## *ACKNOWLEDGEMENT*

All praises due to Almighty ALLAH 'who has enabled the author to complete this thesis successfully.

The author really does not have adequate words to express his heartfelt sense of gratification, ever indebtedness and sincere appreciation to his benevolent teacher and research supervisor, Professor Dr. Roushan Ara, Chairman, Department of Entomology, Hajee Mohammad Danesh Science and Technology University, Dinajpur for her constant help, scholastic guidance, valuable suggestions, timely and solitary instructive criticism for successful completion of the research work as well as preparation of this thesis. The author is highly pleased to express his gratitude to his co-supervisor Dr. Md. Adnan Al Bachchu, Associate Professor, Department of Entomology, HSTU, Dinajpur for his keen interest, valuable advice, creative suggestions, kind co-operation and encouragement from the beginning to the end of the study and corrections in writing this thesis.

The author is grateful to all teachers of the Department of Entomology, HSTU, Dinajpur for their encouragement during the period of study.

The author expresses his special thanks to Md. Hafizur Rahman Hafiz, Assistant Professor, Department of Corp Physiology and Ecology, HSTU, Dinajpur for his valuable suggestions and kind help for analyzing data and preparing this manuscript.

The author expresses many thanks to all the laboratory and official staffs of the Department of Entomology, HSTU, Dinajpur and special thanks to Md. Robiul Hasan for his skilled help during the study.

The author expresses his deepest sense of respect to his parents, brother mention the name sisters, relatives and all of his friends for

their blessings, inspiration, advice and moral supports in all phases of his studies.

Finally, the author expresses his immense indebtedness to his elder brother for his cordial help untiring co-operation and inspiration at all times during this study.

INSECTICIDAL PROPERTIES OF SOME PLANT EXTRACTS  
AGAINST LESSER GRAIN BORER, *RHYZOPERTHA*  
*DOMINICA* (F.)  
(BOSTRICHIDAE : COLEOPTERA)

ABSTRACT

The study was carried out in the laboratory of the Department of Entomology, Hajee Mohammad Danesh Science and Technology University, Dinajpur during the period from April to December 2012 to evaluate the efficacy of different plant extract viz. Ata (*Annona reticulata*), Karabi (*Nerium oleander*), Neem (*Azadirachta indica*), Biskatali (*Polygonum hydropiper*) and Akanda (*Calotropis gigantea*) in petroleum ether for the toxicity, residual and repellent effects against lesser grain borer, *Rhyzopertha dominica*. The leaf extracts of above mentioned plants were applied at three doses viz. 4.0, 6.0 and 8.0% concentration. The result showed that extracts of five tested plants had toxic and repellent effects on lesser grain borer. Neem leaf extract showed the highest toxicity and repellent efficacy on lesser grain borer. Even though all the doses had toxicity, residual and repellency effects but the highest efficacy showed at 8% concentration ( 8% dose showed the highest response). On the basis of the LD<sub>50</sub> values, it was observed that the neem extract showed the highest performance. Considering all the concentrations, the order of toxicity levels of five plant extracts on

lesser grain borer was found as neem> biskatali> karabi> akanda > ata. Mortality percentages were directly proportional to the time after treatment. In case of repellency, it was found that all the tested extracts were in the same repellency class i.e. class II. As the progress of time mortality percentage increased (with the progress of time) meanwhile the repellency effect decreased.

## 1. INTRODUCTION

### 1.1 General Background

Losses due to insect infestation is one of the most serious problem in storage, particularly in villages and towns of developing countries like Bangladesh. Storage loss may also be significant in developing countries where more than 70% of cereal production is stored in farms (Kavita, 2004). It has been estimated that about 15-20% of the world agricultural production is lost every year due to insect infestation (Wright, 1985). In Bangladesh, the annual grain losses cost over taka 100 cores (Alam, 1971) whereas in India losses caused by insects accounted for 6.5% of stored grain (Kumar, 2009). The climate and storage conditions, especially in the tropics, are often highly favorable for insect growth and development (Jacobson, 2004).

Stored food grain of Bangladesh suffers seriously from the attack of a number of insect pests. Insect pests become important in stored grains soon after man first learned to keep grain for seed and other purposes. Their attacks reduce both the quantity and quality of stored seed (Salim, 1978). The stored product insects not only feed on the stored food but also cause organoleptic change in food grains as a result of which the nutritional value of the food grains is reduced. In addition, they also cause fermentation and acidification of food grains and many other changes. Sometimes moulds grow in the insect infested food grain and these moulds produce a chemical substance called aflatoxin which is reported to be associated with the liver cancer of human being (Singh,

1983). Stored grain at high temperature and relative humidity provides an ideal condition for a rapid buildup of the population of many stored insects (Wallbank and Greening, 1976) and the grains become unfit for human consumption and sowing in the field (Husain and Roy, 1997).

Insects belonging to different families have been identified from stored product in various part of the world (Hinton, 1945). About 600 species of insects have been identified from stored products in various parts of the world (Imamura, 2004). Among these species lesser grain borer, *Rhyzopertha dominica* (Coleoptera: Bostrichidae) is common and most destructive pest. This insect is originally an inhabitant of India (Atwal, 1976). Now it occurs all over the world and specially encountered in warm situation in temperate zones. Both the adults and grubs cause serious damage to stored grains and stored products such as rice, wheat, sorghum, barley, lentil, corn flour, beans, millets etc. They feed inside the grains and cause damage reducing them to more shells, having many irregular holes. In severe infestation, the damage is very high where a considerable amount of loss is caused by spoiling more than what they eat.

A good number of devices and principles and practices have been reported for the management of grain borer and other stored grain pests (Das *et al.* 1999). Many investigators suggested chemical insecticides for their control. Chemical control of insects in storage has been used with serious drawbacks (Sharaby, 1988). Indiscriminate use of chemical pesticides has given rise too many serious problems, including genetic

resistance of pest species, toxic residues, increasing costs of application, environmental pollution, hazards from handling etc. (Ahmed *et al.*, 1981; Khanam *et al.*, 1990). Developing of cross and multiple resistant strains in many important insect species resulting from the continuous use of chemical insecticides has been reported from all over the world (Dyde, 1970; Pasalu and Bhatia, 1983; Zettler and Cuperus, 1990; Zettler, 1991). Fumigation of stored food grains with toxic gases is effective but not applicable at the farm level because the storage structures are not airtight. This situation indicates the need for safe but effective, biodegradable pesticides with no toxic effects on non-target organisms, locally available and less expensive materials for pest control in storage. This has created a worldwide interest in the development of alternative strategies, including the search for new types of insecticides and use of age-old traditional botanical agents (Heyde *et al.*, 1983). Locally available plant and plant materials have been widely used in past to protect stored produce against damage by insect infestation (Golob and Webley, 1980). Plants are nature's chemical factories, providing richest source of renewable bioactive organic chemicals. The effectiveness of many plant derivatives against stored product insect pests has already been demonstrated (Xie *et al.*, 1995). The total number of plant chemicals explored today exceeds 4,00,000. Of these only 10,000 have been established as secondary metabolites whose major role in plants has reportedly been defensive, specially against insect pests (Das *et al.*, 1999).

Botanical products are environmentally safe, less hazardous and less expensive. The main advantage of botanical insecticides is that they can be easily produced or collected by the farmers in the house and small-scale industries. However, a very few scientific research works has been done in Bangladesh to explore our locally available plant materials for the control of harmful insect pests in storage. These botanical materials can be used as an alternative to chemical pesticides. This will be very helpful in minimizing the undesirable side effects of synthetic pesticides.

## 1.2 Research Objectives

The present study was carried out with five locally grown plants namely neem, biskatali, ata, karabi, and akanda to investigate their compatibility in the IPM programme by determining their toxicity, repellency and residual effects against a major stored product insect, namely lesser grain borer, *R. dominica*. Therefore the specific objectives of the present research work are as follows:

1. To determine the direct toxic effect of plant extracts against lesser grain borer.
2. To evaluate the repellent properties of test plant extracts under simple laboratory technique.
3. To determine the residual effect of five test plant extracts against *R. dominica*.

## 2. REVIEW OF LITERATURE

Stored grain suffers seriously from the attack of a number of insect pests. Control of insect pest by botanicals has drawn special attention all over the world. The use of botanical as stored grain protected is known since long. There were many reports published on the use of plant materials against stored pests but the information against lesser grain borer *R. dominica* Herbs. are scanty. Relevant information of the research works

in home and aboard on stored product insect pests management by botanical insecticides has been reviewed below.

## 2.1 Toxic effects

Jagadiswari, R. and Anand, P. (1999) studied the insecticidal potentialities of goat weed on rice grain protectant against storage insects. The leaf powder of goat weed controlled the multiplication of *R. dominica* up to 6 months at the rate of 1 and 2 % and showed no grain damage on rice

Tripathi *et al.* (2005) studied on bioactivities of l-carvone, d-carvone, and dihydrocarvone toward three stored product insects. It observed that *R. dominica* adults were more susceptible than the other species to fumigant vapours of l-carvone, d-carvone, and dihydrocarvone. The comparison of contact and fumigant toxicity of the test compounds indicates that l-carvone and d-carvone possess 24 times more fumigant toxicity toward *R. dominica* adults than its contact toxicity. The order of toxicity was l-carvone > d-carvone > dihydrocarvone.

Roy *et al.* (2005) studied on leaf extracts of shiyalmutra as botanical insecticides against lesser grain borer and rice weevil. The average mortality percentage showed that the extract at 3% was also the most toxic to both species (57.41 and 56.71% mortality in lesser grain borer and rice weevil, respectively). The percentage of insect mortality increased with the increase in the time interval after treatment.

Salema *et al.* (2007) studied on entomocidal effect of *Brassica napus* extracts on two store pests, *Sitophilus oryzae* (L.) and *Rhyzopertha dominica* (Fab.) They conducted that surface treatment of wheat seeds

with acetone or petroleum ether extracts of *B. napus* showed various toxicities to *R. dominica* adults, acetone extract was found to be the highest effective extract as it resulted 92.4% mortality at 4.0% conc. level, followed by diethyl ether extract (90%).

Djelatnost and Borah (2009) conducted an experiment on food production, enhanced pest resistance, as well as environment pollution exact researching for new reduced risk insecticides in stored pest's control. They showed that the application of botanical pesticides azadiractin, a seed isolate from the plant *Azadirachta indica* are highly toxic for lesser grain borer.

Kavallieratos *et al* (2009) studied the pyrole chlorfenapyr as a potential grain protectant against adults of *R. dominica*. They showed that mortality was low at 0.1 and 1 ppm for paddy rice but reached 74.4% in barley after 14 days of exposure and adult emergence for *S. oryzae* or *R. dominica*, was higher in paddy rice than in the other three commodities.

Kathirvelu *et al.* (2009) studied on botanical control of pongam and neem against lesser grain borer in stored paddy. The results revealed that mixing neem oil at 30 ml per kg of grains was effective against the pest, with 57.95% mortality of the borer, followed by neem leaf dust at 30% (50.90% borer mortality) and pongam oil at 30 ml per kg of grains (46.74% borer mortality).

Li-GuanHua and Batra (2011) tested to insecticidal activities of the essential oils from *Tephrosia purpurea* leaves, *T. purpurea* barks and *T. purpurea* seeds against *R. dominica* for toxicity test. The results showed

all the three kinds of essential oils had exhibited contact toxicity against the 5-day old nymph of *R. dominica*.

Rani and Datta (2011) assessed the leaf extracts of *Cocos nucifera* L. and *Terminalia catappa* L. as potential grain protectants against four major pests of stored grains, *Sitophilus oryzae* (L.), *R. dominica* (F.), *Tribolium castaneum* (Herbst), and *Callosobruchus chinensis* (L.). Results showed that adults of *R. dominica* showed tolerance to all the extracts tested in both fumigation and contact mode bioassays.

## 2.2 Repellent effects

Bailey and Bailey (1976) studied on effectiveness of spinosad against major stored-grain insects on corn. Insect species tested were the red flour beetle, lesser grain borer, rice weevil and maize weevil. Corn kernels were treated with spinosad at 0, 0.1, 0.5, 1, and 2 mg/kg for controlling the above insect species. Their results indicated that spinosad at the rate of 1 mg/kg was effective against the above stored-grain insect pests on corn.

Stemley and Wilbur (1996) conducted an experiment on susceptibility of maize grains to storage insects. Grains of seven elite maize genotypes were evaluated for their comparative resistance to lesser grain borer on free choice basis under laboratory conditions. The results indicated that adult progeny of both species and weight loss of grains were significantly low. The results suggested that resistant varieties could be incorporated in maize breeding.

Jagadiswari and Anand (1999) tested 20 new botanicals doses (11 oils and 9 leaf powder formulations) for their efficacy as paddy grain

protectants against *R. dominica*. The botanicals were applied as repellent treatment under controlled conditions of infestation on rice. Among the oils, cotton-seed and eucalyptus oils indicated absolutely highest repellent effect (75.6%) of the pest after 5 hours treatment.

Jagadiswari-Rao and Ezhilkumar (2001) studied on prophylactic treatment against lesser grain borer, *Rhyzopertha dominica* Fab. Result indicated that 0.5 and 1.0% doses showed maximum repellency (80.2%).

Tripathi *et al.* (2003) studied of l-carvone, d-carvone, and dihydrocarvone toward three stored product insects. After treatment to l-carvone, d-carvone, and dihydrocarvone on lesser grain borer they observed that l-carvone showed highest repellent effect after 4 hours treatment. The order of repellent effect was l-carvone > d-carvone > dihydrocarvone.

Sikha (2003) presented an extensive survey conducted to record the indigenous technological knowledge of rice crop in Assam, India, during 2002-03. Farmers have been using neem, Siam weed and chick weed in stores as well as in standing crops to prevent insect infestation since long back. Sweet flag *Acorus calamus*, Sanhund, Lantana, Sukhadarshan and Aloe are also grown along with rice as these indigenous plants are repellent to some insect pests.

Roy *et al.* (2005) conducted an experiment on the leaf extracts of shiyalmutra as botanical insecticides against lesser grain borer and rice weevil. The repellent activity increased with the increase of extract concentration. The extract of 3% concentration resulted highest repellency against lesser grain borer (55.71%).

Borah *et al.* (2005) studied on insecticidal activity of the petroleum ether extract of *Annona reticulata* Linn. leaves were evaluated against lesser grain borer (*R. dominica*) and rice weevil (*Sitophilus oryzae*). The repellent activity of the extract (.5, 1 and 1.5%) increased with the increase in extract concentration. The extract at 1.5% resulted in the greatest repellency against lesser grain borer (63.33%).

Kholy *et al.* (2007) showed that the tested *Brassica napus* extracts at different concentrations exhibited different repellency on adults of *R. dominica*. Chloroform extract was found to be the highest repellent agent (78.3%) repellency on the 2nd day against adults of *R. dominica*.

Kys (2007) studied on the influence of the herbs sage and wormwood on the migration of *R. dominica* (F.) populations. Under conditions permitting the migration of adult *R. dominica*, the addition of powdered sage to wheat grain resulted in a lower colonization of this substrate. It was also found that emigration from grain containing sage was very high, especially in the initial period of grain infestation. This leads to the conclusion that sage is a strong repellent effect.

Salema *et al.* (2007) tested the repellency effect on *Brassica napus* in laboratory against adults of *Sitophilus oryzae* and *R. dominica* at different concentrations. The obtained data showed that 4.0% conc. level of chloroform extract was found to be the highest repellent (78.3%) effect on the 2nd day against adults of *R. dominica*.

Li *et al.* (2009) studied on toxic action of essential oils from *Tephrosia purpurea* on *Rhyzopertha dominica*. They showed that repellent rate

reached to the maximum value (94.3%) after 48 hour treatment against adults of *R. dominica*.

Kumar (2009) studied on the effect of pea on repellent nature against stored product insects. Rice grains treated with protein-rich fractions obtained from wrinkled-seeded pea cultivars and a smooth-seeded pea cultivar at 1.0% concentration was effective in repelling the red flour beetle, rice weevil and lesser grain borer from treated grains compared to other treatment. Bonneville was highly effective in its repellent action against *T. castaneum*, *S. oryzae* and *R. dominica*.

### 2.3 Residual effects

Pasalu and Bhatia (1983) evaluated the toxic effects of *Brassica napus* against adults of *Sitophilus oryzae* and *R. dominica* at different concentrations. All tested extracts of *B. napus* showed various toxicities to *R. dominica* adults, acetone extract was found to be the highest effective extract as it gave 92.4% mortality at 4.0% conc. level, followed by diethyl ether extract (90%) after 7 days of treatment.

Wright (1985) studied the leaf powder of goat weed to control the multiplication of *R. dominica* up to 6 months (dose 1.0 and 2.0% w/w) and showed no grain damage on rice. Grain damage caused by *R. dominica* was also nil at both the higher doses of 1.0 and 2.0% w/w but at lower doses this borer caused grain damage.

Saraby (1988) studied the leaf extract of *Calotropis gigantean* against adults of *R. dominica*. They showed that the mortality was low at 0.5 and 1 ppm for rice but 74.4% in barley after 14 days of exposure.

Zettler (1991) studied on insecticidal activity of the petroleum ether extract of *B. lacera* leaves against *R. dominica* and *Sitophilus oryzae*. The extract at 4% resulted in the greatest toxicity against lesser grain borer (60.33%) and rice weevil (58.58%).

Kys (2007) studied on toxic action of essential oils from *Nerium oleander* on *Rhyzopertha dominica*. The results showed that highest toxicity was found (94.3% mortality) after 14 days of treatment.

Athanassiou *et al* (2007) studied the plant extract of neem against adults of *R. dominica*. The doses rates were 50, 100 and 150 ppm and mortality was measured after 7 and 14 days of exposure, at three temperatures (20<sup>0</sup>, 25<sup>0</sup> and 30<sup>0</sup> C) and 65% R.H. All adults were dead after 14 days of exposure at 55% R.H. at 100 ppm.

Rajendran *et al* (2008) studied on plant essential oils and their constituents as fumigants against stored-product insects. Fumigant toxicity tests conducted with essential oils of plants and their components have largely focused on beetle pests such as *R. dominica*, and *Sitophilus oryzae*. Adults were generally susceptible whereas, eggs were either tolerant or highly susceptible depending on insect species and the type of essential oil or component.

Kathirvelu *et al.* (2009) studied to assess the effect of botanicals *Azadirachta indica* and *Pongamia glabra* on *R. dominica* in stored rice, using leaf dusts and oils at different concentrations. Adult mortality was recorded 7, 15 and 21 days after treatment. The results revealed that mixing neem oil at 30 ml per kg of grains was effective against the pest, recording 57.95% mortality of the borer, followed by neem leaf dust at

30% (50.90% mortality) and pongam oil at 30 ml per kg of grains (46.74% mortality).

## 2.4 Test Plant

The test plant materials of five indigenous plants were collected from around the HSTU campus, Dinajpur. The descriptions of the plants are given below.

### 2.4.1 Ata

Scientific name: *Annona reticulata* Linn.

Family: Annonaceac

#### Morphology

*A. reticulata* tree is erect, with a rounded or spreading crown and trunk 10 to 14 inch thick. Height ranges from 15 to 35 ft. Leaves are deciduous, alternate, oblong or narrow-lanceolate, 4 to 8 inch long, 3/4 to 2 inch wide, with conspicuous veins (Plate 1). Flowers, in drooping clusters, are fragrant, slender, with 3 outer fleshy, narrow petals 3/4 to 1 1/4 in long; light-green externally and pale-yellow with a dark-red or purple spot on the inside at the base. The compound fruit are heart-shaped, lopsided, or irregular; or nearly round, or oblate, with a deep or shallow depression at the base. Single, hard, dark-brown or black, glossy seed (Plate 1); oblong, smooth, less than 1/2 inch long (Hooker, 1980).

#### Origin and Distribution

The *A. reticulata* is believed to be a native of the West Indies but it was carried in early times through Central America to southern Mexico. It is

commonly grown in the Bahamas and occasionally in Bermuda and southern Florida (Athanasios and Korunic, 2007).

#### Toxicity and uses

The seeds are so hard that they may be swallowed whole with no ill effects but the kernels are very toxic. The seeds, leaves and young fruits have insecticidal value. The leaf juice kills lice Ref. The bark contains 0.12% anonaine Ref. Injection of an extract from the bark caused paralysis in a rear limb of an experimental toad. Sap from cut branches is acrid and irritant and can severely injure the eyes. The root bark has yielded 3 alkaloids: anonaine, liriodenine and reticuline (muricinine) (Hertlein *et al.*, 2011)

The leaves have been employed in tanning and they yield a blue or black dye. A fiber derived from the young twigs is superior to the bark fiber from *Annona reticulata*. Custard apple wood is yellow, rather soft, fibrous but durable, moderately close-grained, with a specific gravity of 0.65. It has been used to make yokes for oxen (Nathan *et al.*, 2007). Morphology of Karabi is too detailed but in case of Neem, Biskatali are not as Karabi, so try to describe the main & same characters of plants for 5 tested plants.

Plate 1. Twigs, fruits and seeds of *Annona reticulata*

#### 2.4.2 Karabi

Scientific name: *Nerium oleander* Linn.

Family : Apocynaceae

#### Morphology

Erect glabrous shrubs, leaves usually in whorls of three, narrow coriaceous; nerves slender, very close. Flowers are large, in terminal racemose cymes. Calyx 5-partite, glandular within, segments narrow. Corolla funnel shaped lobes overlapping to the right. Stamens inserted near the mouth of the tube, filaments short; anthers conniving around and adhering to the stigma, tipped with long hairy appendages, each cell produced downwards into a rigid spur-like appendage. Carpels 2, distinct, many ovuled; style filiform or dilated upwards; stigma with a reflected lobed membrane surmounted by 5 tubercles, tip sub-globose. Follicles cylindric, straight adpressed. Seeds oblong, villous; coma terminal, caducous; albumen fleshy, cotyledons flat (Kirtikar and Basu, 1980) (Plate 2).

## Distribution

Upper Gangetic Plain, Himalaya from Nepal westwards to Kashmir up to 6,500 ft., salt Range, Waziristan, Baluchistan, Central and South India. Extensively cultivated throughout the greater part of India as well China and Japan. (Yamasaki *et al.*, 2007).

## Toxicity and Uses

All parts of the *N. oleander* contain cardiac glycosides, including the roots and the smoke produced from burning, as heat does not inactivate the glucocides. The toxic components are the two cardiac glycosides, glucocides, nerrin and olenderin which can be isolated from all parts of the plant. *N. Oleander* poisons are cardiac and gastrointestinal in nature to insects (Yamasaki *et al.*, 2007). *N. oleandar* has been known to be poisonous. The leaves are highly toxic and root is a cardiac poison. The bark of the root and the sweet-smelling leaves of this shrub are considered by the vydians as powerful repellents.

Plate 2. Plant parts of *Nerium oleander*

### 2.4.3 Neem

Scientific name : *Azadirachta indica*.

Family : Meliaceae.

#### Morphology

Neem is a perennial tree, 15-20m in height with a straight trunk; leaves are simple, number of leaflets 9-15, opposite, sub-opposite or alternate, lanceolate, acuminate or subfalcate. Flowers are white, Fruit (Drupe) oblong. (Rice *et al.*, 2007) (Plate 3).

#### Distribution

A common tree of Bangladesh and throughout the greater part of India, planted in the hot climate (Hooker, 1978).

#### Toxicity and uses

Neem is famous for its medicinal properties. The major active constituent is azadirachtin, which is well known for its antifeedant, toxic and growth regulating effects on insects (Saxena *et al.*, 2004).

Neem oil are contained three bitter compounds i.e. nimbin, nimbinin and nimbidin. It has been an aged practice in rural areas of Bangladesh to mix dried Neem leaves with stored grain to control stored grain insects. A variety of preparations based on Neem extracts have been tested against stored product insects. Azadirachtin-rich commercial "Margosan-O" is already produced in developing countries for controlling pests. (Jacobson, 2004).

Plate 3. Twig of *Azadirachta indica*.

#### 2.4.4 Biskatali

Scientific name : *Polygonum hydropiper*

Family : Polygonaceae

#### Morphology

Annual herb, reproducing by seeds stems are jointed, somewhat flattened ascending or erect. Leaves are alternate, simple, with waxy margins, dark green to brown (Rahman *et al.*, 2006) (Plate 4).

#### Distribution

Damp soils, low meadows, pastures, cultivated ground, and waste places of Bangladesh, India, North America, Europe and many other countries of the world. (Rahman *et al.*, 2006)

#### Toxicity and uses

It is a medicinal plant and also used to control insect pests as repellence, antifeedant and toxic materials. In rural areas of Bangladesh farmers are used to mix dried biskatali with stored grain to control stored grain insects. The toxic components are the two potent cardiac glycosides and i.e. are highly toxic for any kind of insect (Rahman *et al.*, 2006).

Plate 4. Plant parts of *Polygonum hydropiper*

#### 2.4.5. Akanda

Scientific name : *Calotropis gigantea*

Family : Asclepiadaceae

#### Morphology

It is shrub or small tree to 4 m, exuding copious milky sap when cut or broken; leaves opposite, grey-green, large up to 15 cm long and 10 cm broad, with a pointed tip, two rounded basal lobes and no leaf stalk; flowers waxy white, 5 petals, purple-tipped inside and with a central purplish crown, carried in stalked clusters at the ends of the branches; fruit grey green, inflated, 8 to 12 cm long (Kleinschmidt and Johnson, 1977) (Plate 5).

#### Origin and Distribution

It is originated from Iran to China; India to Sri Lanka; Indo-China, Indonesia and Malaysia. The *C. gigantea*, is native to the Old World

tropics but has been widely naturalized throughout the New World tropics including the Caribbean and on the continent from Mexico to Brazil (Pedriniet *al.*, 2011).

#### Toxicity and uses

The worms in the intestines get killed (Bailey and Bailey, 1976).

Plant 5. Plant parts of *Calotropis gigantea*

#### 2.5 The Test Insect

The lesser grain borer, *Rhyzopertha dominica*, a major pest of stored products, was used in this study.

#### Systematic position

Phylum : Arthropoda

Class : Insecta

Subclass : Pterygota

Division : Endopterygota

Order : Coleoptera

Family : Bostrichidae

Genus : *Rhyzopertha*

Species : *R.dominica*

Morphological feature

The adult is 2-3 mm long with rounded pronotum bent downward at the front where there are transverse rows of teeth centrally with posteriorly flattened tubercles. Between the pronotum and elytra lies the scutellum which is almost square. The elytra have regular rows of punctures and short curved setae posteriorly. Apically the elytra are gently convex rather than flattened. Each antenna has 10 segments; and a loose three segmental club. The sexes may be distinguished by the features of abdominal sternite (Stemley and Wilbur, 1996; Ghorpade and Thyagarajan, 1980) (Plate 6).

Distribution

It occurs mostly in tropical and subtropical regions of the world and causes damage to stored grains in many countries of Asia, Africa, North America and Europe (Stemley and Wilbur, 1996).

Biology

The females prefer laying their eggs in crevices or on the rough surfaces of the grain. After hatching, the larvae use even minute husk cracks to bore into the grain (Potter, 1935). The larvae are white and they do not taper. The legs are rather short and the head, capsule is small relative to the size of the body. The first instar larva is distinctive in having a median posterior spine. Larval development occurs more rapidly on whole grains than on flours at the optimum temperature of 34°C and at

40% R.H. Larvae undergo 3-5 moults and develop to the pupal stage in about 17 days (Howse, 1950) (Plate 8). The pupal stage lasts approximately for three days at the temperature of 34°C and 70% R.H. The adult mates soon after emergence and under favorable condition oviposition may continue for up to four months. There is no definite peak in egg laying. The average numbers of eggs laid per female are 244 at 25°C rising to an average of 418 at 34°C temperature. (Kavallieratos *et al.*, 2009).

#### Food habit

The larvae and adults of *R. dominica* are capable of boring and feeding on a wide range of commodities. Undamaged grains, whole cereals, dried cassava, pulses, lentils, soybeans can be severely damaged by *R. dominica*. They also develop on milled rice and cereal flour, but not highly polished rice (Plate 7).

Plate 6. Adult *Rhyzopertha dominica*

Plate 7. Feeding nature of *Rhyzopertha dominica*

Plant 8. Larva of *Rhyzopertha dominica*

### 3. MATERIALS AND METHODS

The present study was conducted to evaluate some indigenous plants viz Ata (*Annona reticulata*), Karabi (*Nerium oleander*), Neem (*Azadirachta indica*), Biskatali (*Polygonum hydropiper*) and Akanda (*Caloropis gigantea*) leaves extracts against lesser grain borer, *R. dominica* Fab. in the laboratory of the Department of Entomology, Hajee Mohammad Danesh Science and Technology University, Dinajpur during the period from April to December 2012 for their toxic, residual and repellent effects.

#### 3.1 Collection of test plant

The test plant materials of five indigenous plants were collected from the HSTU campus, Dinajpur. The descriptions of the plants are given below.

#### 3.2 Preparation of plant dust and extracts

##### 3.2.1 Processing of plant materials

After collection, they were washed in running water. First of all, the plant materials were kept in laboratory for 7 days for the purpose of air drying followed by one day sun drying before making powder.

### 3.2.2 Preparation of plant dust

Dust was prepared by pulverizing the dried leaves with the help of a grinder. Then the dust was passed through a 25-mesh diameter sieve to obtain fine and uniform dust. These were preserved separately at room temperature in airtight condition in plastic containers till their use in extract preparation (Plate 9).

### 3.2.3 Preparation

The prepared leaf dusts were used for preparation of plant extract. The extracts were prepared according to Chitra *et al.*, (1993). Ten grams of each category of dust were taken in a 600 ml beaker and separately mixed with 100 ml of petroleum ether solvent. Then the mixture was stirred for 30 minutes by a magnetic stirrer and left stand for next 72 hours (Plate 10). The mixture was then filtered through a filter paper (Whatman No.1). The filtered materials were taken into a round bottom flask and then allowed to evaporate the solvent. After the evaporation of solvent from filtrate, the condensed extracts were preserved in tightly corked-labeled bottles and stored in a refrigerator until their use for insect bioassays.

Plate 10. Preparation of plant extracts

### 3.2.4 Preparation of doses

Different doses of plant extracts were prepared separately by diluting the condensed extracts with petroleum ether. Three concentrations (4.0%, 6.0% and 8.0%) along with control of each category of plant extracts were prepared in the petroleum ether solvent prior to insect bioassay (Plate 11). Pilot experiments were conducted to determine the appropriate dose.

## Plate 11.Preparation of doses

### 3.3 Collection and rearing of test insect

#### 3.3.1 Collection of test insect

Collection of lesser grain borer was necessary for rearing to ensure continuous supply of the test insect during the study. Initially, the test insect species, *R. dominica* with infested wheat grains were collected from the godown of pulse seller of Dinajpur town and were maintained in the laboratory of the Department of Entomology, HSTU, Dinajpur, at 27-30°C temperature and 70-75% relative humidity.

#### 3.3.2 Disinfestations of wheat

The wheat grains were spread on black polythene sheet and sun-dried from 9 a.m. to 2 p.m. with air temperature ranging from 32-42°C for five consecutive days. Sun-dried grains were kept in the oven at 45°C for few hours, packed in polythene bag and sealed to avoid future infestation.

#### 3.3.3 Rearing of test insect

The insects were reared on sterilized wheat grains in rectangular jars (14 x 10.5 x 30 cm). Each jar was set up with 10 pairs of adult insects. The mouth of the jar was covered with a piece of cloth fastened with rubber band to prevent contamination and insect escape. After allowing them for free oviposition for a period of 7 days. The adults were removed from each jar and jars were left undisturbed for completing the life cycle of the insect. After adult emerged, one day old adults were sorted from the

wheat grain by sieving and transferred regularly into separate jars with wheat grains. Jars along with insects were then kept in the same place, temperature and humidity. Three to seven days old insects were used for study.

### 3.4 Insect bioassays

Different types of insect bioassay were conducted at 27°C to 30°C temperatures and 70-75% relative humidity to determine the toxicity, residual toxicity and repellency effect. Plant extracts of ata, akanda, karabi, neem, and biskatali in petroleum ether were used with 4.0, 6.0 and 8.0% concentrations.

#### 3.4.1 Toxicity test (Topical application method)

Toxicity test of five indigenous plant extracts against *R. dominica* were conducted according to the method described by Talukder and Howse (1993) with minor modification. Before applying extracts to the thorax of the insect, 10 minutes chilling were done with 4°C in refrigerator. Then 1 µl of prepared solution was applied to the dorsal surface of each insect using a micropipette. Ten insects per replication were treated and each treatment was replicated 3 times. In addition, the same numbers of insects were treated with petroleum ether solvent only for control. After treatment, the insects were transferred into 9 cm diameter petridishes (10 insects / petridish). Insect mortality was recorded at 24, 48 and 72 hours after treatment (HAT).

Original data of the insects were corrected by Abbott's (1987) formula:

$$P' - C$$

$$P = \frac{\text{—————}}{100 - C} \times 100$$

Where,

P= Percentage of corrected mortality

P'= Observed mortality (%)

C= Control mortality (%)

### 3.4.2 Residual toxicity test

Residual toxicity test was conducted according to the method of Talukder and Howse (1993) with some modifications. Three different concentrations of each plant extracts were prepared with the petroleum ether solvent. Then 1 ml. of prepared solution was applied to 50g wheat and mixed properly. Then it was air-dried about 10 minutes. Five pairs of one day old adults were released into the pot containing treated with plant extracts and pot was covered with perforated lid. Three replications were maintained for each of the concentration of the individual plant extracts along with control. All treated pots were kept at ambient temperature ( $32 \pm 3^\circ\text{C}$ ). Insect mortality was recorded at 1, 2, 7, 15 and 21 DAT (Days after treatment).

### 3.4.3 Repellency test

The repellent activities of the five indigenous plant extracts against *R. dominica* were evaluated using the filter paper impregnation method followed by Talukdar and Howse (1994) with minor modifications. First of all, the Whatman No. 40 filter papers were cut into two halves. With the help of a pipette 1ml solution of each plant extract was applied to one half of the filter paper. The treated half and control half was then air-dried. Ten insects were released at the centre of each Petridish and a

cover was placed on the Petridish (Plate 12). Three replication were used for each plant extract and each dose. Then the insect present on each portion were counted at hourly intervals up to 6<sup>th</sup> hour. The data were expressed as percentage repulsion (%PR) by the following formula:

$$\%PR = (N_C - 50) \times 2$$

Where,

%PR = percentage repulsion.

N<sub>C</sub> = The percentage of insects present in the control half.

Positive (+) values expressed repellency and negative (-) values attractency. The average values were then categorized according to the following classes (McDonald *et al.*, 1970):

| Class | Repellency rate(%) |
|-------|--------------------|
| 0     | >0.01 to 0.1       |
| I     | 0.1 to 20          |
| II    | 20.1 to 40         |
| III   | 40.1 to 60         |
| IV    | 60.1 to 80         |
| V     | 80.1 to 100        |

## Plate 12. Repellency test of *Rhizopertha dominica*

### 3.5 Statistical analysis

The collected data were statistically analyzed by completely randomized design (CRD) using MSTAT statistical software. The treatment mean values were adjusted by Duncun's New Multiple Range Test (DMRT). The observed mortality data was also subjected to probit analysis.

## 4. RESULT AND DISCUSSION

The result of various experiments conducted during the study period are presented and discussed under the following subheadings.

### 4.1 Effects of direct toxicity against lesser grain borer

The results of the direct toxicity effects of neem, biskatali, karabi, ata and akanda leaf extracts against lesser grain borer, *R. dominica* are presented in Tables 1 to 3.

Average mortality percentage of lesser grain borer at 24, 48 and 72 hours after treatment (HAT) indicated that neem leaf extract (56.33%) possessed the highest toxic effect which was statistically different from all other plant extract (Table 1). The order of toxicity of five plant extracts against lesser grain borer were found as neem > biskatali > karabi > akanda > ata. Mortality percentages were directly proportional to the time after treatment.

Mortality of lesser grain borer was also differed significantly among all the concentration level at different time interval of different plant extracts. The highest mortality (84.65%) was observed at the maximum concentration of plant extracts while the lowest mortality (30.0%) was

found in minimum concentration. No mortality was observed in control treatment (Table 2).

All plant extracts achieved hundred percent mortality at 72 HAT in 8.0% concentrations except karabi extract (Table 3). Same trend was also observed at 24 and 48 HAT. Average mortality showed that neem leaf extract possessed highest toxicity (mortality, 98.90 %) at maximum concentration whereas lowest (mortality 8.90 %) in karabi extract in minimum concentration

From the above findings it was found that all five plants had toxic effects against lesser grain borer but neem plant extracts showed the highest toxic effect. This findings agreed with Djelatnost and Borah (2009) who found that neem plant extracts are highly toxic than biskatali. The present study also coincides with the earlier findings of Kathirvelu *et al.*, (2009). Therefore, this experiment also confirms the validity of traditional use of leaf of neem, biskatali, karabi, akanda and ata against stored grain pest.

Table 1: Toxicity of different plant extracts on lesser grain borer at different HAT

(Hours after treatment)

| plant extracts used | % Insect mortality(HAT) |        |        |                   |
|---------------------|-------------------------|--------|--------|-------------------|
|                     | 24 HAT                  | 48 HAT | 72 HAT | Average mortality |
| Neem                | 32.33a                  | 66.67a | 70.00a | 56.33a            |
| Biskatali           | 35.00b                  | 50.00b | 57.50b | 47.507b           |
| Karabi              | 36.17b                  | 45.83b | 50.00c | 44.667bc          |
| Akanda              | 27.50c                  | 38.33c | 47.50c | 37.777cd          |
| Ata                 | 13.33d                  | 25.00d | 35.83d | 24.72bc           |
| P- value            | 0.0089                  | 0.0180 | 0.0180 | 0.3333            |
| LSD                 | 1.176                   | 1.419  | 1.060  | 1.221             |
| CV (%)              | 12.29                   | 13.55  | 13.55  | 49.41             |

Mean followed by row the same letter(s) did not differ significantly at 5% level by DMRT.

HAT = Hours after treatment.

Mean followed by column the same letter(s) did not differ significantly at 5% level by MRT.

HAT = Hours after treatment.

#### 4.2 Probit analysis for direct toxicity

The results of the probit analysis for the estimation of LD<sub>50</sub> values and their 95% fiducial limits at 24, 48 and 72 HAT for the mortality of lesser grain borer are shown in Table 4.

The LD<sub>50</sub> values of neem (6.958 µg), biskatali (8.444 µg), karabi (9.191 µg), akanda (10.589 µg) and ata (14.522 µg) at 24 HAT (Table 4) indicated that neem leaf extract was found to be highly toxic. Similarly, neem leaf extract maintain its highest toxicity at 48 HAT while at 72 HAT neem and biskatali extracts showed similar toxicity. The chi-square ( $\chi^2$ ) values of different plant extracts at different HAT were insignificant at 5% level of probability and did not show any heterogeneity of the mortality data.

From the above probit results it is clear that all the tested plants would be more or less effective for controlling lesser grain borer but neem and biskatali will be the most effective. The lowest LD<sub>50</sub> values of neem plant extract indicated that the highest toxic effects against lesser grain borer and agreed with the earlier finding of Kathirvelu *et al.*, (2009). From the above probit results it is concluded that neem will be effective for controlling the lesser grain borer.

Table 4: Relative toxicity (by probit analysis) of different plant extracts treated against lesser grain borer at 24, 48 and 72 HAT

| Name of the plant extracts | No. of insect used | LD 50 values ( $\mu$ g) | 95 % fiducially limits | $\chi^2$ values |
|----------------------------|--------------------|-------------------------|------------------------|-----------------|
| 24 HAT                     |                    |                         |                        |                 |
| Neem                       | 90                 | 6.958                   | 3.646 - 13.278         | .0055           |
| Biskatali                  | 90                 | 8.444                   | 4.251 - 16.770         | .0514           |
| Karabi                     | 90                 | 9.191                   | 4.262 - 19.822         | .0943           |
| Akanda                     | 90                 | 10.589                  | 4.827 - 23.226         | .1735           |
| Ata                        | 90                 | 14.522                  | 3.644 - 57.870         | .3752           |

| Biskatali                  | 90                 | 3.709                   | 1.716 - 8.013          | .0015           |
| Karabi                     | 90                 | 5.771                   | 4.4933 - 7.412         | .2081           |
| Akanda                     | 90                 | 6.349                   | 4.947 - 8.148          | .0476E-04       |
| Ata                        | 90                 | 9.342                   | 5.466 - 15.966         | .1611           |
| 72 HAT                     |                    |                         |                        |                 |
| Neem                       | 90                 | 2.744                   | 1.630 - 4.755          | .3102           |
| Biskatali                  | 90                 | 2.784                   | 1.449 - 5.195          | .0730           |
| Karabi                     | 90                 | 3.432                   | 2.131 - 5.528          | .0339           |
| Akanda                     | 90                 | 4.127                   | 2.940 - 5.794          | .1356           |
| Ata                        | 90                 | 5.924                   | 4.989 - 7.034          | .0116           |

HAT= Hour after treatment

Values were based on three concentrations, three replications of 10 insects each.

$\chi^2$  = Goodness of fit

The tabulated value of  $\chi^2$  is 5.99 (d. f=2 at 5% level)

#### 4.3 Probit regression lines for direct toxicity

The probit regression lines for the effect of five plants extracts (neem, biskatali, karabi, akanda and ata) are presented in figure 1, 2 and 3. The insect mortality rate showed positive correlation with doses in all cases. The probit regression lines for the effects of five plant extracts on lesser grain borer showed a clear linear relationship between probit mortality and their log doses. The calculated probit regression equations of five

plant extracts are  $Y = 1.087x + 4.088$ ,  $Y = 1.436x + 3.676$ ,  $Y = 1.436x + 3.596$ ,  $Y = 1.820x + 3.134$  and  $Y = 1.620x + 3.13$  for neem, biskatali, karabi, ata and akanda respectively at 24 HAT (Fig. 1). Comparing among these lines, neem showed the higher probit mortality. The calculated probit regression equations of five plant leaf extracts at 48 HAT are  $Y = 0.875x + 4.767$ ,  $Y = 1.493x + 4.149$ ,  $Y = 2.436x + 3.156$ ,  $Y = 2.433x + 3.041$  and  $Y = 2.226x + 2.825$  for neem, biskatali, karabi, ata and akanda respectively (Fig. 2).

At 72 HAT the probit regression equations were calculated as  $Y = 3.699x + 3.318$ ,  $Y = 2.966x + 3.672$ ,  $Y = 2.760x + 3.515$ ,  $Y = 2.877x + 3.233$  and  $Y = 3.673x + 2.168$  for neem, bskatali, karabi, ata and akanda respectively (Fig. 3). Among the five lines, the regression line for neem plant extract also showed the highest probit mortality.

The probit regression lines became steeper as doses increased. Because the adult insects were treated with more toxins for the same period at higher doses.

Figure 1. Relationship between probit mortality and log doses of different plant extracts on lesser grain borer, *R. dominica* at 24 HAT.

Figure 2. Relationship between probit mortality and log doses of different plant extracts on lesser grain borer, *R. dominica* at 48 HAT

Figure 3. Relationship between probit mortality and log doses of different plant extracts on lesser grain borer, *R. dominica* at 72 HAT

#### 4.4 Residual effects against lesser grain borer

The result of residual toxic effects of neem, biskatali, karabi, akanda and ata plant extracts on lesser grain borer, *R. dominica* are presented in Tables 5 to 7.

Average mortality percentage of lesser grain borer at 1, 2, 7, 15 and 21 days after treatment (DAT) indicated that neem plant extract (61.67%)

possessed highest toxic effect which was statistically different from all other plant extracts (Table 5). The orders of toxic effect of five plant extracts against lesser grain borer was: neem > biskatali > karabi > akanda > ata. Mortality percentages were also directly proportional to the time after treatment.

Mortality of lesser grain borer was also differed significantly among all the concentration level of different plant extracts. The lowest average mortality (30.80%) was found in minimum concentration (4%) but the highest (85.15%) was observed at the maximum concentration (8%) of plant extracts and no mortality was observed in control treatment (Table 6).

Considering the interaction of plant extracts, doses and time, neem plant extract possessed the highest residual effect (average mortality, 98.97%) followed by biskatali (average mortality 95.20 %) against lesser grain borer at maximum dose. Same trend was also observed at 1, 2, 7 15 and 21 DAT. Mortality percentages were differed significantly between plant extracts and doses (Table 7).

The study of residual effect of plant extracts was agreed by the findings of Rajendran *et al*/ (2008), who found that neem plant extracts possessed highly toxic substances than biskatali.

Table 5: Toxicity of different plant extracts on the lesser grain borer at different DAT  
(Days after treatment).

| Name of the | % Insect mortality(DAT) |
|-------------|-------------------------|
|-------------|-------------------------|

| plant extracts | 1 DAT  | 2 DAT  | 7 DAT  | 15 DAT | 21 DAT | Average mortality |
|----------------|--------|--------|--------|--------|--------|-------------------|
| Neem           | 48.33a | 52.35a | 63.67a | 70.00a | 74.00a | 61.67a            |

#### 4.5 Probit analysis for residual toxicity

The results of the probit analysis for the estimation of LD<sub>50</sub> values and their 95% fiducially limits at 1, 2, 7, 15 and 21 DAT for the mortality of lesser grain borer are shown in Table 8.

The LD<sub>50</sub> values of neem (18.543 µg), biskatali (29.817 µg), karabi (30.937 µg), akanda (34.883 µg) and ata (31.204 µg) at 1 DAT (Table 8) indicated that neem plant extracts possessed the highest toxicity while lowest in akanda against lesser grain borer. Similarly, neem plant extract maintained its highest toxicity at 2, 7, 15 and 21 DAT. The chi-square ( $\chi^2$ ) values of different plant extracts at different hours after treatment were insignificant at 5% level of probability and insignificant  $\chi^2$  value did not show any heterogeneity of the mortality data.

Athanassiou *et al.*, (2008) studied the plant extract of neem against adults of *R. dominica* and found that at 100 ppm neem oil showed 100 % adult mortality after 14 days exposure. The present study also indicated that neem plant extract has lowest LD<sub>50</sub> values and highest residual effects on lesser grain borer and agreed with the earlier findings of Kathirvelu *et al.*, (2009). From the probit results it is clear that neem will be effective for controlling the lesser grain borer.

Table 8: Relative toxicity (by probit analysis) of different plant extracts treated against Lesser grain borer at 1, 2, 7, 15 and 21 DAT

| Name of the plant extracts | No. of insect used | LC 50 values (ug) | 95 % fiducially limits | $\chi^2$ values |
|----------------------------|--------------------|-------------------|------------------------|-----------------|

DAT= Day after treatment, Values were based on three concentrations, three replications of 10 insects each,  $\chi^2$  = Goodness of fit, The tabulated value of  $\chi^2$  is 5.99 (d. f=2 at 5% level)

#### 4.6 Probit regression lines for residual toxicity

The probit regression lines for the effect of five plants extracts (neem, biskatali, karabi, akanda and ata) are presented in figure 4 to 8 against lesser grain borer. The insect mortality rate showed positive correlation with doses in all cases. The probit regression lines for the residual effects of five plant leaf extracts on lesser grain borer also showed a clear linear relationship between probit mortality and their log doses. The probit regression lines became steeper as doses increased.

The calculated probit regression equations line of five plant extracts at 1 DAT were:  $Y = 1.413x + 3.187$ ,  $Y = 1.318x + 3.093$ ,  $Y = 1.421x + 2.834$ ,  $Y = 1.719x + 2.454$  and  $Y = 2.011x + 1.922$  for neem, biskatali, karabi, ata and akanda respectively (Fig. 4). Comparing among these lines, neem showed the higher probit mortality.

The calculated probit regression equations line of five plant extracts at 2 DAT were:  $Y = 1.398x + 3.525$ ,  $Y = 1.569x + 3.272$ ,  $Y = 1.376x + 3.182$ ,  $Y = 2.203x + 2.376$  and  $Y = 1.719x + 2.454$  for neem, biskatali, karabi, ata and akanda respectively (Fig. 5). Neem also showed the highest probit mortality at 2 DAT.

The calculated probit regression equations line of five plant extracts at 7 DAT were:  $Y = 3.056x + 2.640$ ,  $Y = 6.067x + 0.592$ ,  $Y = 3.023x + 2.235$ ,  $Y = 2.954x + 2.0.8$  and  $Y = 3.919x + 0.840$  for neem, biskatali, karabi, ata and akanda respectively (Fig. 6). Comparing among these lines, neem also maintained its highest probit mortality. Similar trend of probit mortality lines were found at 15 and 21 days after treatments.

Kathirvelu *et al.*, (2009) studied to assess the effect of botanicals *Azadirachta indica* and *Pongamia glabra* on *R. dominica* in stored rice and the results revealed that mixing neem oil at 30 ml per kg of grains was effective against the pest, recording 57.95% mortality. and agreed with the present study.

Figure 8. Relationship between probit mortality and log doses for residual effect of different plant extracts on lesser grain borer, *R. dominica* at 21 days

#### 4.7 Repellent effect on lesser grain borer

The repellency effect of five plant extracts is presented in Table 10. Neem, biskatali, karabi, ata and akanda plant extracts showed medium repellent effect against lesser grain borer. Among the five plant extracts tested, neem showed the highest mean repellent effect (37.79%) followed by biskatali (36.12%), karabi (35.55%), akanda (34.17%) and ata (22.51%). However, these differences were not statistically significant. In some cases, repellency rate decreased with the progress of time. The rate of repellency differed with the extract type. All plant extracts were in the same repellency class i.e. class II.

Mean repellent effect of different plant extracts in different dose level on lesser grain borer is presented in Table 10. The repellency was influenced by the concentration of extracts. Repellency rate did not

increase proportionally with the doses. The highest mean repellency effect was found with 8% dose extract (46.21%) (Table 10).

Interaction repellent effect of different plant extract and their doses on lesser grain borer at different HATs is presented in (Table 11). The highest mean repellency effect was found on 8% dose of neem extract (82.20%).

Jilani and Saxena (1990) observed that the repellency of compounds with low molecular weights and high volatility decreased rapidly over time. The present study has shown that neem and biskatali leaf extract have moderate repellent effects on lesser grain borer and agreed with the earlier findings of Bowery *et al.*, (1984). This study is proved our traditional use of leaf of neem, biskatali, karabi, ata and akanda to protect stored grain pests.

Table 9: Repellency effects of different plant extracts on lesser grain borer at different HATs

## 5. SUMMARY AND CONCLUSION

The present experiment was undertaken to study the effectiveness of neem, biskatali, karabi, ata and akanda plant extracts against lesser grain borer in the laboratory of the Department of Entomology, HSTU, Dinajpur during the period from April to December 2012. The petroleum ether extracts of these plants were evaluated for toxic, residual and repellent effect against lesser grain borer, *R. dominica*.

Mortality percentage of lesser grain borer at 24, 48 and 72 HAT indicated that neem plant extracts possessed the highest toxic effects among all the plant extracts. Mortality percentage was also found directly proportional to the level of concentrations of plant extracts and to the exposure period.

The lowest LD<sub>50</sub> values of neem plant extract at 24, 48 and 72 HAT indicate that neem plant extract possessed highest toxic effects. The Chi-square values of different plant extracts at different hours after treatment are insignificant at 5% level of probability and did not show any heterogeneity of the mortality data.

Mortality percentage for residual toxicity of lesser grain borer at 1, 2, 7, 15 and 21 DAT indicated that neem extracts also possessed the highest toxic effects comparing to biskatali, karabi, ata and akanda. Mortality percentage was also found directly proportional to the level of concentrations of plant extracts and to the exposure period. The lowest

LD<sub>50</sub> values of neem plant extract at different DAT also indicate that neem plant extract possessed highest toxic effects. The Chi-square values of different plant extracts at different days after treatment are insignificant at 5% level of probability and did not show any heterogeneity of the mortality data.

The repellent effect of neem, biskatali, karabi, ata and akanda extracts showed that the five plant extracts had moderate repellent effect on lesser grain borer. The highest mean repellency was observed in neem extract for lesser grain borer, *R. dominica* comparing to bskatali, karabi, ata and akanda. In maximum cases the repellency rate decrease for increasing of exposure period.

Our country imports a large amount of insecticides to minimize the severe damage caused by insect pests every year. As a result production costs are increased for buying insecticides. Botanical materials as insecticides can be used as substitute as these substances are not only of low cost, but also have less environmental impact in terms of insecticidal hazards. Finally, it is concluded that the present study will be very useful in controlling our storage pest successfully and will help us to save precious foreign currency from importing synthetic insecticides.

#### Recommendations:

1. It is recommended that farmers can use leaf extract of neem, biskatali, karabi, ata and akanda as botanical insecticide against lesser grain borer as they showed toxic effect.

2. Farmers may use leaf extract of neem, biskatali, karabi, akanda and ata in their storage as repellent against lesser grain borer because they have moderate repellent effect.
