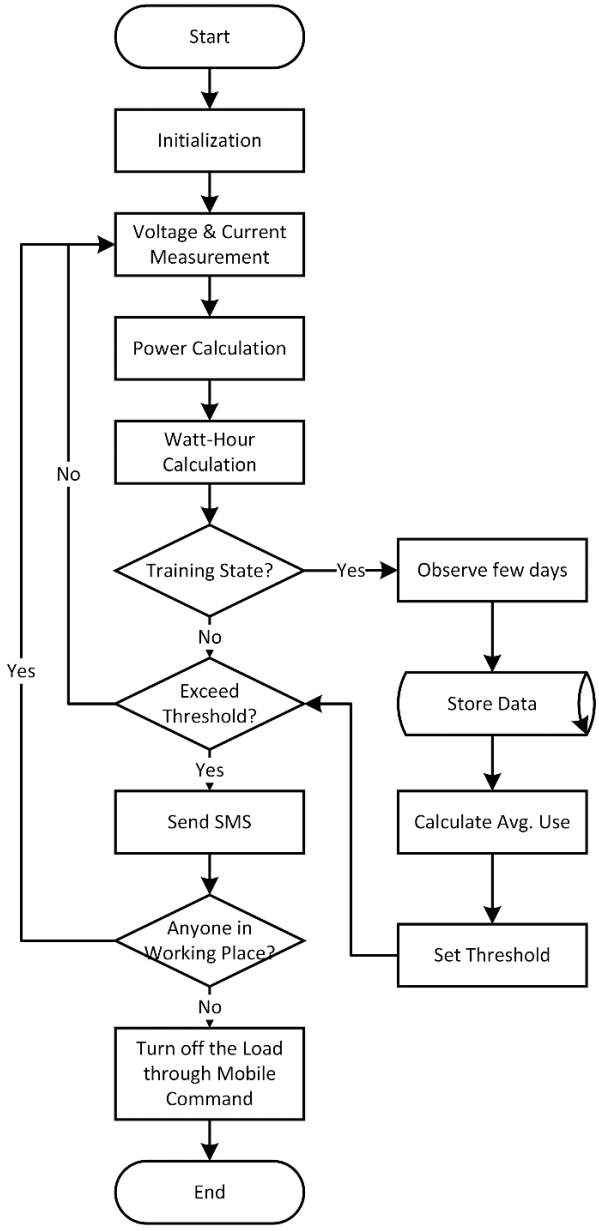

Fig. 4. Smart meter working process

IV. Experimental Results and Discussion

A prototype of the proposed system appears in figure 4 and5 where figure 4 demonstrates the monitoring unit of the system and figure 5 illustrates the controlling unit of the system. In the process of gathering data from actual sewing floor, the developed smart energy monitoring device has been integrated successfully. The data is deduced from office, air condition, light and fan connection. Light and fan connections of the sewing floors are considered for the experiment purpose. This data has been taken for a week. While taking the data, we have checked the amperage rating with an actual amperage meter for any inconsistency. After checking it, we found that it is almost the same.

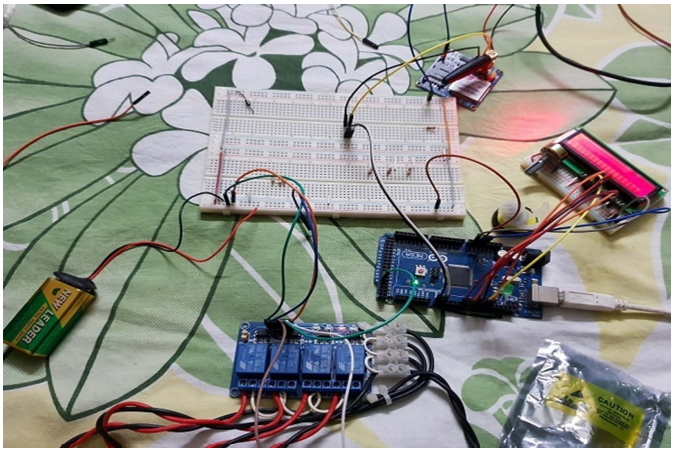

Fig. 5. Monitoring Unit of the system

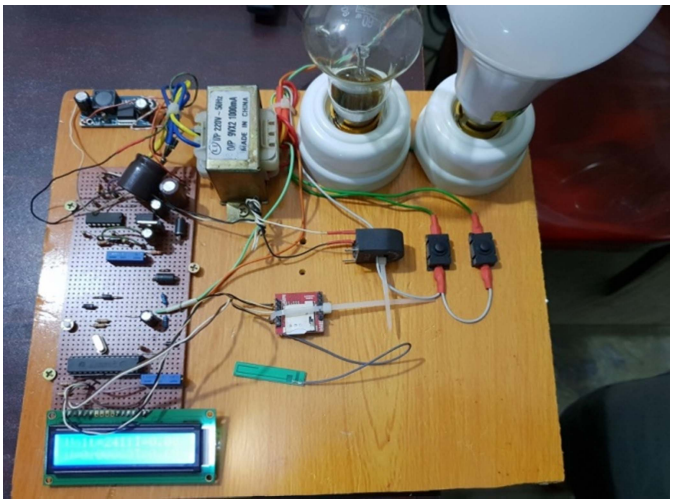

Fig. 6. Controlling Unit of the system

The figure 6 shows a typical sewing floor layout of a garment industry where there have almost 16 lines. From this line, the system works in the red marked lines. Among various loads of a garment industry the lights, fans and air condition of sewing floors are considered.

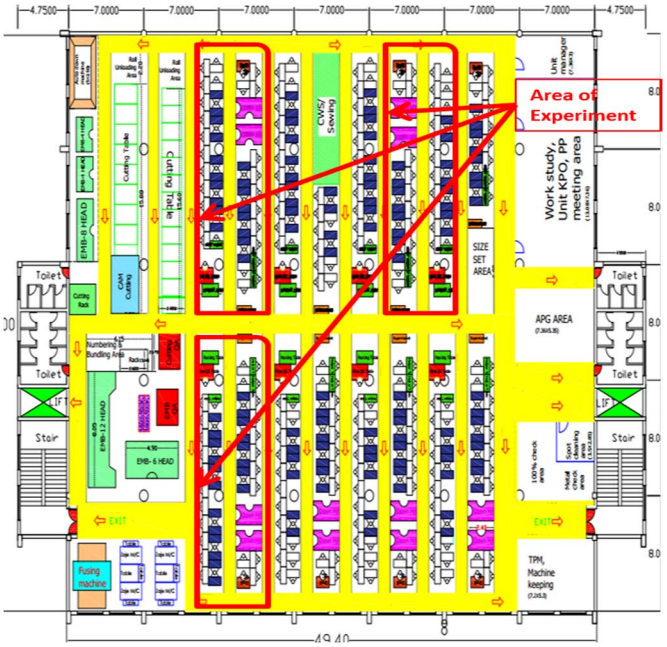

Fig. 7. Typical Sewing Line Layoutof YOUNGONE(CEPZ) Ltd.

Estimated actual data of per day electricity consumptionfor different loads appear in table 2. The sewing floor runs up to 9 hours per day in a regular working hour while 11 hours in case of overtime. During usual working hour all the machines are in operation, but in overtime some machines are inactive. Here considering 11 hours overtime load for sewing is 20.02 kW and by using IOT based smart energy meter, we calculated the same overtime hour load 18.3 kW which gives us 9% saving of energy. In the same way, we can get 10% savings from conventional light and 12% savings from the LED. Also in the case of fans(Korean and Bangla) and AC, we found consequently 7%, 10% and 11% of energy savings.

TABLE II. PER DAY CONSUMPTION OF DIFFERENT LOAD

Area	Light Consumption In total (Per Day)								
	Total Sheds	Watt	Total kW	Usage Calculated for 9 Hours	Cost in tk (per unit 8.99 taka as per BEPZA)	Usage Calculated for 11 Hours	Cost in tk (per unit 8.99 taka as per BEPZA)	After IOT Energy Meter	Percentage of Saving
Sewing	65	28	1.82	16.38	147.2562	20.02	179.9798	18.3	9%
Conventional	32	72	2.304	20.736	186.41664	25.344	227.84256	22.7	10%
LED	65	20	1.3	11.7	105.183	14.3	128.557	12.6	12%
Area	Fan Consumption In Total (Per Day)								
	Total Quantity	Watt	Total kW	Usage Calculated for 9 Hours	Cost in tk (per unit 8.99 taka as per BEPZA)	Usage Calculated for 11 Hours	Cost in tk (per unit 8.99 taka as per BEPZA)	After IOT Energy Meter	Percentage of Saving
Korean	12	40	0.48	4.32	38.8368	5.28	47.4672	4.887	7%
Bangladeshi	12	75	0.9	8.1	72.819	9.9	89.001	8.923	10%
Area	Consumption In Total (Per Day)								
	Total Quantity	Watt	Total kW	Usage Calculated for 9 Hours	Cost in tk (per unit 8.99 taka as per BEPZA)	Usage Calculated for 11 Hours	Cost in tk (per unit 8.99 taka as per BEPZA)	After IOT Energy Meter	Percentage of Saving
AC Ofiice	1 (2ton)	2100	2.1	11.34	101.9466	23.1	207.669	20.445	11%

A comparison in terms of cost between an existing energy meter and our IoT based smart meter for regular light power consumption is shown in table 3. The same information is displayed for LED light, Korean Fan /Bangladeshi Fan intable 4 and 5.A weekly consumption scenario is given in these tables

TABLE III. LIGHT CONSUMPTION IN SEWING FLOOR WEEKLY

Item / Day		1st October 2018	2nd October 2018	3rd October 2018	4th October 2018	6th October 2018	7th October 2018	8th October 2018	Total
IOT	Light	18.056	18.157	18.014	18.856	17.67	18.689	18.782	128.224
Regular		20.178	20.457	20.746	20.111	19.054	20.258	20.347	141.151

TABLE IV. LED LIGHT CONSUMPTION IN SEWING FLOOR WEEKLY

Item / Day		15th September 2018	16th September 2018	17th September 2018	18th September 2018	19th September 2018	20th September 2018	22nd September 2018	Total
IOT	LED Light	12.45	12.137	12.87	12.42	11.804	12.06	12.49	86.231
Regular		14.45	14.85	14.12	14.65	14.68	14.99	14.55	102.29

TABLE V. FAN CONSUMPTION IN SEWING FLOOR WEEKLY

Item / Day		6th September 2018	8th September 2018	9th September 2018	10th September 2018	11th September 2018	12th September 2018	13th September 2018	Total
IOT	Korean Fan	4.882	4.47	4.25	4.31	4.21	4.95	4.87	31.942
Regular		5.28	5.45	5.17	5.46	5.49	6.2	5.78	38.83
Item / Day		29th August 2018	30th August 2018	1st September 2018	2nd September 2018	3rd September 2018	4th September 2018	5th September 2018	Total
IOT	Bangladeshi Fan	8.45	8.41	8.21	8.16	8.78	8.78	8.46	59.25
Regular		9.92	9.78	9.8	9.78	9.65	10.23	9.94	69.1

In the training phase, the average value of a few days' usages is set as a threshold limit. In the second phase, the system will inform the user by delivering an SMS about the current reading in case of crossing the limit. Figure 7 shows a saving scenario by using our proposed smart meter where the red line demonstrates the consumption through normal energy meter, and the blue line demonstrates the consumption through the GSM-based smart energy meter. From the figure, it's recognized that a significant reduction in energy usage is achieved after the use of the smart energy Meter.

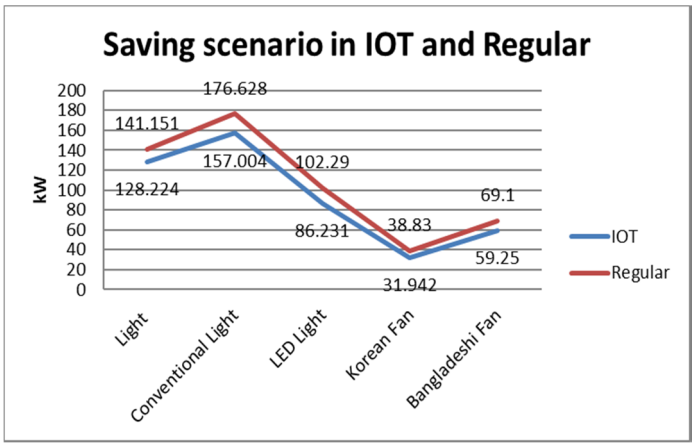

Fig. 8. The saving scenario in the consumption places weekly basis

In table 6 all the electrical loads' savings has been shown in a chart for ease of understanding.

TABLE VI. PER DAY CONSUMPTION OF DIFFERENT LOAD

Consumption From	Total kW	Cost In tk (per unit 8.99 taka as per BEPZA)	After using IoT based Smart Energy Monitoring Total kW	Percentage of savings %
Light (65 sheds)	141.151	1268.94	128.224	9.05%
Conventional Light	176.628	1587.88	157.004	11.11%
LED Light	102.39	919.5871	86.231	15.78%
Korean Fan	38.83	349.0817	31.942	17.73%
National Fan	69.1	621.209	59.25	14.254%

V. CONCLUSION

Notifying and controlling the idle usage of the machine of the garment industry could save a vast amount of power wastage. This study proposes a smart energy meter where the authority is notified about the excessive usage and idle usage of the loads through SMS service and can control the load remotely. Smart controlling of the electrical load can be achieved by sending a simple message to the designated number of the GSM module. Anyone knowing the designated SIM number can operate the load from sitting far away through a specified command. The proposed system is more cost-efficient and smarter than existing energy meter. Tampering the connection of existing meter did not make any good result to read data in the first training step of the proposed meter. It needs to make a separate circuit to measure energy consumption. Smart energy meter can be modified for the detection of illegal use of electricity. In the prototype of the proposed system, at present light, LED light, fan of the sewing floor is considered, and data manually collected from the experimental YOUNGONE(CEPZ) Ltd. area. Controlling the wastage of the heavy weighted machine and developing a data acquisition model to collect the energy consumption data from the loads existing on a single section of a single industry and transmit the data to a centralized server for further processing and analysis is a future scope of our proposed work. Also, other means of communication could be used instead of GSM networks. The authority of the garment industry of Bangladesh should integrate our efficient and effective energy meter to defeat the power wastage problem.

***Abstract*—Now-a-days the use of social media (e.g; facebook, twitter etc.) is increased rapidly. It is rational to exploit interest of users based on their facebook-page activities. However, it cannot be easily predicted manually as there are number of attributes including social interactions. The aim of this paper is to do analysis of 7 data mining algorithms and their variants for determining the best appropriate prediction of people interest in facebook pages. For this, we will analyze and compare various algorithms such as KStar, LWL, IBK, J48, Naive Bayes, Bayes Net, Decision Table. Their performances have been evaluated by using a dataset with 10172 instances of 6 attributes each. Among all the utilized algorithms Bayes Net demonstrates the best execution in regard to the accuracy. However, in respect to the computational time KStar demonstrates the best execution instead of Bayes Net.**

Keywords - data mining, facebook pages, prediction, performance, weka

I. Introduction

Social media turns out to be increasingly more well known in recent days. Individuals utilize online life for various purposes. In web based life, individuals can visit diverse sorts of online business destinations. By these locales advertisers can speak with their clients. Client can put request, think about the items, think about the refreshed market cost of various items and do a lot more things from anyplace at whenever. Web based life is a standout amongst the most critical apparatus to recover information of client enthusiasm for web based business destinations.

Recognizing individuals interest is imperative points for online trade. There exists distinctive sorts of mining algorithms for recognizing the clients and their interests. Clients are verified by various sorts of procedures, for example, PIN, password, user name, email, identification cards and so forth.

Social Networking sites are the massive source for big data that gives the opportunity to study about the human behaviors and interactions in different perspectives. Numerous analysts do their exploration to distinguish the client through the online networking communications. Facebook is a stage that empowers clients to speak with different clients through Internet associations. As indicated by a report of Statistica [1] practically 1.79 billion dynamic clients are utilizing facebook. Consistently 16 percent clients are expanding. Every day 1.18 billion individuals do login to facebook. Research demonstrates that billions of clients every day impart to one another through facebook.

In facebook, clients can communicate by means of post or status, comment, reply, chat and so forth. Individuals additionally speak with one another by means of video call. There is an alternative to respond (e.g, happy, wow, angry etc.) to a post. Clients can make remark and reply to a post. The posts involve with writings as well as suit pictures, or different connections like URLs. To recognize the notoriety of various online business pages of facebook, the posts of the distinctive pages are partitioned into two classifications: textual and interactive. The texual part contains the content, hashtag or URLs of the post and the interactive part contains the like, remark and answer of the specific post. Textual status can be posted in users timeline and the interactive posts can be shared by other users [3, 4]. Users can follow any posts of any page or any user. Clients can follow any posts of any page or any client. To post the status client can utilize hashtag to characterize a specific points [5]. In this paper, we exhibit an instrument to discover the prominence of the facebook pages through data mining algorithms.

The rest of the paper is organized as follows. The following section demonstrates the background study. Section 3 describes the methodology of this paper. In Section 4, experimental results are discussed. The paper is concluded along with the direction of future works in Section 5.

II. Background Study

Identification of people interest is very important, as it finds diverse applications. Many researchers work on finding the human interest in diverse social media [6–8]. Sleeper [9] tried to find out the people interest from facebook posts and likes. There exists some researches to identity the users mentality for business purpose [10]. Through social media usually many things are happening such as message spreading, voting, relationship, personalized advertising [11].

Foster [12] have been studied about to find out the stress, closeness from online interactions. A novel relationship between personal advertising and posts from facebook is presented by Kruike et al. [13]. Scissor [14] extracted the attitudes and behaviors from facebook like's option. Another study [15]

demonstrates the learning interest and satisfaction in social media. Human activities in social media should have some patterns for being used in identifying the user sentiments. This has prompted us to study the users interactions in facebook pages to explore human interests. Many data mining algorithms are available to identify or classify data for finding the patterns. Hence, we took 7 algorithms to classify information of different facebook pages to categorize them. This research gives us the opportunity to figure out the better algorithm for extracting the people's interest from online interactions.

In this study, 7 unique kinds of data mining strategies are examined. The strategies are KStar, Decision Table, J48, Naive Bayes, Bayes Net, IBK, LWL. Scientists work with these data mining systems for various issues [16, 17]. A case based languid learning classifier, KStar [18], stores the preparation information and after that performs handling to discover the test information. KStar utilizes entropy based separation which varies it from the other occurrence based learners [19]. It is like the K-Nearest-Neighbor classifier [20].

IBK is a k-closest neighbor classifier. In this calculation an item is characterized by a greater part vote of its closest neighbors [21]. Boyer-Moore lion's majority vote calculation is utilized to discover most of a grouping of components linear time in constant space. Vote is a prototypical case of a streaming algorithm [22].

Decision Table [23] is appropriate for test knowledge exploration. The tree structure relies upon the information which performs forecast. In this model, result esteems are spoken to with leaves and characteristics of datasets are known as branches. Decision Tree does not settle on any choice in data mining instead of it helps for settling on choice. There exists varieties in Decision Tree, for example, CART, CHAID, J48, ID3, C4.5 and so forth. In our research, J48 calculation is utilized. J48 enables client to anticipate the target variable of another dataset record [24, 25].

Naive Bayesian classifier utilizes the Bayes restrictive likelihood rule for performing order, expecting traits are measurably autonomous. The word Naive methods qualities of the informational index are considered as autonomous [26].

Bayes Nets or Bayesian systems [27] are graphical portrayal of probabilistic connections. It makes relations among a lot of self-assertive factors. A Bayesian system is deciphered with Directed Acyclic Graph (DAG) that encodes a joint likelihood dissemination [28]. It utilizes the likelihood capacity to anticipate distinctive data.

III. Proposed Methodology

In this paper, user interest in online social media is identified via user interactions on facebook page. Our proposed methodology involves the following steps.

1) Acquire posts from selected facebook pages.
2) Extract interactive data such as likes, comments, replies, posts name, and URLs (page names), texts from posts.
3) Analyze acquired data to explore human behavioral interest.
4) Apply matching techniques on training and test data set for identifying the people interests.

We have conducted experiment with the collected dataset for different data-mining techniques. The experiment is performed on the basis of test mode of k-fold cross-validation with supplied test sets (where k=10). For the performance analysis, some performance factors are focused like predictive accuracy and model building time, true positive (TP) rate, false positive (FP) rate, F-measure, etc. The flow chart of this presented study is given in Fig. 1.

A. Data Acquisition

We manually collected 10172 posts from 20 facebook pages over a period of more than three months. Initially, 50 active pages, where both Bengali and English languages are used, from facebook are selected on a random basis. Among them, the most prolific 20 pages are identified who produces more than 20 posts per week. All the data are collected manually and no tools are used to collect the data. Some sample data are presented in Table I. We have divided our data (posts) into five sessions. Each record (post) comprises of total 6 attributes: likes, comments, replies, post title, page likes and page name along with texts. Collected data set are available in our dropbox link [2]. The attributes are collected on the basis of the user input. Mainly 6 attributes are more effective for showing peoples interest and interaction in facebook pages. By analysing those attributes the popular or more interactive post can be identified easily. The collected attributes help to identify the user interest by classifying inputed data.

We extracted the top 50 interests (e.g; Interior decorating, Painting, Shopping, Cooking, Leather, Devices, Gaming, Cricket, Football, Travelling etc.) based on occurrence in the facebook pages from 10172 random posts. We shorten the list of interests by excluding any interest that occurred within multiple post in different facebook pages. By using different types algorithm we can identify people interest. All the analysis of predicting user interest are shown in result section.

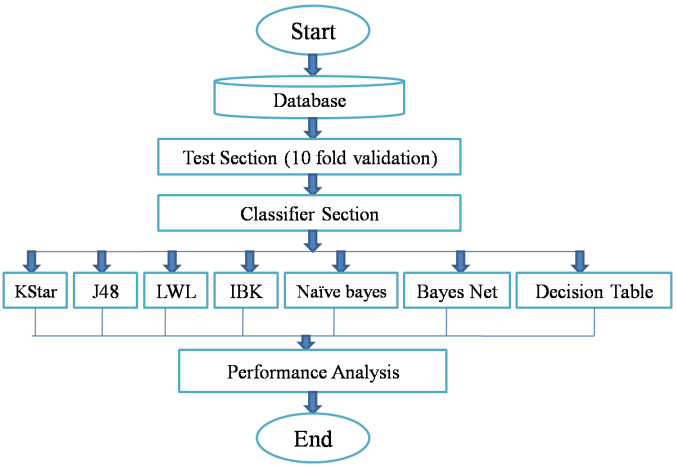

Fig. 1. Data mining classification process

B. Preparing dataset

We converted the dataset from CSV (Comma Separated Value) format to ARFF (Attribute Relation File Format) which can be easily uploaded in Weka software [29].

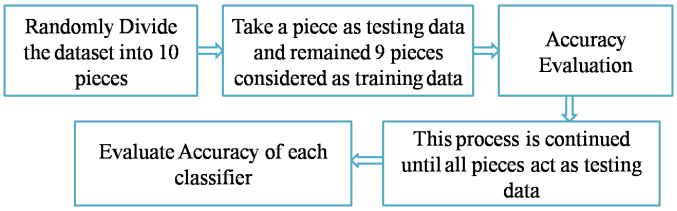

Fig. 2. 10 cross-validation process for our experiment

C. Experiment using Weka software

We investigated each mining algorithm for the prepared dataset. The investigation process is shown in Fig. 1. Cross-validation divide a dataset into 10 pieces (folds). Moreover, hold out each piece in turn as testing and train on the remaining 9 pieces together. This gives 10 evaluation results, which are averaged. By doing 10-fold cross-validation and then computed the evaluation results, Weka invokes the learning algorithm 11th time on the entire dataset to obtain the model [30]. Fig.2 shows the graphical view of cross-validation process that has been used in the current experiment. In this study, different accuracies are found for different classifiers. All information about the classifictaion results of classifiers are collected from Weka software. Performance of all classifiers have been compared and shown in Table II.

IV. Results and Discussions

In this study, We ran 7 separate experiments to decide how well we can foresee individuals performance for various facebook pages utilizing diverse data mining procedure. We ran the majority of our experiments in weka utilizing 7 types classifiers (e.g; KStar, LWL, IBK, J48, Naive Bayes, Bayes Net and Decision Table) more than 5 times running of 10-overlay cross-approval.

Confusion matrix along with computation time gives the entire information about correctly and incorrectly classified instances for each classifier. Based on the data, we consider the following statistical measures such as TP rate, FP rate, Precision, Recall, F-Measure, Accuracy for comparative performance analysis of different data mining algorithms. These statistical measures are calculated through equation $1-6$. Equation 1 helps to find the accuarcy of the classifiers that used in this experiments.

$$Accuracy = \frac{\sum TruePositive + \sum TrueNegative}{\sum TotalInstances} \quad (1)$$

$$TruePositiveRate(TPR) = \frac{TP}{TP + FN} \quad (2)$$

$$FalsePositiveRate(FPR) = \frac{FP}{FP + TN} \quad (3)$$

$$Precision = \frac{TP}{TP + FP} \quad (4)$$

$$Recall = \frac{TP}{TP + FN} \quad (5)$$

$$FMeasure = \frac{precision.recall}{precision + recall} \quad (6)$$

Where, TP, FP, TN, FN denotes True Positive, False Positive, True Negative, False Negative respectively.

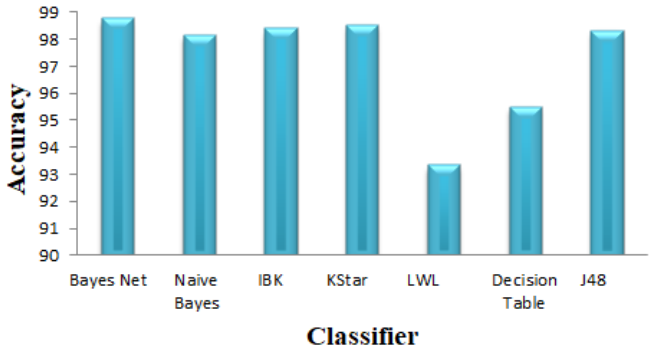

Fig. 3. Accuracy of classifiers

As accuracy is an essential execution parameter, so we exhibited the accuracy of all classifiers graphically in Fig. 3. KStar, IBK, J48, Naive Bayes, Bayes Net perform superior to different classifiers. Table II demonstrates the point by point accuarcy, TP rate (TPR), FP rate (FPR), Precision, F-Measure. TPR, FPR is calculated through equation 2 and equation 3. Moreover, Presicion, F-Measure and Recall are derived from equation 4, equation 5 and equation 6. From Table II we locate that the greater part of the utilized classifiers false positive rate is low and genuine positive rate is very significant. By consolidating the TPR, FPR, precision, recall, F-measure and accuracy, we find that bayes and tree learners give the preferred outcome over the others do. Bayes Net effectively grouped 10019 cases; be that as it may, it can't characterize 103 occurrences accurately. Naive Bayes classified correctly 9966 instances and incorrectly 206. Whereas, other used classifiers as IBK, Kstar, LWL J48 and Decision Tree correctly classified 9989, 10003, 9460, 9663, 9980 instances respectively. KStar gives the best performance other than 7 classifiers concerning computational time and accuarcy.

V. Conclusion and Future Work

The presented paper focuses to find the correct data mining calculation to predict the general population interest for various facebook pages as indicated by info properties. It cannot be effectively anticipated physically as it is troublesome assignment which requests higher learning and aptitude. In this paper, we have made a thorough relative investigation of 7 diverse order calculations, for example, KStar, LWL, IBK, J48, Naive Bayes, Bayes Net, Decision Table. Their results have been assessed through Weka programming by utilizing

gathered dataset containing 10172 records. In view of the execution factors KStar, Naive Bayes, Bayes Net, J48, IBK work practically comparable and give the preferable execution over other grouping techniques. KStar demonstrates the best execution over the 7 classifiers concerning computational time and accuarcy.

In future, we intend to research individuals' enthusiasm to look for progressively precise expectation and make a regressional investigation to proposed the connection between computational time and accuracy.
